* *Consider using a 2D grid instead of a list.* Instead of listing patients with one patient per row, the interface can use a 2-dimensional grid with all the patient information (name, room, age etc.) presented in a single taller and narrower cell. Square targets are easier to select than long skinner ones, which would reduce the slip errors. The drawback is that it may be less obvious how the patients are sorted or to compare particular attributes (e.g. age).

During Task 3: Verify selection
Clinicians should be given opportunities to detect selection errors before order entry.

***** *Highlight on departure*. Highlighting the selected name or row while departing from the patient list can help users verify that the selection was correct[28]. In our prototype, when users selects a patient row by a mouse click, all the other rows fade out in 500 millisecond, leaving only the selected row visible on the screen (Figure 5).
* *Highlight on arrival.* The ordering screen can also display the patient information header first so the clinician can verify that the correct record has been opened. The temporary highlight only takes a fraction of a second so it does not slow down the interaction or require additional action. In our prototype, the patient name appears on the top-left corner of the screen (where readers usually start scanning or reading a screen) then the rest of the patient

identification information appears next to the name. After one second, the rest of the interface becomes visible allowing clinicians to place the order. Our prototype allows adjustment of all animations delays and informal testing suggests that keeping all delays below a second is preferable. This is in contrast with techniques such as ID Reentry might require 10-15 additional seconds for each patient selection.

***** *Use animated transition.* Clinicians' attention can be drawn to the patient name during the entire transition between screens. For example an animated transition can smoothly glide the selected name from its position in the patient list to its final position in the header of the order screen. Again the animation should be fast enough not to hamper the workflow, and slow enough to serve its purpose (i.e. attract attention to the selected name, and teach the final location of the name in the header of the order screen to new users). An adaptive approach might be helpful. For the system could detect the probability of a slip error (e.g. when the mouse click was very near the edge of a row) and slow the transition a bit more to increase the chance of error detection.

**Use a visual summary of the patient history.* A thumbnail of the timeline of the patient history could be displayed next to the patient's photo. A visual summary is faster to "read" than a textual description of the patient's history. Instead of the full history the last two or three significant events in the time line might help clinicians distinguish between patients.

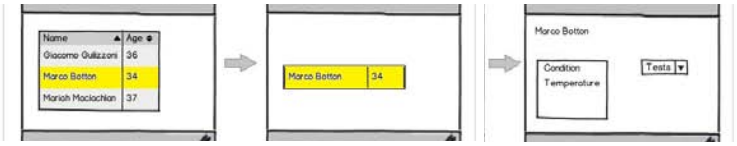

Figure 5: Highlight on departure (mock-up)

During Task 4: Place order

* *Keep the patient header visible at all times.* The header should not be allowed to scroll out of view

* *Maintain consistency between screens*. When switching from the patient list to the order screen, font-type, capitalization and color used to display the patient's basic information should not change abruptly. Such changes are visually distracting and make it harder to perceive differences between the selection screen and the order screen.

* *Use clinical decision support.* For example Galanter et al. demonstrated a reduction of wrong-patient medication errors after implementing a clinical decision support system to prompt clinicians for indications when certain medications were ordered without an appropriately coded indication on the problem list.[27.]

* *Consider side-by-side display of detailed patient information and order information*. For example, a patient's medication history is useful for clinicians ordering a new medication, and that medication history will be fairly unique to each patient so may help recognize selection errors.

During step 5: Confirmation after order entry

The goal here is to remind users of the patient identity before they finish their work:

* *Include the identity of the patient in the Submit button.* This simple technique increases the chances that clinicians will pay attention to the name or photo as they place the order. If there is no space to include the patient information on the submit button a tooltip can be used, but this is less desirable and it should be carefully designed to pop up consistently as the mouse approaches the submit button. A confirmation dialog box can serve the same purpose, but would require an additional reorientation and action from the user. It seems preferable to leave the dialog box option for situations where Decision Support can draw attention to a specific potential error (such as ordering a pap-smears for a male patient)

***** *Consider placing the submit button near the patient information.* Alternatively the submit button can be positioned near the header and the patient information so clinicians are more likely to glance at the patient's name and photo before the order submission. This may require changing button placement guidelines for the entire application.

During Task 6: Report error

* *Allow placing the same order for the correct patient without starting entirely from scratch.* Correcting the error is another aspect of the problem. Canceling or invalidating the order and re-entering a new order from scratch takes time; so we recommend that if clinicians recognize that an error was made, they be able to keep at least some of the order information and assign it to the correct patient. This technique will not only speed up the creation of the new order and will make it easier to track the occurrence of patient selection errors.

* *Report errors with proper feedback.* When an error has been made, allow reporting of the error. If a clinician

simply cancels an order then the reason of the error is not clear. It can be that the wrong patient was selected, or a wrong medication or simply that the situation has changed. The cancellation dialog box can be augmented to include a list of possible reasons for the cancellation. Collecting reasons for cancellation will provide a basis for requesting improvements based on what type of errors are most common for that system. For example, if most of the errors were due to selecting an adjacent row then the interface can be improved by inserting gap between the rows or resizing the row height. If a majority of errors are caused by similar names, then adding similarity algorithms and warnings about similar names will be most helpful. Most of the techniques proposed here have implementation costs, so error reports will be most useful to guide the selection of improvements to be made.

Limitations and Evaluation Challenges

This study has several limitations. We catalog many possible user interface techniques, and discuss why they are likely to be useful but the new techniques we propose have not been tested in clinical situations. Some of the techniques are very easy to implement and obvious payoffs (e.g. putting patient's names on the Submit button, or not truncating names) so we are very confident they can be implemented immediately without extensive evaluation. Other techniques require more complex implementation and we cannot predict the exact payoff (e.g. calculating similarity of names) so clinical evaluations may be needed to measure the benefits, but they can be safely deployed after adequate interface usability testing. The benefits of other techniques such as animated transitions or list filtering is fairly well documented in Human-Computer Interaction research (see prior work section) and used extensively in modern interfaces such as mobile devices. Those techniques may not require formal evaluations in clinical settings before they can be deployed widely, but will require careful usability evaluations (e.g. animation needs some user testing to adjust transition speed). On the other hand, long-term monitoring and evaluations in clinical settings will be beneficial to measure if clinicians' attention is still attracted to the patient identity after months of animation or highlighting use.

The main challenge faced by Human-Computer Interaction researchers is that it is difficult to simulate a hospital environment. Spontaneous errors are rare and unlikely to occur in laboratory settings. One approach is to "plant" errors and measure how the interface helps users to notice and recover from those errors[18, 28]. Another possible technique might be to simulate extremely disrupted situations (e.g. very high levels of interruptions or dual parallel tasks) so errors are more likely to be made and experiments can measure which techniques help reduce the effect of interruption. None of the laboratory methods can adequately evaluate the long-term effect of the proposed techniques.

Long-term in-situ evaluations will require both accurate detection of the errors and safety monitoring (as recommended by Sittig and al.[29]) and participation of vendors to build novel techniques into their user interfaces. Both Wilcox[8] and Adelman[7] used self-corrections to estimate the number of errors made (i.e. orders placed that were retracted within 10 min, and then reordered by the same provider on a different patient within 10 min of retraction.) Wrong patient errors are often only detected when reported by pharmacists or patients, sometimes after the patients have suffered the consequences of the errors. Elder et al.[30] showed that the perceived benefit of improving the patient care system can encourage clinicians to report errors. A voluntary error reporting and tracking system established in Duke University's Department of Community and Family Medicine succeeded in increasing the rate of error reporting by encouraging the clinicians to improve their system, involving them in the care improvement process, and keeping their identity confidential[31]. Instead of blaming the clinicians they directed their focus towards improving the overall health care system.

A/B testing[32] is a new method now commonly used to improve e-commerce websites. It is a type of between-subject test where participants are presented with one of two versions of an interface while doing their work. With adequate measurement of the error rates conducting long term A/B testing might then become possible within operational EHR systems, and lead to evaluations in real situations. With adequate IRB review each novel technique presented here could be tested by presenting the original version A to one group of clinicians and version B (with the suggested techniques) to another group of clinicians.

Conclusion

After reviewing the prior work on wrong patient selection and applying our expertise in Human-Computer Interaction design, we cataloged 27 user interfaces techniques that have the potential to reduce the occurrence of

costly and potentially life-threatening errors. Multiple techniques are available at every task of the process of recall, selection, verification, order entry, confirmation and reporting. Eighteen of those techniques were implemented and demonstrated. Feedback from clinicians and user interface designers enabled us to refine our designs, but scientific evaluation of those techniques remains a challenge. While some techniques may be evaluated in laboratory settings, more rapid progress will be made when hospitals and clinics put in place adequate incentives for reporting errors or near misses, and researchers have agreements with vendors to assist in the testing of the proposed techniques. Nevertheless many techniques have low implementation costs, low risk and high probable impact and we believe do not require long-term evaluation before they can be implemented. One such example we hope to see implemented in all EHR systems is the inclusion of the name of the patient on Submit buttons. Drawing attention to and collecting accurate data about medical care errors, is exactly what advocates of the Learning Health System promote to accelerate continuous improvement. In addition, these same techniques could have payoffs for many consumer and business applications, in which selections of people (passengers, college applicants, etc.), products (books, films, etc.), or services (flights, shipping, etc.) are made.

Acknowledgments

This work was partially supported by Grant No. 10510592 for Patient-Centered Cognitive Support under the Strategic Health IT Advanced Research Projects Program (SHARP) from the Office of the National Coordinator for Health Information Technology. We also want to thank Zach Hettinger, Meirav Taieb-Maimon, and all our Sharp project colleagues who helped along the way by provided feedback on the prototype and paper.

Abstract

BACKGROUND: Delirium is a common syndrome in elderly hospitalized patients that is correlated with poor outcomes and higher costs yet health care teams often overlook its diagnosis and treatment. Poor data quality in EHR systems can be contributing to this as a common tool teams use to communicate and record data about their patients.
METHODS: Data were gathered from 30 patients chosen randomly that spanned various data domains in the EHR. These were analyzed for concordance as an indicator of data quality.
RESULTS: Concordance was high between the physician and nursing narrative documentation. The other domains of data were drastically less concordant.
DISCUSSION: The low concordance between structured and narrative data domains suggests that clinicians are forgoing the features available in modern EHR systems and opting to work in narrative. For informatics, this can be troubling as narrative data are difficult to compute.

Background

Delirium is a transitory syndrome that is characterized by a sudden and temporary change in mental status exhibiting a deficiency in cognition or attention. Individuals with this syndrome can have symptoms such as distracted attention or difficulty holding conversations. Highly prevalent in hospitalized patients, especially in those over age 65 [1], delirium has been shown to correlate with increased hospital length of stay, increased mortality at discharge and at 12 months, reduced independence, and greater risk of institutionalization [1-4]. Delirium is a significant burden for nursing staff, as sitters or increased monitoring is often required to care for the patient [5]. All of these effects lead to higher costs of care and poorer outcomes [6], making prevention, mitigation and treatment a high priority. Risk factors of delirium include medications, acute disease, location (e.g. intensive care units), age over 65, and comorbidities [6].

The transitory nature of delirium makes it difficult to diagnose and treat, as the affected individual may not display symptoms during any particular evaluation by a health care provider. Over 50% of delirium may go undetected [7] and 50% of patients are discharged home with delirium [2]. Difficulties in detection make a definitive diagnosis of delirium difficult to ascertain. Therefore, the diagnosis of delirium is largely a subjective process that varies depending on the experience of the health care provider working with the individual [7]. Many objective tools exist that can assist with diagnosis, such as the Confusion Assessment Method (CAM), and can consistently evaluate and score a subject's level of delirium [8]; however, these tools are not typically utilized unless initial signs and symptoms of delirium are already detected [9]. Specialized teams of mental health experts can also be engaged to improve the diagnosis of the presence of delirium and to explore mechanisms for treatment. However, these consults must be ordered which again relies on initial detection of symptoms. These factors, coupled with delirium's inconsistent presentation, make routine identification and diagnosis poor and unreliable. Awareness of the risk factors and symptoms must be present at all times by all members of the health care team to detect any subtle signs of its presence. Medications and infection are the two most common cause of delirium. Early detection would significantly decrease patient harm for both situations. Furthermore, once symptoms are identified they must be communicated to the entire team so appropriate prevention and mitigation can be enacted. Without this constant awareness and communication, the immediate risk of an adverse event due to delirium is increased significantly [10].

Communication within the health care team regarding delirium remains poor [10]. Many different forms of communication exist through which team members can convey suspicion or progression of delirium. While some of the communication occurs face-to-face, facilities that utilize electronic health records (EHRs) can capture some communication electronically and make it available to the entire team. The EHR becomes a comprehensive record

of the patient's status and progress. Health care team members utilize the EHR to stay current with their patients. Ultimately, the EHR is a tool for communication for the individual clinician, team and institutional level stewardship

Previous studies show that documentation quality within an EHR is generally poor. Data are often recorded inconsistently or not read by other team members [11, 12]. The result is that clinicians must expend considerable energy and cognitive effort in looking for inconsistent information, validating the information and ensuring accuracy [13]. Currently no tools exist that display the degree to which recorded information is inconsistent, a valuable tool to support decision-making for clinicians. In the case of delirium, its transitory nature coupled with it being a change in mental status (making determination of baseline data a key piece of information), as opposed to physical ailment, lead to vagueness and uncertainty regarding the quality of mental health data. As a result, it is commonly undiagnosed and untreated. Given the difficulty of identifying delirium and the deficiency of quality in EHR documentation, it is not surprising that delirium is grossly undertreated.

Data concordance plays a major role in documentation quality [14]. We conducted this study to determine the concordance of data on delirium as an indicator of document quality within the Veterans Affairs (VA) EHR system. We compiled data from International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) codes, problem lists, physician and nursing narrative notes, physician orders, and CAM assessments.. By examining the concordance of data on delirium we can inform health care team members about discrepancies. This information may motivate them to improve the quality of the data in the EHR.

Methods

We used a cohort study design to determine the degree of concordance within EHR data. A cohort of 30 patients were randomly chosen out of 528 patients admitted to the two medical units at the VA Medical Center in Salt Lake City, Utah. The cohort consisted of patients who were over the age of 65 (a risk factor for delirium), and an inpatient stays that occurred during the 2013 calendar year. We chose a single, whole, contiguous year to eliminate the possibility of temporal confounding. Finally, patients included were from the Acute Medicine and Telemetry units as these are the main medical units at this facility. We specifically excluded ICU, psychiatry and surgery for this pilot work in order to identify data collection practices on these vulnerable units.

For the 30 randomly selected patients in the cohort, we performed retrospective chart reviews for their most recent inpatient stay. These reviews gathered data from EHR domains including the following: ICD-9-CM diagnosis codes (Table 1 lists the codes used), problem list entries, physician orders, physician and nursing narrative notes, CAM assessments, and mental status assessments. To determine the presence of delirium in diagnosis codes we relied on the set of terms derived from Hope et al. [15], who performed a similar enumeration (but did not randomly select patients). As in this study, orders for restraints and sitters and CAM assessments were included. In addition, we included medication review that was not done in their study. Finally, physician and nursing narrative notes were included since they are predominantly used to collect the status and progress of the patient throughout their stay as well as the thought processes of the health care team.

Once the data were gathered, the narrative note reviews were analyzed for inter-rater reliability to ensure consistent evaluation. We then performed an analysis of heterogeneity between the different data domains. The data were categorized on each patient for each domain with a binary evaluation: evidence of delirium exists or not.

Table 1. ICD-9-CM Codes Considered Evidence of Delirium

Code	Description
290.3	Senile dementia with delirium
291	Alcohol-induced mental disorders
291.0	Alcohol withdrawal delirium
292	Drug-induced mental disorders
292.81	Drug-induced delirium
293	Transient mental disorders due to conditions classified elsewhere
293.1	Subacute delirium
780.09	Other alteration of consciousness

Results

Overall, a total of 10 patients had some reference to delirium in their medical record. Of those 10, 9 had agreement between the narrative notes of nurses and physicians. Within those 9, 3 had ICD9 codes representing delirium and 1 had a problem list entry (it was not one of the patients identified in the ICD9 codes). Table 2 presents the distribution of positive findings.

Table 2. Occurrence of delirium

Source	Cases Identified	Notes Reviewed	Distinct Terms
MD Notes	9	178	15
RN Notes	9	298	14
ICD-9-CM Codes	3		
Problem List Entries	1		
Orders	0		

To test concordance an overall Kappa was computed across all sources using presence/absence as the categories and the sources as the "judges". The Kappa was moderately low, despite a baseline prevalence of about 35%. (Kappa= 0.33). Specific contrasts were done to assess the degree of association between nurses and physicians (82% agreement or Kappa = 0.83) and between ICD9 codes and ANY narrative note (27% agreement and Kappa = 0.36) and between ICD9 and the problem list (Kappa= 0.47). Statistical inference was limited due to small sample size.

Patients in the cohort took an average of 15 (range = 0 to 33) unique medications as outpatients the year prior to their hospitalization. While inpatient, the average number of unique medications remained the same at 15 medications per patient during their stay. The number of unique medications did not correlate with the presence or absence of delirium symptoms in our cohort OR the presence of an ICD-9-CM diagnosis code for delirium. Two patients in the cohort (20% of patients with delirium) received pharmacological treatment with an antipsychotic (haloperidol) to help manage symptoms of delirium/agitation, one with an ICD-9_CM code for delirium and the other without. Both patients had documentation of delirium in the narrative text.

Further assessment of the narrative text (495 progress notes) revealed significant variation in how the different roles used narrative text to document delirium. Nurses almost uniformly used somewhat structured terms, such as oriented times 3 or 4. In contrast, the terms that physicians were used were more collogue and informal. Table 3 lists most of the terms used by the different roles in their text.

Table 3. Terms and references used by different roles in narrative text

MD Terms	RN Terms

dementia/tremors/Parkinson's	*sundowner*
hx delirium/delirium precautions	

Discussion

The results show there is a high degree of concordance regarding the presence/absence of delirium within the clinical narrative documentation but little outside of that domain. Differences were found in the nature of the

narrative. In contrast, ICD9 codes only represented a little less than a third of those documented in text and did not particularly correlate with physician notes, orders (there were no orders in this set) or medications. All of the documents for the reviewed patients had minor variability in regards to frequency and agreement of mental status evaluations.

The consistent evaluation and recording of mental health status, especially for nurses., in the narrative notes may have been facilitated by the regular use of note templates within VA hospitals. These templates include a section for mental health evaluation. Thus nearly all physician and nurse narrative documents reviewed noted the mental health status of the patient. The only exceptions to this rule were notes documenting a non-routine event such as helping a patient to the bathroom. The ubiquity of mental status evaluations led to the detection of acute episodes of delirium in these narrative notes. The substantial literature attesting to the neglect of delirium detection and treatment made this a welcome finding. The result shows that the VA making a concerted effort to keep mental health status at the forefront of their care model. It also demonstrates that the most concordant and, hence, reliable information is still locked away in narrative notes. This information can only be programmatically utilized through complicated natural language processing (NLP) technologies. Ultimately, we can interpret this concordance as an indicator of high quality narrative documentation at the VA by the nurses.

Discrete and coded data, were almost completely deficient in representing any changes to the patient's mental status. Interestingly these are data most likely to be used for computerized decision support (CDS). Orders for the pharmacological management of delirium did not correspond to the number of patients with documentation of delirium. Medications typically associated with delirium adverse events did not seem to correlate with the presence or absence of delirium either however. However, the study was under powered to detect such a difference. Additionally, only a small percentage of case records were found to have delirium indicated in either the billing ICD-9-CM codes or the active problem list. Other studies, such as Inouye et al., had comparable results. They found ICD-9-CM codes had a sensitivity of 3% and specificity of about 99% [16]. These findings mean that where delirium was coded the code was accurate, but that up to 93% of delirium cases were missed. Typically ICD-9-CM coding is done after the patient has been discharged as a way to enumerate the diagnoses that were treated during the inpatient episode. At non-VA institutions these codes are required to justify charges. However, clinical personnel do not assign ICD-9-CM codes. They are determined by trained coders, who scan the documentation looking for diagnoses. Since Delirium does not often appear on problem lists, the evidence we detected in the narrative notes was related to the recording of mental health status checks. Coders are by law prohibited from generating diagnoses not listed explicitly in the record. Therefore, they may not read them in the level of detail required to find the necessary evidence to contact a physician to inquire whether a patient had delirium. In this case, using concordance as an indicator, the quality of ICD-9-CM codes are poor, leading one to doubt the validity of knowledge, research or otherwise, gained from them.

The lack of delirium being recorded in the problem list is intriguing but not uncommon [17]. Problem lists are a common component in modern EHR systems. They are meant to facilitate a shared mental model of the issues surrounding a patient. The lack of recording suggests that they are seldom used at the VA for delirium. This is unfortunate as there is evidence that shows consistent problem list use improves care [18]. As many CDS systems utilize coded data in problem lists, a lack of accurate information could lend to more harm than good being done for the patient. Government initiatives such as Meaningful Use seek to mandate the use of problem lists. Overall, without a change in the integration of problem lists are integrated into routine patient care they will most likely continue to provide minimal usefulness to the health care team and informatics in general.

There are a few limitations in this study worth noting. The first is that the data analyzed were limited to a single VA hospital and the results may not be generalizable to other hospitals. The methodology with which this VA hospital cares for and document its patients could be unique. We were limited by a small sample size due to the time and expense required to manually review narrative notes. The time and effort limitation reinforces the need for reliable discrete data. Finally, this study focused on delirium, it cannot be assumed that the same pattern occurs for any other diagnoses. Future studies could broaden the scope of this study to determine if similar patterns exist in other health care facilities as well as with other diseases and diagnoses.

Conclusion

This study demonstrates that the highest quality data are those that are the hardest to obtain. Moreover, it reaffirms the clinician's preference for narrative in recording patient information. For initiatives involving CDS, research, or other data dependent ventures the implications of this research are that accessing the information within narrative notes will be vitally important.

The data pertaining to delirium in the VA EHR system have very little concordance between the narrative documents and the discrete coded data, while the narrative domains alone demonstrate a high degree of concordance, but a substantial degree of 'fuzziness". The EHR as a tool to facilitate communication and collaboration between health care team members has not been embraced and continues to function as merely a document repository. This challenges the utility of feature-rich systems compared to the cost to implement and maintain them as well as restates the clinicians' preference for narrative-based information exchange.

Abstract

Background: *Regulations and privacy concerns often hinder exchange of healthcare data between hospitals or other healthcare providers. Sharing predictive models built on original data and averaging their results offers an alternative to more efficient prediction of outcomes on new cases. Although one can choose from many techniques to combine outputs from different predictive models, it is difficult to find studies that try to interpret the results obtained from ensemble-learning methods.*

Methods: *We propose a novel approach to classification based on models from different hospitals that allows a high level of performance along with comprehensibility of obtained results. Our approach is based on regularized sparse regression models in two hierarchical levels and exploits the interpretability of obtained regression coefficients to rank the contribution of hospitals in terms of outcome prediction.*

Results: *The proposed approach was used to predict the 30-days all-cause readmissions for pediatric patients in 54 Californian hospitals. Using repeated holdout evaluation, including more than 60,000 hospital discharge records, we compared the proposed approach to alternative approaches. The performance of two-level classification model was measured using the Area Under the ROC Curve (AUC) with an additional evaluation that uncovered the importance and contribution of each single data source (i.e. hospital) to the final result. The results for the best distributed model (AUC=0.787, 95% CI: 0.780-0.794) demonstrate no significant difference in terms of AUC performance when compared to a single elastic net model built on all available data (AUC=0.789, 95% CI:0.781-0.796).*

Conclusions: *This paper presents a novel approach to improved classification with shared predictive models for environments where centralized collection of data is not possible. The significant improvements in classification performance and interpretability of results demonstrate the effectiveness of our approach.*

Introduction

The widespread use and availability of Electronic Health Record (EHR) data are responsible for numerous studies and should result in measurable improvements of the healthcare quality level in the coming years. However, most of the available data from healthcare repositories nowadays are still very limited in terms of heterogeneity and most studies use local data repositories [1, 2]. The Health Information Technology for Economic and Clinical Health HITECH act of 2009 was one of the most recent incentives of the US government to establish healthcare data exchange systems. However, in many cases legal and privacy concerns is still the main reason against data exchange between hospitals or healthcare providers [3]. On the other hand, researchers are often faced with a complex task of data integration even in cases where an agreement for data integration is reached [4]. On the other hand, one can observe a growing number of studies that use millions of records to build predictive models that will be used on the future repositories of EHRs [5-7].

Multiple privacy-preserving distributed classification models with applications in healthcare were proposed recently. Mathew and Obradovic [8] proposed a distributed knowledge-mining framework based on a decision tree classifier. Their approach allows heterogeneous data schemas to build a decision tree using locally abstracted data – i.e. no raw data needs to leave the hospital. Another distributed approach was proposed in [9] where distributed distance metric learning was used to assess patient similarity. A recent approach by Wang et al. [10] used a Bayesian approach to online learning based on logistic regression. High-level privacy preserving was ensured by encrypted posterior distribution of coefficients during the exchange between the server and the client. Additionally, the proposed model supports asynchronous communication between hospitals and allows dynamic model updating – i.e. there is no need to rebuild the model for each new patient. However, the complexity of the proposed approach rises with the number of included hospitals and [10] only presents results with up to 8 hospitals contributing to the global logistic

regression model. Rider and Chawla [11] use probabilistic graphical models to facilitate transfer learning between distinct healthcare data sets by parameter sharing while simultaneously constructing a disease network for interpretation by domain experts. Their approach is primarily used to rank the patient disease risk for multiple diseases simultaneously. A recent study by Wiens et al. [12] presents a more empirical evaluation of a transfer-learning approach using data from multiple hospitals to enhance local hospital predictions. A large sample of 132,853 admissions from three hospitals was used to test different scenarios on sharing the data or using models built on data from a specific hospital to predict on data from other participating hospitals. Although the study does not address privacy directly, it offers interesting results demonstrating high performance gains when data from all hospitals can be used in the final prediction.

Our study utilizes a large dataset of hospital discharge data to propose a novel approach in distributed predictive modeling that allows asynchronous exchange of models in a peer-to-peer or centralized environment. The proposed predictive model consists of two levels and is based on deep learning architectures [13, 14] that originate from a stacked generalization approach [15]. It was evaluated using data from 54 hospitals in California to demonstrate the large-scale deployment possibilities of the proposed approach. Compared to similar frameworks, we allow an additional high-level interpretability of results to obtain additional hospital level information. In contrast to most related work our approach allows combinations of different predictive models.

Background

Beginning October 1, 2012 under section 3025 of the Affordable Care Act, hospital reimbursements became tied to performance relative to preventable 30-day Medicare hospital readmission rates compared with hospitals having similar predicted risk profiles. Initially, readmission rates are tracked for three specific adult diagnoses: acute myocardial infarction (MI), congestive heart failure (HF), and pneumonia (PN). This change in the structure of Medicare reimbursements places increasing importance on the ability of health care providers to identify predictors of 30-day hospital readmissions as well as to identify characteristics of individuals and providers associated with above-average levels of readmission risk. Under-performing hospitals will see reduction of up to 1% in Medicare base reimbursements for services related to all diagnostic-related groups (DRGs). In 2010, these targets would have placed half of all hospitals in the under-performing group.

There are now plans to expand this approach to consider pediatric populations and growing interest in considering the value of pediatric readmissions rates as hospital quality indicators [16-18]. Research on pediatric readmission rates suggests that a small number of cases account for a disproportionate number of hospital readmissions [19]. Similarly, wide hospital-level variation is also seen. Considering sickle-cell anemia readmissions in a sample of more than 12,000 hospitalizations of some 4,762 children from 33 hospitals, Sobota et al. [20] found that even after adjusting for individual-level characteristics such as age, treatment, and complications, there was 4.2-fold variation in readmission rates between hospitals. Considering only admissions for appendicitis, Rice-Townsend et al. [21] found 3.8-fold variation between hospitals in readmissions rates after adjusting for disease severity and insurance status. In a larger study including 568,845 all-cause admissions at 72 children's hospitals, Berry et al. [22] found 28.6% greater adjusted readmission rates in hospitals with high versus low readmission rates. Overall, these findings point to the importance of considering differences between hospitals.

Despite considerable interest in this topic, the accuracy of predictive models for 30-day hospital readmission is not particularly strong. Horwitz et al. [23], for example, found in-sample prediction by area under the curve (AUC) of 0.61, 0.63, and 0.61 for MI, HF, and PN, respectively using Medicare claims data. More recently, focusing only on MI readmissions, Krumholz et al. [24] used 2006 Medicare claims data to compare models relying on claims data versus the combination of claims data and medical record data. These authors found high agreement (r=.98), but their overall model had an AUC of just 0.63.

Methods

Combining outputs of different predictive models to improve the performance of classification has been widely addressed in the research literature for the past two decades. The simplest approach to combining predictions from different models is majority voting, also called bagging [25] when combined with bootstrap sampling from the training dataset. In cases where classifiers are built from disjoint sets of data, Ting and Witten [26] name the

approach "dagging." In the same paper they propose an approach called dag-stacking, where an additional model is built to combine the outputs of low-level models instead of majority voting.

Stacked generalization approach inspired many novel, so-called deep learning frameworks [13, 14]. This paper introduces a stacked generalization based classification approach, inspired by dag-stacking, with a few important modifications from the original implementation by Wolpert [15] and Ting and Witten [26]. As described above, stacked generalization was originally proposed to leverage different types of classifiers that are used on the lower level of the stacking framework using a high-level classifier. Our approach aims to combine different classifiers of the same type built on disjoint sets of data (i.e. each classifier is built on data from a specific hospital). Ting and Witten [27] already noticed that it is possible to improve the results of the originally proposed stacking framework by combining confidence levels in contrast to predicted class labels. In our case, we use predicted risk of readmission obtained from regularized logistic regression models to prepare a high-level dataset (Figure 1). Additionally, we use a high level classifier (i.e. sparse logistic regression) that allows us to interpret the results of the high level classifier.

Suppose we have K different clinical sites or hospitals, on each site k there are n_k patients characterized by a matrix $X_k = \left[x_1^k, x_2^k, \cdots, x^{k_{n_k}} \right]^T$. We construct a local model $f_k : R^d \rightarrow R$ at each site *k* such that $f_k(x_i^k)$ returns the probability of hospital readmission for the *i*th patient in the *k*th clinical site, *d* is the dimensionality of the patient feature vector. For example, in the case of logistic regression, it learns a linear decision function

$$f_k(x_i^k) = w_k^T x_i^k + b_k$$

by minimizing the following logistic loss

$$\ell_{org}^k(w_k, b_k) = \frac{1}{n} \sum_{i=1}^{n_k} \log\left[1 + \exp\left(-y_i^k \left(w_k^T x_i^k + b_k\right)\right)\right]$$

where $y_i^k \in \{0,1\}$ is the label of x_i^k, such that $y_i^k = 1$ if the *i*th patient in the *k*th clinical site is re-admitted to hospital within 30 days, and $b_k \in R$ is the offset. The optimal solution of (w_k, b_k) by minimizing $\ell_{org}^k(w_k, b_k)$ can be obtained by iterative optimization methods such as gradient descent, Newtown method, or coordinate descent. For a detailed comparison of those methods one can refer to [28].

Generally there are many factors involved in every patient during the predictive modeling procedure, which makes *d* fairly large. In most of the cases only a small portion of factors would play important roles. It is highly desirable if the prediction model can also identify the set of important factors. Therefore Sparse Logistic Regression model is proposed, which aims to get the optimal (w_k, b_k) by minimizing the following objective

$$\ell_{sp}^k(w_k, b_k) = \frac{1}{n} \sum_{i=1}^{n_k} \log\left[1 + \exp\left(-y_i^k \left(w_k^T x_i^k + b_k\right)\right)\right] + \lambda \|w_k\|_1$$

where $\lambda > 0$ is the parameter trading off model sparsity and accuracy, and $\|\bullet\|_1$ is the vector ℓ_1 norm. The objective can be minimized by accelerated gradient descent as described in [29]. However, simple ℓ_1 regression has some limitations in small sample high dimensional case, as well as in the case when there are a group of highly correlated variables.

To overcome these limitations, Zou *et al.* [30] proposed elastic net regularization, which solves the optimal (w_k, b_k) by minimizing the following objective

$$\ell_{enet}^k(w_k, b_k) = \frac{1}{n} \sum_{i=1}^{n_k} \log\left[1 + \exp\left(-y_i^k \left(w_k^T x_i^k + b_k\right)\right)\right] + \lambda_1 \|w_k\|_1 + \lambda_2 \|w_k\|_2$$

where $\lambda_2 > 0$ is a regularization parameter and $\|\bullet\|_2$ is the ℓ_2 norm of a vector.

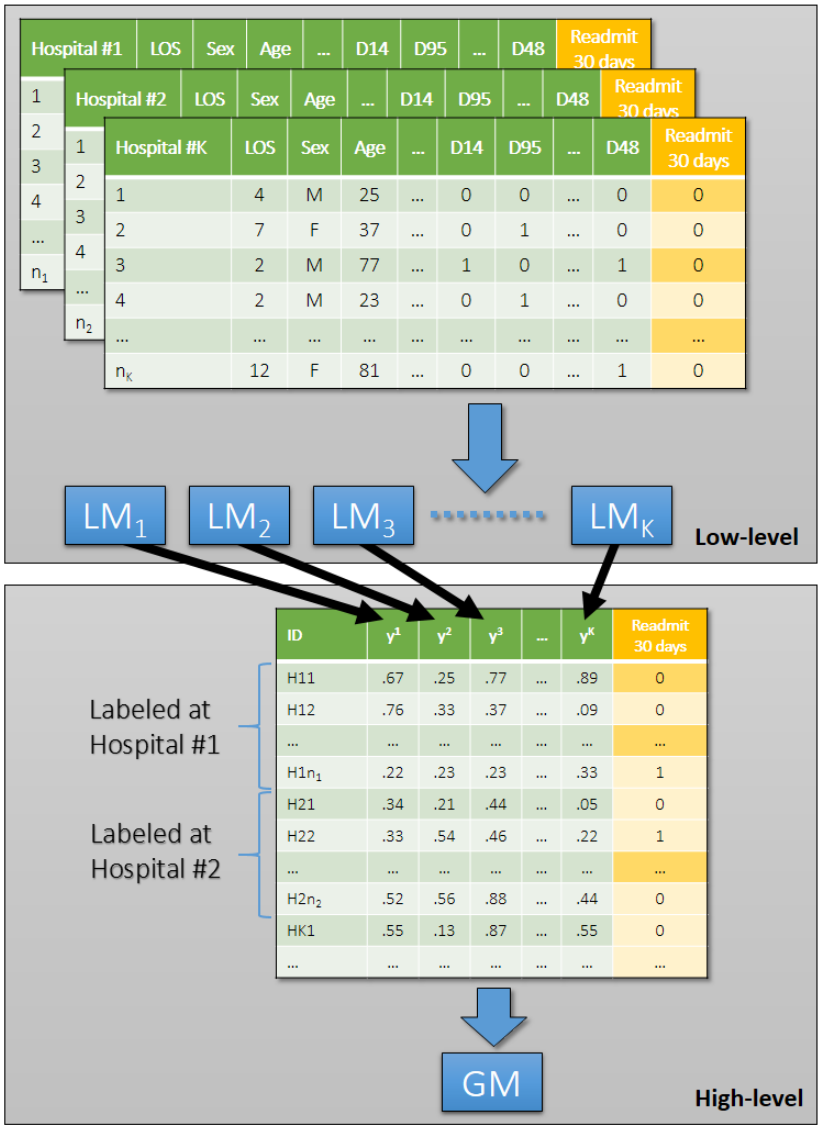

Figure 1. Two-level classification framework for distributed hospital based predictive modeling.

With this formulation, we can get the objective of original logistic regression with $\lambda_1 = \lambda_2 = 0$, sparse logistic regression with $\lambda_2 = 0$, and ridge logistic regression with $\lambda_1 = 0$. $\ell^k_{enet}(w_k, b_k)$ can be minimized by existing software packages such as *Glmnet* [31]. If (w_k^*, b_k^*) is the optimal solution, then the probability that the i^{th} patient in the k^{th} clinical site is re-admitted to hospital within 30 days can be computed as

$$p(y_k^i = 1 \mid x_k^i) = \frac{1}{1 + \exp\left[-(w_k^T x_k^i + b_k)\right]}$$

After we got the optimal prediction model $f_k^*(1 \le k \le K)$ for each site *k*, we collect all those models and form a set

$$F^* = \left\{ f_1^*, f_2^*, \cdots, f_K^* \right\}$$

Those models will be used as the low-level models. Then for each patient vector $x \in R^d$, we can form a *K*-dimensional vector

$$F^*(x) = \left[f_1^*(x), f_2^*(x), \cdots, f_K^*(x) \right]^T$$

We can train another prediction model $g : R^K \to R$ on those *K*-dimensional vectors, which will be used as the decision function on the higher level. Finally, we stack *F* and *g* together to make a classification decision.

Results

This section introduces the experimental settings of all experiments, followed by experimental results and interpretation of the high-level model to demonstrate the effectiveness of the proposed approach.

Experimental Settings

Hospital discharge data from California, State Inpatient Databases (SID), Healthcare Cost and Utilization Project (HCUP), Agency for Healthcare Research and Quality [32] was used in all experiments. The SID is a component of the HCUP, a partnership between federal and state governments and industry, tracking all hospital admissions at the individual level. We used all data from January 2009 through December 2011 in the pre-processing phase. Pediatric patients up to 10 years of age were used in this study due to specific regulations that allow age reporting in months instead of years only for patients younger than 132 months. Patients were excluded from the analysis if they died prior to discharge, were discharged on the same day as admission, were transferred to another institution, or were missing data on the unique patient identifier, age or sex. After pre-processing, we obtained the final dataset containing 66,994 discharge records with 11,184 positive (readmitted within 30 days) and 55,810 negative records.

The bottom 80% of all ICD-9-CM diagnosis codes, ranked by observed frequency, were removed from the dataset, leaving the top 122 diagnosis codes as binary diagnosis features. An additional 21 features (e.g., sex, age, month of admission, length of stay, total charges in USD, etc.) were also included (Table 1). Log transformed values for three numerical features (age, length of stay and total charges in USD) were also included. By recoding nominal features to binary values, we obtained 185 features that were used to build the models presented below.

Each experimental run included randomized training and test dataset where 2/3 of samples were used for training and 1/3 for testing. The holdout testing could cause extremely low number of positive cases in smaller hospitals. Therefore, we removed all records belonging to hospitals with less than 150 records. After removal of records from smaller hospitals, we obtained a final dataset with 61,111 records (10,675 positive and 50,436 negative). Due to a large number non-pediatric hospitals, only 54 out of the initial 205 hospitals were retained for the experiments. The test dataset was not used at all during the process of stacking or model development.

Classification Performance

To evaluate the performance of the built classifiers, we used Area under ROC Curve (AUC) metric. Holdout testing was repeated 1000 times to obtain more robust comparison of the AUC scores. In each run, we calculated the results for the following classification approaches:

- Best performing local model (BLM),
- Simple averaging of the local model outputs (AVG),
- Two-level deep learning architecture (DLA),
- Advanced two-level deep learning architecture with two different local models per hospital - i.e. elastic net and generalized boosted regression models [33] (DLA2) and

- Global sparse logistic regression model (elastic net) built on data from all hospitals. Figure 2 presents the distribution of AUC results for the three compared approaches (SLRA).

It can be observed that plain deep learning approach (AUC=0.781, 95% CI: 0.773-0.789) with a single elastic net classifier on hospital level does not significantly outperform a simple averaging approach (AUC=0.762, 95% CI: 0.746-0.775). However, it does perform much better on average. The proposed approach is also better in comparison to the best performing model from a single hospital (AUC=0.768, 95% CI: 0.758-0.777). We also observed the performance of the weakest local classifiers with an average AUC of 0.416 (95% CI: 0.355-0.481). These results point out that there are hospitals with models that cannot be used for practical application and would gain significantly if they can evaluate the risk for their patients with the proposed approach. When we added an additional, conceptually different model (i.e. generalized boosted models), for each hospital, in DLA2 (AUC=0.787, 95% CI: 0.780-0.794) we were able to significantly outperform AVG and BLM.

We were also interested in how much performance is lost when we compare our approach to a global model that would use all available data (simulating a scenario with no data exchange restrictions between hospitals). It turns out that neither DLA nor DLA2 significantly differ in terms of AUC performance when compared to single elastic net model built on all available data (AUC=0.789, 95% CI:0.781-0.796). On the other hand, both DLA2 and SLRA significantly outperformed averaged and best single models from hospitals.

Table 1. List of 143 features used for building and testing the proposed predictive models.

Feature name	Description	Feature name	Description
DSHOSPID	Unique hospital identifier	PAY1	Primary payer
TOTCHG	Total charge in USD	MEDINCSTQ	Quartile classification of the patient's estimated median household income
AGEMONTH	Age in months (12 - 131)	ASCHED	Scheduled hospitalization
LOS	Length of stay in days	PL_UR_CAT4	Four category urban-rural designation for the patient's county of residence
TOTCHG_LOG	Log transformed total charge in USD	Race	Race and ethnicity (White, Black, Hispanic, Asian or Pacific Islander, Native American, Other)
NPR	Number of procedures on hospital discharge record	MDC	Major Diagnostic Category
NCHRONIC	Number of chronic conditions	ORPROC	Operating room procedures
LOS_LOG	Log transformed length of stay	NECODE	Number of ICD9 E codes
ASOURCE	Source of admission	TRAN_IN	Type of admission
HCUP_ED	Presence of emergency department codes	HospitalUnit	Six hospital unit categories
FEMALE	Identification of gender	D1 – D122	Binary variables for presence of the most frequent diagnoses

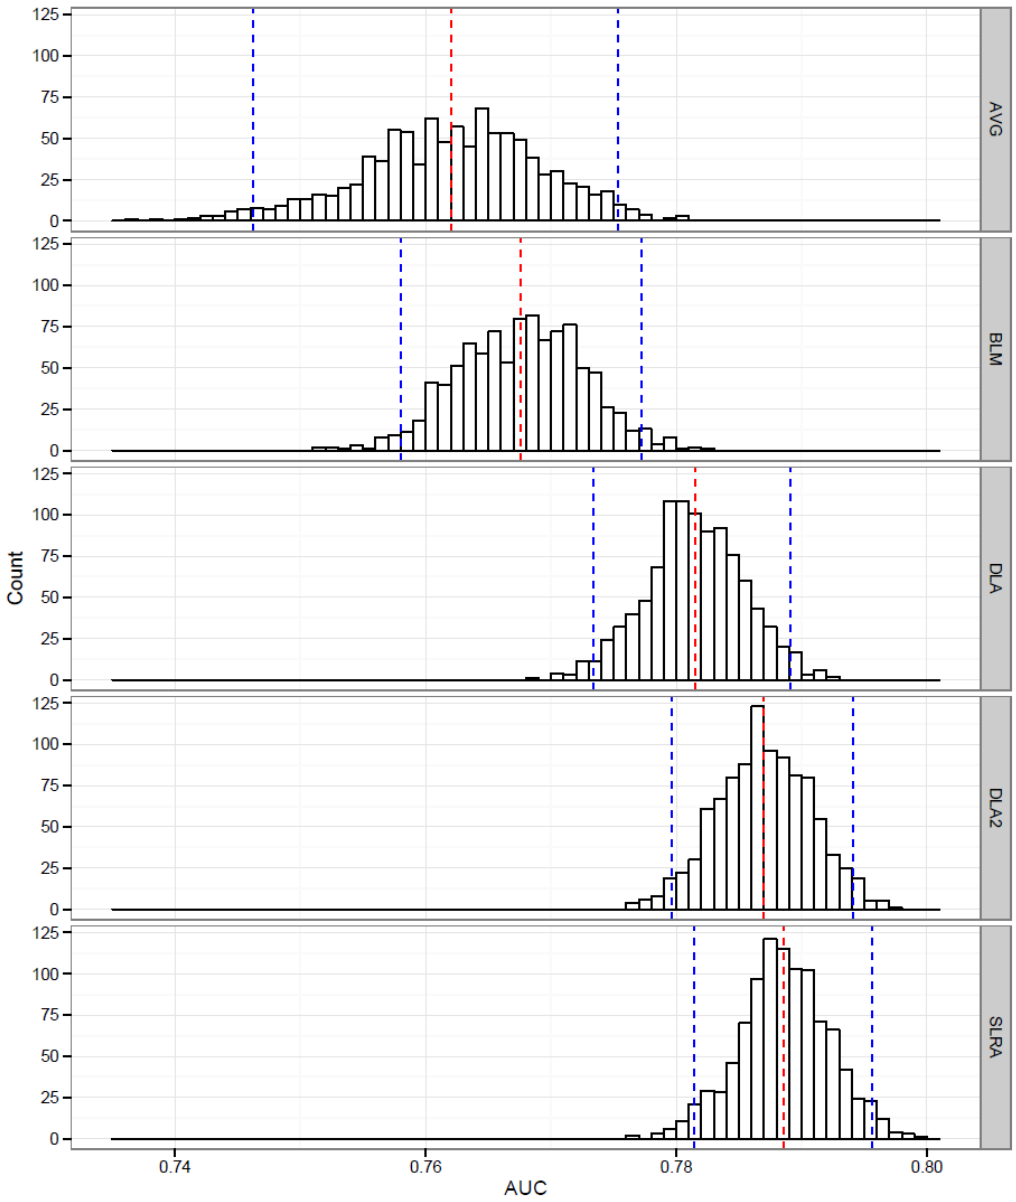

Figure 2. Distribution of AUC results on 1000 hold-out runs for averaged local models (AVG), best local model (BLM), deep learning approach (DLA), deep learning approach with two classifiers (DLA2) and single sparse logistic regression on all samples (SLRA) with mean AUC (red dotted line) and 95% CI (blue dotted line).

Interpretation of the High-level Classifier Results

In contrast to proposed approaches in distributed learning for medical applications [8-12], our approach additionally allows healthcare experts to interpret the results of the high-level classifier. The only constraint is the comprehensibility of the high-level classifier. In case of sparse logistic regression, we can obtain important information on inclusion of the local hospital models in the global model. Nevertheless, this is not the only information we can obtain – one can observe the relative influence of the specific local models in the global solution. For further interpretation of the global regression model, we calculated relative influence of all 54 local models based on their inclusion in the global model in 1000 holdout runs. Relative Hospital Influence (RHI) was calculated as a percentage of holdout runs when the specific hospital was included in the high-level sparse logistic

regression model (i.e. hospital's coefficient was non-zero). Table 2 demonstrates high level of heterogeneity among hospitals.

Table 1. Descriptive overview for 54 hospitals included in the study.

	Min	Max	Median	Mean	SD
Number of records	151	7,884	346.5	1,130.82	1,747.32
Average length of stay	1.90	12.68	3.42	3.95	1.79
Average number of chronic diseases	0.32	3.88	1.50	1.60	0.85
Average total charge (in USD)*	6,615	123,700	32,410	38,230	28,333
Average age of children (in months)	34.76	115.50	55.56	56.97	16.12

*12 hospitals with missing total charge data were excluded

Figure 3 presents correlation of RHI with the most interesting patient characteristics averaged for each of 54 hospitals that were selected based on their increasing or decreasing temporal trend. It can be observed that hospitals with higher cost per patient (TOTCHG) on average contribute more influential models to the final solution. There could be multiple reasons for correlation of influence and cost per patient (larger sample size in such hospitals, specialization of hospitals treating complex conditions, etc.). Therefore, some further analysis would be needed to explain this correlation. Likewise, average number of procedures on patient's discharge records correlates with RHI. This correlation is not difficult to explain as more procedures on the discharge records also means more details for the classification algorithm that can be used. Another positive correlation – i.e. with the average percentage of scheduled patients can be observed in the left lower chart of Figure 3. One should conduct further research into characteristics of hospitals where a large proportion of admission are scheduled to explain this correlation. The only negative correlation presented is the one relating RHI with percentage of children with pneumonia. It turns out that the high-level classifier rarely used outputs from hospitals with lower percentage of pneumonia. It is known from previous studies [34] that prediction of 30-day readmission represents a difficult problem with AUC performance of 0.63. Therefore, it might be possible that models from hospitals with high percentage of pneumonia perform relatively weak and are therefore rarely selected for inclusion in the final model. Readmission rates for hospitals also correlate with the RHI, pointing out that models built on data with stronger class imbalance will have a lower probability of inclusion. The last chart in lower right corner of Figure 3 presents another positive correlation between percentage of patients with gastrostomy (one of the most prevalent diagnoses in the observed population) and RHI. Berry et al. [22] found a similar relation in a study on recurrent readmission within children hospitals, where they confirmed a correlation between readmission frequency and the percentage of technology assistance. The most prevalent technologies among the patients with four or more readmissions were digestive related (30.7%), including gastrostomy tube.

Conclusions

In this study, we present a novel approach to distributed predictive modeling with application to 30-day all-cause readmission in children hospitals. Our approach is based on stacked generalization, dag-stacking and recently proposed deep-learning architectures. Using the proposed approach it is possible to significantly outperform a simple averaging as well as the best performing models from single hospitals. The results demonstrate that there is no significant difference in terms of AUC performance between the global model where data from all hospitals can be used and our approach to distributed predictive modeling. Additionally, our proposed models can be interpreted on high-level, offering an additional insight into the characteristics of specific hospitals. As such, the additional information can be used on policy-making levels to observe hospital quality on a more global level.

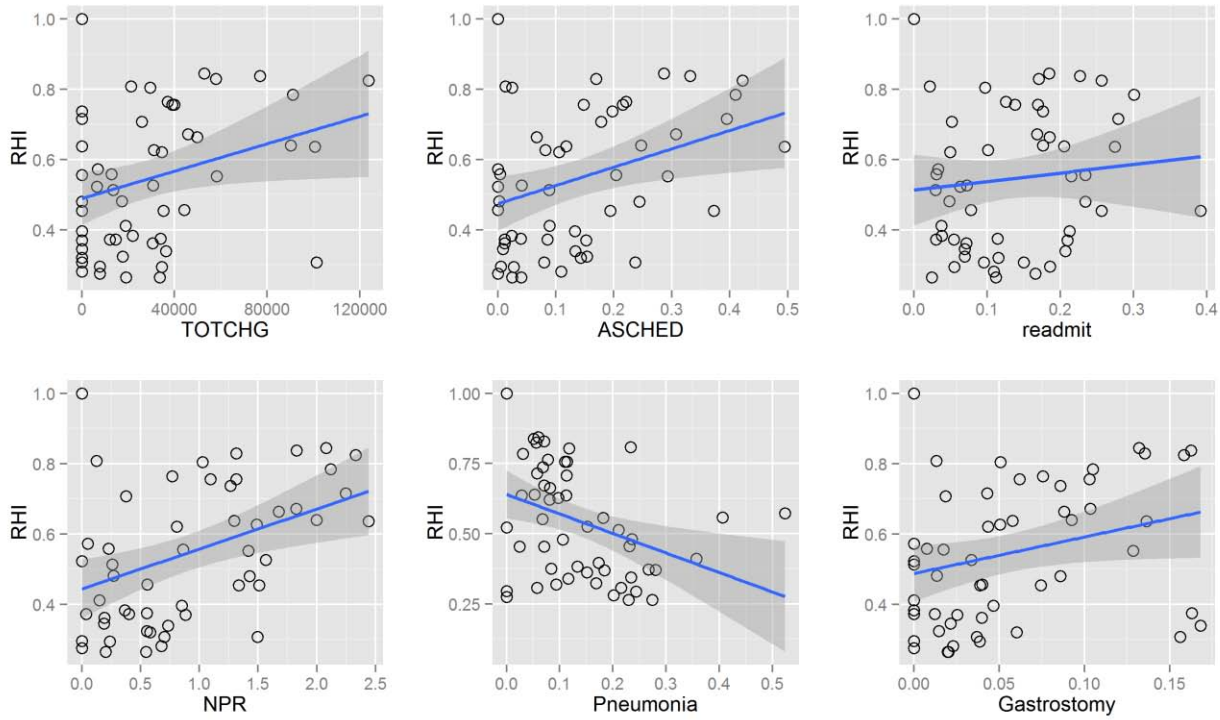

Figure 3. Trends of Relative Hospital Influence (RHI) in relation to average total charge per hospital (TOTCHG), percentage of records with diagnosed pneumonia (Pneumonia), average number of procedure codes on the record (NPR), rate of 30-day readmissions (readmit), percentage of scheduled admissions (ASCHED) and percentage of records with gastrostomy (Gastrostomy).

Text Classification towards Detecting Misdiagnosis of an Epilepsy Syndrome in a Pediatric Population

Ryan Sullivan, MS[1], Robert Yao[1], Randa Jarrar, MD[2]
Jeffrey Buchhalter, MD[3], PhD, Graciela Gonzalez, PhD[1]

[3]Alberta Childrens Hospital, Alberta, Canada

Abstract

When attempting to identify a specific epilepsy syndrome, physicians are often unable to make or agree upon a diagnosis. This is further complicated by the fact that the current classification and diagnosis of epilepsy requires specialized training and the use of resources not typically available to the average clinician, such as training to recognize specific seizure types and electroencephalography (EEG)[1–4]. Even when training and resources are available, expert epileptologists often find it challenging to identify seizure types and to distinguish between specific epilepsy syndromes[5]. Information relevant to the diagnosis is present in narrative form in the medical record across several visits for an individual patient. Our ultimate goal is to create a system that will assist physicians in the diagnosis of epilepsy. This paper explores, as a baseline, text classification methods that attempt to correlate the narrative text features to the diagnosis of West syndrome (Infantile Spasms), using data from Phoenix Children's Hospital (PCH). We tested these methods against a dataset containing known (coded) diagnosis of West Syndrome, and found the best performing method to have a precision / recall / f-measure of 76.8 / 66.7 / 71.4 when evaluated with 10-fold cross validation.

Introduction

Epilepsy and misidentification of specific epileptic syndromes has negative implications to public health. Epilepsy affects children and older adults, with 1 in 26 people suffering from it at some point in their lifetime, and about 65 million people affected world-wide[6]. In the U.S., epilepsy is the fourth most common neurologic disorder with a prevalence of 2.2 million and an incidence rate of 150,000 individuals annually. Epilepsy is often poorly managed, and misdiagnosed and untreated in the worst cases[1,6,7]. These epileptic patients may experience difficulties with independent living that includes difficulties in school, uncertainties about employment possibilities, and limitations on driving. About 1 in 10,000 newly diagnosed patients suffer sudden unexpected death in epilepsy[6]. While seizures, epilepsy, and their sequelae have always been present, there have been recent advances in the knowledge and understanding of the disease, its management, and its treatment. Unfortunately, current diagnostic and treatment methods do not adequately capitalize on these advances and patients who could be helped continue to suffer needlessly.

Epilepsy is a complex neurological disorder that manifests as two or more unprovoked seizures of varying types occurring within a 24-hour period[2,8]. An epileptic seizure, also known as an ictal event, is a transient occurrence of signs and/or symptoms that are the manifestations of abnormally excessive synchronous activity of a set of neurons in the brain[7 9,10]. A specific epilepsy syndrome is characterized by a cluster of signs and symptoms that define a unique epilepsy condition and often includes various seizure types[9–12]. To make the diagnosis of epilepsy, clinicians currently utilize the 1981 and 1989 International League Against Epilepsy (ILAE) classifications and clinical case experience. The identification of a specific epileptic syndrome begins with a description of symptoms by the patient and signs by eyewitnesses and requires the inclusion of electroencephalographic recordings of the ictal events. Depending on the type of seizures a person is suffering, along with other diagnostic measures such as age, developmental history, and EEG data, different types of epilepsy syndromes can be diagnosed, each of which requires different treatments. Unfortunately, few clinicians receive the training of expert epileptologists and epilepsy remains unidentified or misdiagnosed in as many as 12 to 23% of all cases leading to a mismatch of epilepsy syndrome to appropriate treatment and management[13].

Concern over epilepsy misdiagnosis has reached a tipping point in recent years, leading to the Institute of Medicine

(IOM) issuing the report, "Epilepsy Across the Spectrum"[6]. In the report, it was recognized that the inability of physicians to make or agree upon a diagnosis consistently for a specific epilepsy syndrome is the major cause of inadequate management of the disease, which in turn, has negatively impacted public health.

As a first step towards better methods for epilepsy syndrome identification, a retrospective analysis was conducted of 27524 patient records referred to Phoenix Children's Hospital (PCH). The objective of this study is to evaluate text classification methods that do not require any additional annotations, and that can correlate the narrative text present in the records (including EEG reports) to a specific diagnosis (West Syndrome).

Background

West Syndrome, also known as infantile spasms was one of the first epilepsy syndromes discovered. It has an incidence rate of 2 to 3.5 per 10,000 live births with 90% of cases occurring in the first year[14]. The diagnosis can be made based on age, developmental history, semiology (observed signs), and EEG patterns. Spasms typically have a neonatal onset and affect boys slightly more than girls between 4 to 8 months of age, but occasionally late onset may occur[15]. Additionally, the child typically has marked developmental delay and mental retardation[14]. Semiologically, a cluster of motor seizures of two major types (spasms and tonic contractions) occur for a duration of less than 1-10 minutes[14,15]. The initial component consists of 2-100 brief epileptic spasms of variable frequency of 1-2 seconds for each spasm[14,15]. These affect primarily the axial muscles of the neck and trunk and appear as characteristic head noddings or "bobbings"[15]. As these seizures occur, various characteristic features on an EEG can be observed. These observations are typically described in detail within the narrative portions of the record and the EEG report.

The clinical features of infantile spasms are considered characteristic, and a diagnosis can be easily made by an expert epileptologist. It is one of the least misdiagnosed epilepsy syndromes, and is thus an excellent case study for the methods proposed, as we expect that most of the true positives will be correctly coded for West Syndrome in the PCH dataset. Still, manual review of false positives is ongoing.

However, it is possible that if certain features co-occur, there may be cases of West Syndrome that may have been missed in the original assessment, and there might be cases that require only one or two additional pieces of information to clinch the diagnosis. An automatic method that could notify the tending physician at the right time could help identify such cases.

Natural Language Processing based Clinical Decision Support has been discussed in Demner-Fushman et al., however Meystre et al. suggest that this area of research is relatively underdeveloped compared to other areas of BioNLP[16,17]. However, there do exist a few similar systems. Yetisgen-Yildiz et al. present a system for the identification of patients with acute lung injury from free-text chest x-ray reports[18]. This system uses a feature set based on unigrams, bigrams and trigrams as well as an assertion analysis system to classify the free-text of x-ray reports. Their best performing classifier configuration achieved a precision / recall / f-measure score of 81.70% / 75.59 % / 74.61 %.

Another system developed by Wagholikar et al. uses NLP techniques to generate cervical cancer screening guidelines from free-text Pap reports[19]. This system used hand-crafted rules to suggest cervical cancer screenings based on the text of the Pap reports, and in their evaluation they found that their system suggested the optimal screening recommendations in 73 of their 74 test cases.

A very similar area of research that has been more supported by the BioNLP community is the automatic coding of medical text. This field of study was the subject of a shared task, which challenged teams to automatically assign ICD-9-CM codes to radiology reports[20]. While a number of the top performing systems in the challenge rely on experts to manually craft rules for their systems, Farkas and Szarvas present that uses machine learning techniques to automatically generate coding rules for their system[21]. Their resulting system achieved a precision / recall / f-measure score of 87.85% / 90.04 % / 88.93 % on the shared task test set, whereas the highest scoring system from the challenged achieved an f-measure of 89.08 %.

Methods

Dataset: A retrospective analysis was conducted of 27524 patient records referred to Phoenix Children's Hospital (PCH). These records consist of patients that have been coded for epilepsy (all ICD9 345 codes) as well as those

with insufficient clinical evidence to support a specific diagnosis of an epilepsy syndrome (patients coded with ICD9 780.39 'Other Convulsions'). We divided the patient records into three groups: 1) 144 patients coded for Infantile Spasms (ICD9 codes 345.60 and 345.61); 2) 2818 patients with records that contain Infantile Spasm-related keywords ["infantile spasms", "tuberous sclerosis", "hypsarrythmia", "ACTH", "prednisolone" and "aicardi syndrome"], but are not coded for Infantile Spasms; and 3) 27524 patients with records neither coded for infantile spasms nor containing Infantile Spasm-related keywords. For our experiments, we created a corpus consisting of the records of the 144 patients coded for infantile spasms as positive examples and the records of 3600 randomly chosen patients from group three as negative examples.

Preprocessing: For this classification task, we only used the free-text from discharge summaries and EEG reports. We used a simple tokenizer to tokenized the text at whitespace and punctuation, and removed all digits and special characters. We also removed all Infantile Spasm-related keywords and English stopwords from the text.

Feature generation: We tested two different techniques for generating a feature set from the patient record free-text, TF-IDF vectors and a topic distribution based on Latent Dirichlet Allocation (LDA).

Our first feature set consisted of TF-IDF (term frequency-inverse document frequency) vectors, a popular scheme that is generally used for indexing documents for information retrieval[22]. For each term in a document, the term frequency (how many time a term appears in the document) and the inverse document frequency (a measure of how rare a term is across documents) is calculated, and these values are used to construct a term vector representation of the document.

Our second approach consisted of representing each patient as a topic distribution based on Latent Dirichlet Allocation (LDA)[23]. LDA is an unsupervised technique used for topic discovery and text classification. It assumes that each document is generated based on some topic distribution and each topic's word distribution. It then attempts to use the observed information, i.e. the words in the documents, to predict the unobserved information, i.e. the topics, the topic distribution and the word distributions within each topic. We learned an LDA topic model on the patient data consisting of 1500 topics, with the topic size chosen based on testing a subsample of the corpus, and we used the corpus to estimate the topic distribution for each record. We used the Mallet toolkit to build the LDA models[24] We used this topic distribution as a feature set, in a method that tantamount to using LDA for dimensionality reduction and is mentioned in Blei and McAuliffe[25].

Training data sampling: One issue we encountered with the dataset is the relative rarity of Infantile Spasm patients compared to the negative examples. Because of this disparity, we ran into issues of having too few positive examples to train our classifiers.

We tested two solutions to this problem, oversampling the positive classes and undersampling the negative classes. In both cases, we attempted to have a 3 to 1 ratio of negative to positive examples (compared to the 25 to 1 ratio of our corpus). In oversampling, we keep the number of negative examples the same, but give the positive examples a weight of 8.33 times the negative examples. In undersampling, we trained the model on a random subset of the data which has the 3 to 1 ratio.

Classification and Evaluation We compared two different classification algorithms for this task; a multinomial Naïve Bayes classifier and a Support Vector Machine classifier[26,27]. These classifiers were chosen for their speed and for their documented performance in text classification tasks.

We evaluated our classification models using 10-fold cross validation, and we trained and evaluated each classification model using Weka[28].

Results and Discussion

The results of our experiment can be seen in Table 1.

These results do not overtake the top performing systems, yet they are compatible to other systems in this domain, and they represent a reasonable baseline for which to continue research. Furthermore, these results show that the use of domain knowledge is not a necessary requirement to achieve reasonable results. There are also a few conclusions that can be drawn from these results. The first conclusion is that a sampling method (either over or under sampling) is a

Table 1: Classification results.

Classifier	*Precision*	*Recall*	*F-Measure*
multinomial Naïve Bayes - LDA - no sampling	16.5%	61.8%	26.1%
multinomial Naïve Bayes - TF*IDF - no sampling	19.4%	53.5%	28.5%
SVM - LDA - no sampling	45.0%	34.7%	39.2%
SVM - TF*IDF - no sampling	55.1%	29.9%	38.7%
multinomial Naïve Bayes - LDA - oversampling	47.4%	75.7%	58.3%
multinomial Naïve Bayes - TF*IDF - oversampling	77.5%	55.6%	64.7%
SVM - LDA - oversampling	81.4%	29.9%	43.7%
SVM - TF*IDF - oversampling	88.2%	29.9%	44.6%
multinomial Naïve Bayes - LDA - undersampling	50.0%	70.8%	58.6%
multinomial Naïve Bayes - TF*IDF - undersampling	59.7%	75.0%	66.5%
SVM - LDA - undersampling	70.1%	65.3%	67.6%
SVM - TF*IDF - undersampling	76.8%	66.7%	71.4%

requirement to get usable performance. However, from analyzing the results, it seems that oversampling may be over fitting the data, which causes the precision-recall difference between the over and under sampling.

We can also gather from these results that LDA is an effective dimension reduction technique for this type of text, when using a SVM classifier. Though the TF-IDF features outperform the LDA-based features, the TF-IDF vectors are 10 times as large, and represent a non-trivial computation time cost for certain classifiers. Finally, we can see that SVM consistently had high precision-low recall compared to the Naïve Bayes' comparatively low precision-high recall. Though one would ideally want both high precision and high recall, these classifier tendencies are worth keeping in mind depending on the task.

Conclusion

The use of Natural Language Processing for Clinical Decision Support is an academically underserved domain that holds a large potential. The results of our baseline system are comparable to other systems in the domain, and can identify misdiagnosed epilepsies or improve the ability for medical doctors to identify an epilepsy syndrome not previously diagnosed. This can potentially improve the match between patient and the best treatment available for a specific epilepsy syndrome, and can further the goal for better seizure control and improvement in quality of life for the patient.

Adding flexible temporal constraints to identify chronic comorbid conditions in ambulatory claims data

Walton Sumner, MD[1], Dustin L Stwalley, MA[1], Phillip V. Asaro, MD[1], Michael D. Hagen, MD[2], Margaret A Olsen, PhD, MPH[1]

[1]Washington University School of Medicine, St. Louis, MO;
[2]American Board of Family Medicine, Lexington, KY

Abstract

Chronic comorbid conditions are important predictors of primary care outcomes, provide context for clinical decisions, and are potential complications of diseases and treatments. Comorbidity indices and multimorbidity categorization strategies based on administrative claims data enumerate diagnostic codes in easily modifiable lists, but usually have inflexible temporal requirements, such as requiring two claims greater than 30 days apart, or three claims in three quarters. Table structures and claims data search algorithms were developed to support flexible temporal constraints. Tables of disease categories allow subgroups with different numbers of events, different times between similar claims, variable periods of interest, and specified diagnostic code substitutability. The strategy was tested on five years of private insurance claims from 2.2 million working age adults. The contrast between rarely recorded, high prevalence diagnoses (smoking and obesity) and frequently recorded but not necessarily chronic diagnoses (musculoskeletal complaints) demonstrated the advantage of flexible temporal criteria.

Introduction

Comorbid conditions are extremely important predictors of primary care outcomes[1-3]. In addition, comorbid conditions may complicate disease management, and may even result from disease management.

Comorbidity indices merge numerous clinical observations into a single score that predicts an outcome. The Charlson score, published in 1994, predicted mortality in patients undergoing elective surgery based on 19 categories of comorbid conditions[4]. The Elixhauser comorbidity index, published in 1998, defines 30 categories of comorbid conditions for use with administrative claims data[5]. These categories comprise sets of diagnosis codes from the International Classification of Diseases, version 9, Clinical Modification (ICD-9-CM). The Elixhauser index predicts mortality, charges, and length of a hospitalization. Klabunde, et al described in 2000 how outpatient records could identify comorbid conditions that were undocumented during hospitalization[6] but that would affect hospital outcomes[7].

While comorbidity indices simplify predictive analyses, the complexity of comorbidity, often called multimorbidity, is more relevant to many clinical decisions. Analysis of multimorbidity requires that thousands of very specific diagnostic codes be mapped into scores or hundreds of categories of conditions. Several reports describe categorization strategies for common comorbid conditions in claims data[8-10]. Even crude measures of multimorbidity, e.g. counts of comorbid conditions, are consistently predictive of outcomes.

Several issues distinguish the identification of comorbidities from ambulatory vs. hospital claims data. First, omissions are common in ambulatory claims. Outpatient claims headings in the USA are restricted to 4 diagnostic codes, although "line codes" may include an additional diagnostic code for each procedure claimed. Inpatient claims headings currently are restricted to 25 diagnostic codes for Medicare claims, but have been as few as 9 codes in the past. Furthermore, diagnoses such as smoking and obesity may be absent for years in outpatient claims, but then be recorded when patients have elective surgery. Undocumented diagnoses may appear to (i) be tangential or subordinate to acute problems, (ii) lack effective treatments, leading to lack of attention, (iii) lack documentation incentives, such as reimbursement or quality measures, (iv) carry a risk of stigmatizing patients, or (v) carry a risk of causing a confrontation when patients see the code descriptions on billing records. Thus, inpatient claims from one hospitalization provide a more complete picture than office claims from one visit. Practical limits on numbers of claims imply that (a) any short series of outpatient visits can fail to document relevant comorbidities and (b) diagnoses that are often missed, neglected, or ignored could appear infrequently in claims. For these reasons, long periods of surveillance may be appropriate.

Second, an outpatient claim does not indicate a definite diagnosis. One problem is that clinicians may record codes for diagnoses being ruled out. Another issue is that clinicians often select codes with little direction and only delayed feedback through reimbursement. Professional coders assign inpatient claims, following guidelines that should

increase the odds that the diagnosis is present. Thus, inpatient claims could be more accurate than office claims, although both may be biased toward codes yielding higher reimbursement[11-13]. Finally, diagnostic conclusions can be wrong[14-16]. When diagnostic errors are discovered, the incorrect diagnosis should disappear from the record. Ambulatory claims analyses therefore require some strategy for establishing validity of outpatient claims. One rule of thumb requires a diagnosis to appear twice, more than 30 days apart, to infer that an outpatient diagnosis is real[17]. A more stringent German algorithm required a diagnosis to appear once each quarter (3 months) for 3 consecutive quarters[10]. Of course, some chronic diseases can actually resolve, especially those related to weight, diet, substance abuse, and other reversible problems. The three preceding quarters defines a moving window that eventually removes incorrect and resolved diagnoses.

Third, some broad comorbidity categories used to predict hospital mortality warrant dissection for primary care quality and outcomes analyses. Distinctions between organ impairment and failure are important for renal and hepatic diseases. Patients with injured organs need their physicians to help them minimize the rate at which further injury accumulates, while patients with overt organ failure often face different risks. For instance, the risk of cardiovascular disease initially rises slowly as renal function deteriorates but becomes extreme as kidneys finally fail[18, 19]. Hospital mortality-oriented comorbidity classifications may combine diverse, common neurologic diseases that primary care analyses should subdivide, such as dementia, headaches, seizures, and stroke.

Fourth, many conditions could influence treatments, costs, and outcomes in primary care, or result from medical treatment, without affecting hospital mortality. Topics of primary care include allergies, anxiety, esophageal reflux, migraine and tension headaches, chronic musculoskeletal problems, osteoporosis, smoking, and personality disorders. For instance, osteoporosis may have important outpatient implications (such as increasing the risk of using of corticosteroids) without affecting hospital mortality. Conversely, diagnoses with dire implications for hospital mortality may be unmanageable in the outpatient context.

In order to analyze outpatient claims data describing family physicians' management of specific diseases, we needed to classify patients' comorbid conditions. Due to the issues just enumerated and other experiences with outpatient claims, we believed that the inference of comorbid conditions from outpatient data could be further refined. We particularly wanted to increase the temporal flexibility of comorbidity definitions in response to common documentation patterns. We report the development and testing of a chronic disease list with temporal criteria for analyzing outpatient claims data.

Methods

Categories of diagnosis codes

The Elixhauser [5] and German ambulatory care [10] lists of comorbid conditions were reviewed by category. Categories that included common problems with very diverse clinical implications were subdivided into categories with more uniform implications. Categories that were unlikely to occur in primary care were deleted, and categories for common and clinically influential problems were added. ICD-9-CM diagnosis codes were sought using the hierarchical structure of ICD, and by searching for specific codes and string values.

We determined that assigning codes to a single comorbidity category still limited our ability to make higher resolution inferences that would be desirable in some analyses. We defined *subgroups* within categories, including a "subgroup zero" containing codes that could match any other subgroup within a category.

After defining subgroups, we noted that requiring repeated documentation of codes in a subgroup could lead to false positive matches unless mutually substitutable codes were specified. We therefore defined *bundles* of codes that we considered mutually substitutable. For instance, the musculoskeletal group has a subgroup for joint problems. Within the joint subgroup, there are several codes for arthritis of the shoulder and others for arthritis of the hip. The shoulder codes are mutually substitutable and belong to one bundle; the hip codes are in a different bundle. Again, a "bundle zero" identified very imprecise codes that could match any bundle in the subgroup, e.g. "arthritis, NOS."

Timing of claims

Flexible temporal constraints were added to subgroup definitions. First, we provided minimum numbers of outpatient events as a subgroup specification. Fixed requirements for at least two or at least three outpatient claims over a period were judged unlikely to work consistently. More or fewer claims could be appropriate. For diseases that are rarely documented at all and normally are recorded after being "ruled in," such as smoking, obesity, and personality disorders, one appearance in an outpatient claim suggests relevance for years before and after the claim. Conversely, an acute problem recurring many times over a few years could be considered a chronic problem.

Second, we added minimum separation between outpatient events as a subgroup specification. Any fixed temporal separation may be excessively or insufficiently restrictive for some condition. For instance, a patient presenting with angina could be evaluated and receive an effective medical intervention in less than 30 days. If chest pain resolves and other risk factors command attention at subsequent visits, angina codes could disappear from claims records. Nevertheless, the patient would have evidence of coronary artery disease as a comorbid condition. Clinical scenarios requiring longer minimum intervals are rare, but consider provoked and unprovoked venous thrombosis. Provoked venous thrombosis will generate a series of claims over 3 to 6 months. Clotting disorders will generate claims over longer intervals, due to recurrence of clots. Therefore, a minimum interval of 90, 180, or even 270 days between venous thromboembolic claims could be appropriate when attempting to infer a clotting disorder.

Third, we added a maximum separation between outpatient events as a subgroup specification. Most algorithms have not specified maximum separation between codes, but some maximum separation is often justifiable. Invasive breast cancer codes may appear annually in claims for women aged 40 to 60; this probably does not indicate an active neoplasm, but the intent of the diagnostic test (to identify preclinical breast cancer). Discovery of a new neoplasm should generate a series of claims at short intervals. At the other extreme, a seizure disorder documented at annual visits could indicate a stable patient receiving annual medication refills.

Finally, we added persistence, a time to look back through for the other requirements, as a subgroup specification. This change relaxes the fixed three quarters implemented in the German ambulatory care algorithm. In a long series of claims data, some potentially chronic diseases will remit: weight loss will cure some diabetics and abstinence will cure some alcoholics' hepatitis. However, if an incurable diagnosis disappears from the series, then the diagnosis is in question. For instance, Parkinson's disease is currently incurable and debilitating: it should appear regularly in a patient's claims. If the diagnosis was not recorded in the most recent two years, then any earlier diagnosis of Parkinsons' disease is doubtful.

Table structure

We implemented these constraints in two tables, subgroups and codes. The subgroup table has these fields, with each combination of Group and Subgroup being unique:

Group	positive integer identifier
Abbrev	short name for the group
Subgroup	non-negative integer identifier
Name	short name for the subgroup
IP Count	number of inpatient claims (within a bundle) required to establish the subgroup; zero if inpatient claims never establish the subgroup being present
OP Count	number of outpatient claims (within a bundle) required to establish the subgroup
MinSep	minimum number of days between claims (within a bundle)
MaxSep	maximum number of days between claims (within a bundle)
Persist	maximum number of days to look back from a specified date

The code table has these fields:

Key	a unique row number
Group	positive integer identifier
SubGroup	non-negative integer identifier
Bundle	non-negative integer identifier
Code	ICD9-CM code
Description	description of the ICD9-CM code

General approach to specifying groups and subgroups

Given the above considerations and the lack of standardization in assignment of diagnostic codes for outpatient billing claims, we found that subgroup specifications were quite subjective, especially in regard to time intervals. We therefore developed some general principles for assigning subgroups' attributes.

- Number of instances required
    - One inpatient code may establish a clearly chronic condition
    - Inpatient codes for potentially acute or iatrogenic conditions may be ignored, so that the condition must be established by outpatient codes
    - One outpatient code may establish a clearly chronic condition that is under-documented

- Two outpatient codes are needed to infer most chronic conditions
- More than two outpatient codes may be used to infer that a normally acute condition is functionally chronic

- Separation of outpatient codes
  - As a default setting, pairs of claims are at least 30 days apart and not more than 180 days apart
  - Acute events that imply chronic problems may have shorter minimum separation requirements (strokes ad heart attacks)
  - Chronic conditions that could be stabilized and managed with annual checks were set 400 days (13 months) apart (seizure disorders)
  - Infrequent events that imply chronic problems may be set farther apart (smoking, obesity), but in the USA, private claims data may not capture two infrequent events due to limited periods of enrollment (3 years on average)
- Time since last diagnosis (persist field)
  - Incurable, confidently diagnosed, and rarely recorded diseases may persist indefinitely (strokes)
  - Potentially curable chronic diseases should be confirmed by periodic reappearance (restless leg syndrome) or change to "history of" codes (neoplasms)
  - Inexorably progressive diseases should be confirmed by periodic reappearance (degenerative neurologic diseases)
  - Rarely recorded but curable diseases should be inferred from appearance over a long but not indefinite interval (smoking, obesity)

Algorithm

These definitions reflect the possibility of evolving comorbidity status in primary care analyses of claims data. In procedural pseudo code, the logic for interpreting these data is:

```
Establish assessment date D
Get individual's claims data
For each Group G in the subgroup table
    Put claims for Group G, Subgroup zero, Bundle zero into wild card Subgroup claims
    For each Subgroup S>0 in Group G
        Put claims for Group G, Subgroup S, Bundle zero into wild card Bundle claims
        For each Bundle B>0 in Group G, Subgroup S
            Put claims for Group G, Subgroup S, Bundle B into Bundle B claims
            Merge wild card Subgroup and Bundle into the Bundle B claims list
        If Group G, Subgroup S defines Persist>0 then
                Limit Bundle B claims list to dates between D - Persist and D
            End if
            If Group G, Subgroup S defines IPCount>0 then
                If number of Inpatient claims in Bundle B claims>IPCount then
                    Patient has comorbidity Group G
                    Patient has comorbidity Subgroup S
                    Next Subgroup
                End if
            End if
            For each claim in the claims list
                Put claim into Sequence Q
                For each subsequent claim in the claims list
                    Get days between last claim in Q and this subsequent claim
                    If days >= SepMin and days <= SepMax then
                        Add claim to sequence Q
                    End if
                    If number of claims in Q > OP count for Group G, Subgroup S then
                    Patient has comorbidity Group G
                        If at least one claim in Q is in Bundle B then
                            Patient has comorbidity Subgroup S
                            Next Subgroup
```

Trial

We implemented the search algorithm and applied it to five years of private insurance claims data from three states in the Truven Health Analytics MarketScan® Commercial Claims and Encounters Databases. Medical claims were restricted to (i) persons aged 18 to 64 years and (ii) claims with a specialty code for general internists or family physicians, thus excluding facility, laboratory, and other specialty claims. Comorbidity prevalence was calculated for each category and subgroup. Patient level prevalence over the five years was calculated for each ICD-9CM claim that was not categorized as a chronic comorbidity. These codes were reviewed manually to identify (a) codes that were included in the codes table but failed temporal criteria, (b) codes that should have been included in the codes table, and (c) codes that were reasonably excluded from the codes table. After reviewing results from the preliminary draft, some comorbid conditions were added and temporal criteria were modified for others. The search algorithm was refined to obtain the form described above and applied to the revised tables to obtain the ensuing results.

Results

Categories, subgroups and bundles

We defined 50 categories with 154 specific subgroups and 13 wild card subgroups. The 50 categories included 2,733 ICD9-CM codes in 367 bundles. The most commonly assigned temporal requirement was 2 claims 30 to 400 days apart, over the past 1 or more years (67 uses), followed by 2 claims 30 to 180 days apart, over the past 1 or more years (33 uses) and 2 claims 30 to 730 days apart, over the past 2 or more years (10 uses). Persistence was about equally divided between 1, 2, 3, 5, and indefinite time spans. Three subgroups required a single claim within 4 or 5 years. Six subgroups required three or more claims.

Test run results

The test run analyzed records of up to five years' duration from 2.2 million adult patients seen by family physicians and/or general internists between 2006 and 2012. The average duration of enrollment was 2.5 years.

Table 1 summarizes the frequency with which patients met criteria for the 50 categories, sorted from most to least frequent positive matches as a percentage of the 2.2 million patients. The number of subgroups and ICD codes specified in each category is given. The "Time Criteria Fails" column lists the percentage of patients who had one of the codes in the group documented, but a time criterion was not met. The largest of these, musculoskeletal diagnoses, involves 12% of patients. An extremely low number of patients were documented to be smokers (0.83%,) or obese or morbidly obese (1%). Two thirds of the smokers and half of the obese patients had exactly one claim with the diagnosis. In contrast, the population prevalence of smoking is 5% for individuals with graduate degrees [20], and above 20% for all workers [21], and obesity affects nearly 30% of the workforce[22].

Figure 1 plots time criteria failures (Table 1, Column 5) as a function of comorbidity prevalence (Table 1, Column 2) for each category. For instance, the outlier point at (2%, 12%) is the musculoskeletal category. The point indicates that 2% of patients have chronic musculoskeletal conditions, as defined here. Another 12% have diagnostic codes included in the musculoskeletal category, but did not meet specified time constraints. For instance, a person having two claims related to back injuries occurring less than 20 days apart would fail the temporal criteria (see table 2). Other musculoskeletal subgroups require more than two claims.

Table 2 summarizes the main subgroup's requirements in each category. Usually, the other subgroups in a category will have comparable constraints. The number of Inpatient (*IP*) and Outpatient (*OP*) events required is listed. Zero IP events means that only outpatient diagnoses are accepted. Zero OP events means that the subgroup is a wildcard. The *min*imum and *max*imum separation between events is listed, and the persistence of a diagnosis is listed in the *look back* column. The number of distinct ICD-9CM *codes* used and number of *bundles* in each main subgroup completes the table.

Claims that did not match categorization criteria involved 9,158 distinct ICD-9CM codes, of which 7,316 codes did not map to any of the 50 categories. The remaining 1,842 matched a code in a category, but were not in a series of claims that met temporal requirements. Table 3 lists the uncategorized codes affecting at least 0.5% of the 2.2 million people in the sample. Codes that are included in a comorbidity category are in bold italics.

Discussion

We present a refinement in strategies for defining comorbid conditions based on provider (outpatient) rather than facility (inpatient) claims. The disease categories presented here are familiar from previous work, especially by Charlson[4], Elixhauser[5], and van den Bussche[10]. We extended these systems by adding flexible temporal constraints, including the option to require any number of instances of a diagnosis in provider claims. The value of this flexibility in required numbers was evident in the test run. Smoking and obesity documentation is so sparse that less than 5% of cases are documented during the average 2.5 years of claims data, and half of the documented cases were based on only one claim. Requiring two or three claims to confirm these diagnoses would risk eliminating nearly all documentation of these fundamental problems. Conversely, six out of seven patients with musculoskeletal claims do not generate enough claims to be categorized as chronic conditions – these problems are usually of short duration.

In addition, we have explicitly described three levels of hierarchy, starting with 50 broad categories, followed by 154 specific subgroups. The subgroups have much more uniform primary care management implications than the categories. The diagnoses in many subgroups share similar pathology, treatment strategies, complication risks, and morbidity implications. The third level of the hierarchy consists of substitutable bundles of diagnoses within subgroups. Given the frequency of claims in some categories, such as musculoskeletal, false positive categorization would occur over time because of related processes occurring at unrelated sites unless the sites' (or processes') codes are grouped in substitutable sets.

These temporal definitions are quite flexible. Transient comorbidities could be defined. For instance, respiratory tract infections in the last 30 days could be specified as a transient comorbidity in a study of asthma. A respiratory infection is a transient risk factor for asthma exacerbations, but one that persists for only a few weeks: farther removed infections are usually irrelevant.

Limitations

The categorization outlined here may improve with the addition of treatment information or inferences based on other diagnostic claims. For instance, both smoking and obesity can be inferred from the appearance of associated diseases. Patients with mental health problems (smoking risk factor) and acute bronchitis (smoking consequence) are likely to smoke. Chronic obstructive pulmonary disease or lung cancer would make a history of smoking nearly certain. Obesity is likely when recent claims include knee osteoarthritis, gastroesophageal reflux, sleep apnea, hypertension and type II diabetes. Many other diseases and risk of death can be inferred from the presence of prescription claims[23, 24]. However, pharmacy claims analysis introduces new challenges. Paradoxical relationships between claims and outcomes have been attributed to "selective under-use of drugs by elderly patients" [25]. Increasingly popular "$4 drug list" prescriptions [26] are not captured in claims data. Anonymity as well as price may motivate use of these deeply discounted pharmacies [27]. Widespread use by insured patients will limit inferences based on prescription claims [28-30].

Another issue is that longitudinal surveillance identifies patterns of claims, which may have distinct implications for outcomes [31]. The use of temporal criteria to identify comorbid conditions risks obscuring this complexity if claims patterns are not considered in analyses.

Conclusions

Temporal constraints applied to ambulatory claims may improve comorbid condition categorization. Nevertheless, incomplete documentation of relevant conditions impedes complete description of primary care patients' multimorbidity.

Abstract

Data fragmentation within electronic health records causes gaps in the information readily available to clinicians. We investigated the information needs of emergency medicine clinicians in order to design an electronic dashboard to fill information gaps in the emergency department. An online survey was distributed to all emergency medicine physicians at a large, urban academic medical center. The survey response rate was 48% (52/109). The clinical information items reported to be most helpful while caring for patients in the emergency department were vital signs, electrocardiogram (ECG) reports, previous discharge summaries, and previous lab results. Brief structured interviews were also conducted with 18 clinicians during their shifts in the emergency department. From the interviews, three themes emerged: 1) difficulty accessing vital signs, 2) difficulty accessing point-of-care tests, and 3) difficulty comparing the current ECG with the previous ECG. An emergency medicine clinical dashboard was developed to address these difficulties.

Introduction

Fragmentation of patient information is a common problem in healthcare. Health information is seldom shared among competing healthcare delivery organizations, and even within a single organization, it is common for data to be isolated within various information 'silos.'[1] Adoption of electronic health records (EHRs) may help address some aspects of information fragmentation, but EHR systems themselves are fragmented, making it difficult for clinicians to easily review data that "belong together." For example, in our commercial EHR, laboratory results and medication orders are accessed through different modules that are not visible on the computer screen at the same time, even though reviewing these two types of data together makes clinical sense. This fragmented model for displaying patient information requires increased cognitive effort to obtain a holistic understanding of a patient. In turn, increased cognitive effort can lead to a higher rate of medical error.[2]

Related to the challenge of information fragmentation is the increasing awareness of gaps in clinicians' information needs. Stiell and colleagues found that physicians reported information gaps in one-third of patients presenting to the emergency department.[3] Of these information gaps, half were felt to be either very important or essential to patient care, they were found more commonly in sicker patients, and they were independently associated with a prolonged length of stay in the emergency department. Historical information (e.g. previous visits, past medical history) was the most common information gap among the studied emergency physicians.

Even when historical information is available to emergency physicians, they do not always access it,[4] especially if it is difficult or time-consuming to find.[5] Effective cognitive support—providing information in an optimal format to clinicians when and where it is needed—should be a foundational principle for designing any clinical information system. The importance of cognitive support was highlighted in the 2009 report of the U.S. National Research Council, "Computational Technology for Effective Health Care: Immediate Steps and Strategic Directions."[6] The report noted that current healthcare information systems force clinicians to "devote precious cognitive resources to the details of data," explaining that "without an underlying representation of a conceptual model for the patient showing how data fit together and which are important,…understanding of the patient can be lost."[6]

Dashboards have been defined as "a visual display of the most important information needed to achieve one or more objectives that has been consolidated on a single computer screen so it can be monitored at a glance."[7] Dashboards have been employed in a wide range of medical settings, including emergency medicine, otolaryngology, nursing care, and maternity care.[8-11] While clinical dashboards are typically used to summarize the status of a cohort of patients (such as an emergency department tracking board), we believe there is a pressing need for dashboards to

organize and efficiently display data for individual patients. We hypothesized that emergency medicine clinicians have specific information needs, that these needs are not adequately addressed by our existing electronic health record, and that a clinical dashboard could be created to fill the information gaps.

Methods

This IRB-approved study was performed at the Columbia University Medical Center emergency department, which has 126,000 annual visits and serves an urban, low-income population. A survey was used to elicit the general information needs of emergency medicine clinicians. Structured interviews were conducted to supplement the survey data and to identify situation-specific information gaps.

Survey

After a review of the survey methodology literature, a preliminary survey was developed. This online instrument adhered to the tenets of proper survey design, including limiting forced responses and allowing for free-text answer choices.[12] The survey questions were designed to clarify the clinical information items most important to emergency medicine clinicians. Questions were answered via a slider that could be moved continuously from 0 to a maximum score of 100; the default location of the sliders was set to 50.

The preliminary survey was iteratively refined based on feedback from an advisory committee composed of emergency medicine physicians and experts in qualitative research methods. The result of this process was a six-question survey instrument that was emailed to all emergency department attending physicians, fellows, and resident physicians using the Qualtrics Survey software (Qualtrics LLC, Provo, UT). A subsequent reminder email was sent approximately two weeks after the initial survey email.

The survey asked clinicians to consider their information needs while caring for a typical patient in the emergency department. The survey also inquired about which patient data items should be included in a clinical dashboard. To orient the survey respondents to the definition of a "dashboard" and the layout of a potential emergency medicine dashboard at our institution, a sample image of an ambulatory medicine dashboard was included in the survey. To avoid biasing respondents, the sample dashboard included information such as preventive care recommendations that were not especially relevant to the emergency environment.

Interviews

Structured interviews were conducted with emergency department faculty, residents, and midlevel practitioners while they were working in the emergency department. The interviewer (JS) followed an interview script that focused the conversation on information gaps that were present in the emergency department, specifically with respect to the hospital's information systems. Clinicians were asked about their "pain points" during an average shift and how the EHR could be modified to reduce frustration and improve efficiency. The interviews were coded using the grounded theory method, an inductive approach in which interview and observation data are coded and then organized into themes.[13] Data collection and analysis were performed concurrently; the interviews were conducted until theme saturation was achieved.

Dashboard Development

Based on the results of the survey and interviews, a dashboard display was designed and created. Our institution uses a commercial EHR product, Allscripts Sunrise (Allscripts Corp., Chicago, IL), in the emergency and acute care settings. A locally developed system called iNYP integrates with the EHR and provides advanced data review capabilities. iNYP is a Java-based service-oriented web application that builds on Columbia University's 25-year history of clinical information system innovation.[14-16] iNYP is available as a custom tab within the commercial EHR (supplementing the native results review capabilities) and can also be accessed from a web browser or a mobile device. At the time of the study, approximately 8,000 clinicians used iNYP alongside the commercial EHR each month. During the study, a new architecture based on HTML5 and JavaScript was added to iNYP to enable the creation of clinical dashboards. The dashboard architecture facilitated the display of data originating from disparate EHRs and from different locations within the same EHR. A comprehensive evaluation of the clinical use of the dashboard was outside the scope of the current study.

Results

Survey

Of 109 emergency department attending physicians, fellows, and resident physicians, 52 (48%) completed the online survey. The majority of respondents (62%) were attending physicians.

The clinical information items reported to be most helpful while caring for patients in the emergency department were vital signs, electrocardiogram (ECG) reports, previous discharge summaries, and previous laboratory test results, as shown in Table 1.

Table 1. Helpfulness while seeing average patient in ED

Survey Item	Average Score
Vital Signs	94.35
Previous ECG	92.04
Prior discharge summary	89.59
Prior lab results	84.73
Prior ED note	84.16
Something else*	74.06
Triage note	69.75
Guidelines	60.85
Immunizations	26.93

*Something else

Medication list - 4 respondents
Imaging results - 3 respondents
PMD phone # - 3 respondents
Ambulance note - 2 respondents
Allergies - 2 respondents
ED visits - 2 respondents
Clinic notes - 1 respondent

Table 2. Helpfulness of *historical* data in dashboard

Survey Item	Average Score
Something else*	92.2
Previous ECG	91.8
Past medical history	89.8
Prior discharge summary	87
Prior lab results	85
Prior ED note	79.3
Prior imaging	78.6
Immunizations	32

*Something else:

Medication list – 3 respondents
Vital signs – 2 respondents
Lab results – 1 respondents
Microbiology results – 1 responden

Table 3. Helpfulness of *active* data in dashboard

Survey Item	Average Score
Vital signs	94.35
Lab results	92.04
Current imaging results	89.59
Something else*	84.73
PMD phone #	84.16
Triage note	74.06
Reference Material	69.75

*Something else:

Don't show labs – 1 respondent
Meds given in ED – 1 respondent
Triage level – 1 respondent
Pending results – 1 respondent
Medication list – 1 respondent
Ambulance note – 1 respondent

The list of a patient's medications was the most frequently requested "Something else?" free-response item. Survey respondents identified triage notes, evidence based-guidelines, and immunization histories as less important.

After showing respondents an image of a sample ambulatory medicine dashboard, they were asked to identify the clinical information items that they thought would be most helpful for an emergency medicine dashboard. In terms of historical clinical information items, as shown in Table 2, the results suggested that previous ECG, past medical history, most recent inpatient discharge summary, and prior lab results would be most helpful.

For active clinical information items (i.e., from the current visit), as shown in Table 3, respondents reported that it would be most helpful to have vital signs, lab results, and imaging results in the dashboard. In contrast, information such as the private medical doctor's contact information, the triage note, and reference material were felt to be less helpful. In the "Something else" free-response component of the survey, one respondent requested that lab results not be shown in the dashboard because they could already be found elsewhere.

The final question allowed respondents to answer in a free-response manner the single feature they would most want to add to the existing EHR. The majority of answers were similar to those found in the other parts of the survey (e.g. medication list, previous results). However, there were two novel answers: 1) patient photograph and 2) a way for outside physicians referring their patients to the emergency department to have a means of communicating referral information directly into the EHR.

Interviews

Of the 18 interviews conducted, 8 were with attending physicians, 7 were with resident physicians, and 3 were with midlevel providers. The interviews lasted approximately 10-20 minutes. There were three key themes that emerged: 1) difficulty accessing current vital signs, 2) difficulty accessing current point-of-care tests, and 3) difficulty comparing the current ECG with the previous ECG.

The interviewees noted that although vital signs were very important to the emergency medicine clinician, their display in the EHR was both tedious to access and in a format that was time-consuming to comprehend. A similar sentiment was expressed regarding the results of the point-of-care tests, such as urine pregnancy. Because these results are hand-entered by nurses, they are found in a section separate from other laboratory test results. Clinicians complained that these results were "buried at the bottom of a long flowsheet," which was cumbersome and time-consuming to access.

Despite the fact that all ECGs were accessible in the EHR, it was not possible to compare two ECGs on the computer screen at the same time. Instead, clinicians were obliged to print one of the ECGs and compare it to the other on the screen, or more often, to print both of the ECGs and compare them side-by-side.

Dashboard Development

Based on the knowledge obtained from the survey and interviews, we designed a dashboard to address the information gaps of the emergency medicine clinicians. The dashboard provided summary "tiles" of five of the most-requested clinical information items: vital signs, point-of-care tests, ECGs, previous notes/discharge summaries, and medications. In designing the tiles, we considered the best practices of information visualization, such as adhering to location-based emphasis (i.e., placing the most important information in the upper left) and minimizing the amount of non-data pixel use.[17]

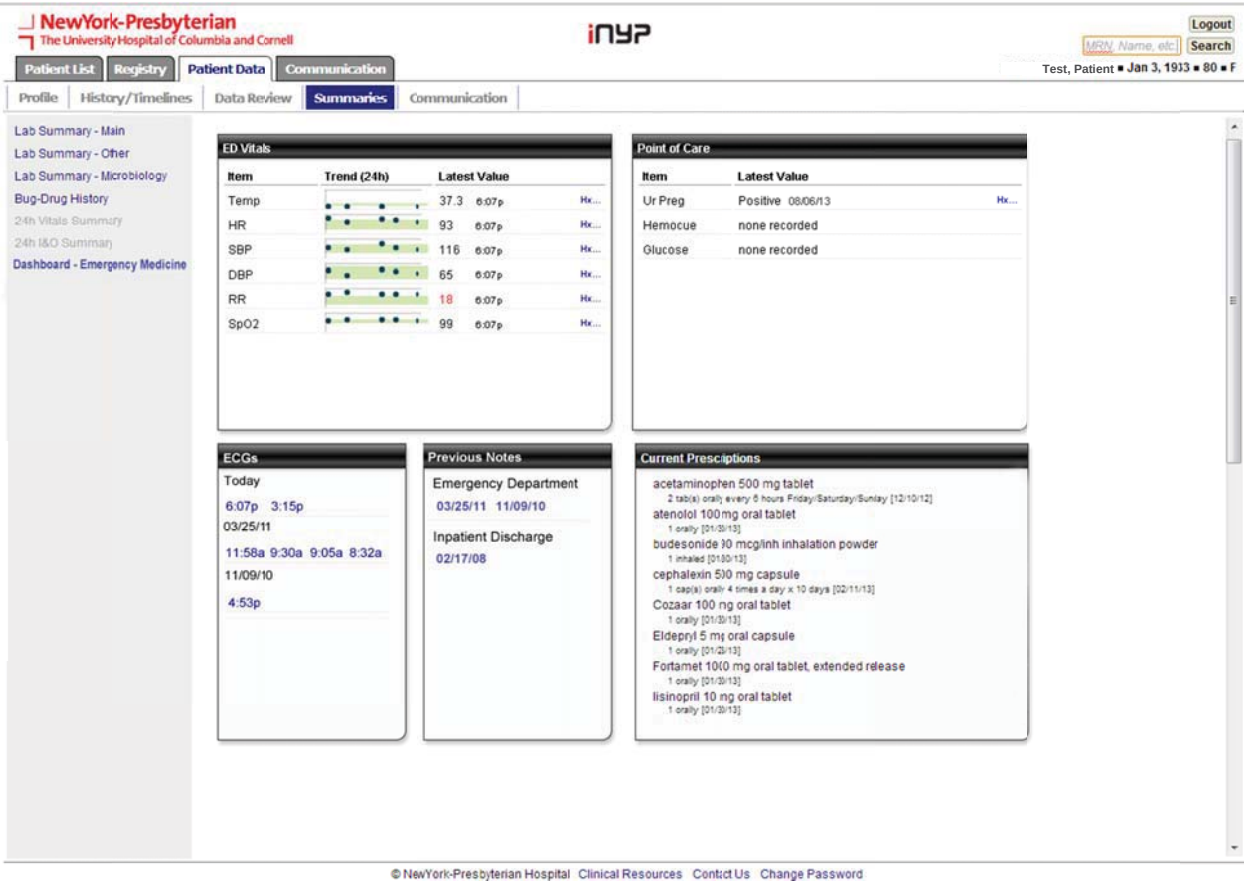

Figure 1. Screenshot of the Emergency Medicine Dashboard

The dashboard display is shown in Figure 1. The "ED Vitals" tile presents the patient's vital signs in graphical and tabular formats. The sparkline graphic provides a quick way to identify trends during a patient's stay in the emergency department. The shaded band indicates the normal range; data points that are abnormal (and therefore fall outside the band) are readily apparent. Alternatively, a more precise display of the same data can be found by reviewing the "Latest Value" column and clicking the history ("Hx") link, which pops up a display of the previous vital sign measurements. Abnormal values are marked in red font.

The "Point-of-Care" tile shows the results of the point-of-care tests performed at our institution: urine pregnancy, urine dipstick, finger-stick glucose, and finger-stick hemoglobin. If no results are available, "none recorded" is displayed. Similar to the ED Vitals tile, the history ("Hx") link displays any earlier point-of-care test result. This display is useful when clinicians need to follow a patient's finger-stick hemoglobin or glucose test during their stay in the emergency department.

The "ECG" tile divides electrocardiogram results by date. Clicking one of the hyperlinks launches a pop-up ECG viewer, which graphically displays the tracing in PDF format, along with the cardiologist's report (if available). Multiple ECGs can be viewed simultaneously by clicking on additional hyperlinks.

Similarly, the "Previous Notes" tile organizes discharge summaries and previous emergency department visit notes by date. Clicking the associated hyperlink launches a note viewer. Finally, the "Current Prescriptions" tile shows the name, dosage, and dosing schedule for the patient's home medications.

Discussion

In order to design clinical information systems that minimize data fragmentation, it is necessary to know which clinical information items are most important to the users of the system. Information needs of clinicians do not follow a "one-size-fits-all" model: a given specialty cohort of clinicians may use information systems in a much different way than their colleagues who work in a different setting or come from another specialty. Once information needs of a specific group are known, extra care can be given to the design of clinical information systems to ensure that various workflows are supported and data are presented in a way that makes "clinical sense."

Our qualitative investigation of the information needs of emergency medicine clinicians demonstrated both the information needs of the average emergency medicine clinician as well as institution-specific information gaps in our EHR system. We found that vital signs, current and previous ECG, previous discharge summary, lab results, and medication list were particularly important; this finding is probably applicable to most emergency care settings. Our investigation also showed that at our institution, there were information gaps related to the inefficient display of these clinical information items.

Our institution is not unique; many (if not all) clinical information systems have been designed with inadequate usability testing and apparent lack of clinical input.[18] Our study provides a methodology by which the information needs of a specialty-specific group of clinicians can be assessed. In turn, this can inform the development of specialty-specific dashboards that fill information gaps.

The clinical dashboard we created was designed based on the feedback elicited from clinicians who used the information systems regularly. The information gaps that were identified were related to vital signs, lab results, ECGs, and discharge summaries, all of which were felt to be among the most important clinical information items by the clinicians. In order to fill these gaps, individual tiles were created within the clinical dashboard to enable at-a-glance monitoring and access to these items.

In the future, we envision "smart dashboards," which dynamically change based on the chief complaint of the patient. For example, a patient who presents to the emergency department with a chief complaint of "laceration" would have his tetanus status displayed, whereas different information might be surfaced for someone presenting with chest pain. This in turn might inform the development of universal rules of clinical data display. For example, a patient's creatinine level and pregnancy status (if appropriate) should always be shown when ordering a computed tomography (CT) scan. Similarly, a previous ECG, when available, should always be shown next to the current one. We believe that improved information displays will better support the cognitive tasks of clinicians.

Our study has several limitations. First, the survey response rate was 48%, reflecting a possible bias because of differences in the types of subjects who completed the survey versus those who did not. In any case, this study at least reflects almost half of the relevant clinicians. Second, a single investigator conducted the structured interviews. While an interview script was used, it is possible that the way in which questions were asked biased the respondents in their answers. Third, because our study relied on survey and interview, it is subject to recall bias. Observation

could be used in future studies to confirm the interview and survey results. Fourth, we have not yet implemented the dashboard within the emergency department. Fifth, the study was performed at only one emergency department with only one electronic health record. Our findings may not generalize to other environments or EHR systems. Nevertheless, we believe our results can help inform EHR vendors about the information needs of their users and also encourage the investigation of clinical information needs in diverse settings.

Conclusion

Electronic health records suffer from data fragmentation, which adversely affects patient care. Our study presented a methodology by which the information needs of a specialty cohort of clinicians can be studied. We demonstrated how a better understanding of clinicians' information needs can inform the development of specialty-specific clinical dashboards that provide cognitive support and improve efficiency.

SOEMPI: A Secure Open Enterprise Master Patient Index Software Toolkit for Private Record Linkage

Csaba Toth[1], MS, Elizabeth Durham[1], PhD, Murat Kantarcioglu[2], PhD, Yuan Xue[3], PhD, Bradley Malin[1,3], PhD

Abstract

To mitigate bias in multi-institutional research studies, healthcare organizations need to integrate patient records. However, this process must be accomplished without disclosing the identities of the corresponding patients. Various private record linkage (PRL) techniques have been proposed, but there is a lack of translation into practice because no software suite supports the entire PRL lifecycle. This paper addresses this issue with the introduction of the Secure Open Enterprise Master Patient Index (SOEMPI). We show how SOEMPI covers the PRL lifecycle, illustrate the implementation of several PRL protocols, and provide a runtime analysis for the integration of two datasets consisting of 10,000 records. While the PRL process is slower than a non-secure setting, our analysis shows the majority of processes in a PRL protocol require several seconds or less and that SOEMPI completes the process in approximately two minutes, which is a practical amount of time for integration.

Introduction

Healthcare organizations (HCOs) are encouraged, or are required, to share data to support various endeavors, such as post-market surveillance and biomedical research. To mitigate bias in investigations, it is important to resolve when a patient's data resides in multiple resources. This process, called record linkage, is non-trivial because a patient's record often contains typographical and semantic errors.[1] Sophisticated record linkage strategies have been proposed to resolve these problems[2], but their application is hampered by policies or regulations, such as the HIPAA Privacy Rule[3], which limit the sharing of identifiers that facilitate the linkage process (e.g., personal name and Social Security number). To overcome this barrier, a growing list of techniques has been proposed to support private record linkage (PRL).[4]

From a high level, the PRL process has a lifecycle that entails (but is not necessarily limited to) the following steps:

1. Generation and storage of keys for cryptosystems, or salt values for hash functions, invoked in a PRL protocol;
2. Communication of keys and salt to the entities encoding the records upon request;
3. Transformation of identifiers into their protected form as specified by the protocol;
4. Execution of the record linkage framework (e.g., feature weighting, blocking, and comparison of record pairs to predict which correspond to the same individual); and
5. Transfer of records and parameters related to the linkage protocol (i.e., all communication between parties).

Unfortunately, there has been a lack of transition of sophisticated PRL techniques into practice. We suspect this is due, in part, to factors associated with: i) complexity in the description and design of protocols, ii) availability of working software, and iii) coverage of the data lifecycle.

Regarding the first factor, a wide variety of methods exist to support PRL. For instance, let us focus on one aspect of step four of the lifecycle for a moment. There are many techniques that have been proposed for computing the similarity of strings in a privacy preserving manner. Some of these are based on secure multiparty computation (SMC) protocols (e.g., [5]). Others are based on less cryptographically intense approaches, such as mapping the identifiers to Bloom filter encodings (BFEs)[6-8]. Hybrid strategies selectively reveal information (e.g., patient's age as a 5-year range) to speed up the SMC process[9]. These methods vary considerably in their effectiveness (e.g., precision and recall), efficiency (e.g., computational runtime, memory required, and bandwidth), and security[11].

Second, even when PRL techniques appear to balance these factors, they may not be adopted because it is argued that they require more engineering than a simple protocol[12]. In many respects, this is a valid argument because the majority of published PRL methods are often limited to software implementations developed for experimental

analysis. HCOs that wish to use such strategies would be hindered from doing so without significant additional engineering. This is problematic because most HCOs have neither the time nor resources to interpret and implement cryptographic procedures into an easy to use software product. To the best of our knowledge, there are only two tools[13,14] (as reviewed below) which explicitly provide readily available software that supports PRL methodologies.

Third, to the best of our knowledge, all published PRL methods, as well as the software disseminated in support, tend to focus on the linkage stage of lifecycle only. In other words, they assume that HCOs have the ability to manage patients' records, establish communication links, and execute linkage procedures. Consider, a certain subset of PRL methods require HCOs to work with a third party to more appropriately balance efficiency and security.[4] Yet, this assumption does not hold true and, thus, the PRL methods in the literature, as well as the aforementioned software tools, fail to cover the lifecycle. This, again, requires HCOs (or research data managers) to piece together or augment certain software tools.

Given the aforementioned challenges, we developed an open source software toolkit to support the PRL lifecycle. Thus, there are several contributions of this paper:

1. **Open source software framework for PRL:** We extend an existing open source master patient indexing tool[15] to handle the record linkage process in a manner consistent with accepted frameworks. The resulting software, called the Secure Open Enterprise Master Patient Index (SOEMPI), entails an innovative architecture to tailor the specification of PRL protocols to an HCO's needs. In doing so, SOEMPI manages the communication between disparate data providers, as well as the third parties, involved in the PRL process. Furthermore, the architecture of SOEMPI is implemented in a component-based manner and is readily extensible to PRL approaches that follow the aforementioned lifecycle.
2. **Case Studies in PRL Protocol Implementation:** We implement several PRL protocols to illustrate the capability of SOEMPI. All protocols are based on a Bloom filter-based record transformation method proposed in the literature. In these protocols, HCOs hash the patient identifiers in their respective medical record systems into Bloom filters encodings (BFEs). Based on a recently published protocol, each variable is encoded in its own filter, which are subsequently combined into a single composite filter, with bit positions weighted to optimize linkage performance.[16] These encodings are subsequently sent to a third party for linkage.
3. **Runtime Analysis:** To demonstrate the feasibility of SOEMPI, we perform an analysis over the PRL lifecycle. We compare the running time between SOEMPI and OpenEMPI and show the communication and transformation required for PRL is relatively short, such that it can be completed in a practical amount of time. Given that the accuracy of such strategies has been addressed[6], this paper focuses on an evaluation of runtime.

PRL Participants and Protocols

This section begins with a review of record linkage and PRL. We then proceed into describing common participants of the linkage schemes and finally describe two actual protocols.

Record linkage is a data management process. At its core, it consists of two or more data managing HCOs who wish to integrate disparate collections of records. The process of record linkage requires the transfer of data from one HCO to another, who performs a data comparison and integration procedure. This procedure may be deterministic and rule-driven[17] or probabilistic and supported by robust statistical inference methods (e.g., the expectation-maximization implementation of the Fellegi-Sunter (FS) algorithm[18]). In PRL, the set of entities may be expanded to include one or more third parties (i.e., non-contributors of data). As we explain in further depth below, these parties can take on a variety of responsibilities, ranging from the generation and communication of cryptographic keys for the HCOs to the execution of the integration process on behalf of the HCOs in a manner that prevents the inference of patients' identifiers. Thus, before proceeding into the details of existing systems, we take a moment to review the classes of participating entities described in various PRL systems and their responsibilities.

Data Providers (DPs) are the HCOs who manage the identified patient records that will be linked. Without loss of generality, Let us focus on two disparate patient data holder HCOs, Alice and Bob. They engage in record linkage sessions with other HCOs through the third parties.

Key Server (KS) provides "salt" and/or cryptographic key values needed by the DPs, so that they can perform data transformations (e.g., generation of BFEs) of their data fields in a consistent manner.

Data INtegrator (DAN) performs the integration component of the PRL process for the HCOs. DAN may accept encoded values (e.g., BFEs) from the DPs and performs record integration in a privacy preserving manner.

PArameter Manager (PAM) receives sample data from the DPs to determine the parameters of the linkage protocol (e.g., number of bits in a Bloom filter). It coordinates the communication of such parameters to the DPs.

A. Three-Party PRL Protocol

As an example, let us consider a PRL protocol with one third party as shown in the blue-shaded section of Figure 1. In this protocol, DAN requires Alice and Bob to encode their patients' identifiers using a consistent set of salted (i.e., keyed) HMAC (Hash-based Message Authentication Code) functions. As such, it is often asked, "Where do these keys come from?" In the first variation of the protocol illustrated, we integrate an independent, semi-trusted authority in the form of key server KS to generate the salts for Alice and Bob. In Figure 1, the sections shaded in blue depict a sequence diagram that summarizes the series of steps and service calls. After receiving the salts, Alice and Bob encode their records into BFEs based on a salted hash function. The resulting encodings are then submitted to DAN, who waits until both datasets and match request tickets (explained below) have been received. Upon reception, DAN runs the requested matching procedure.

B. Four-Party PRL Protocol

Recent research has shown that if the BFEs submitted to DAN are not tuned properly, they are vulnerable to cryptanalysis and leakage (e.g., mapping of an encoded value to a patient's real name).[7] To mitigate such an attack, Alice and Bob should parameterize their BFE strategy in a manner that minimizes cryptanalysis, but maximizes accuracy.[16] Due to privacy concerns, Alice and Bob cannot exchange patient identifiers directly, but may wish to employ the assistance of an additional third party to provide feedback on how best to setup the system (e.g., determine weights for each field, such as forename, surname, and Social Security number). This is where a parameter manager, PAM, can be of assistance.

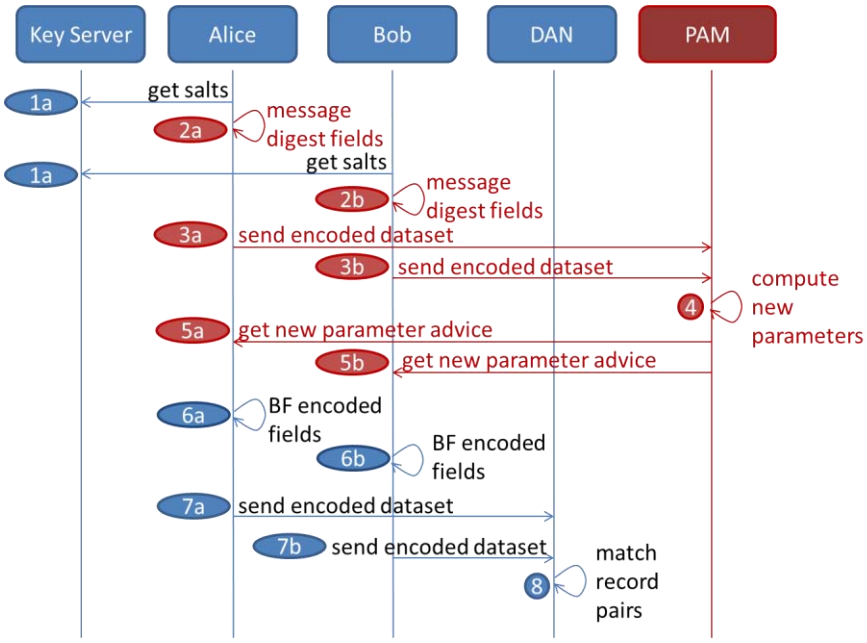

Figure 1. An illustration of the flow for a private record linkage protocol that incorporates multiple third parties. The blue sections of the flow correspond to a third-party protocol, while the incorporation of the red-shaded sections convert it into a four-party protocol. In this diagram, the variables *a* and *b* are used to denote the steps associated with Alice's and Bob's datasets, respectively).

In Figure 1, the sections shaded in red provide additional support for such a process. In this case, Alice and Bob request and receive salts from KS as before. However, instead of sending data to DAN, they provide a small sample of their HMAC encoded records to PAM. This entity compares the datasets (as described elsewhere[16]) and responds to Alice and Bob with the appropriate set of parameter values (e.g., size of Bloom filter, number of hash functions, size of the *n*-grams into which patient identifiers should be split, and random order of bits into which the hash functions will be mapped). The protocol then continues in the same manner as described in the third party protocol.

Background: the State of PRL Software

This section provides a systematic analysis of existing free software solutions for master patient indexes (MPI), record linkage, and PRL. Table 1 summarizes various aspects of software tools for record linkage and PRL that are readily available. The majority of the software suites in the table are limited in that they were developed to facilitate the integration of specific datasets in a non-coordinated manner. Moreover, they are limited to the user interface of a local machine and, thus, their main deployment is for desktop-level usage. While it is easier to install desktop

software than to deploy it as a server application, it significantly limits its scalability. If such software was installed on a server, for instance, interaction would only be possible through a remote desktop protocol. Because this functions in a stand-alone manner, it is beyond its scope to support any protocol in an automatic fashion that involves multiple participants.

Table 1. A systematic comparison of existing generic and privacy preserving record linkage software tools.

Tool	PRL	Free	Open Source	Extensible	Communication[a]	GUI[k]
Link King[21]	No	No[c]	Yes	Limited[e]	Manual	Desktop[b]
Link Plus[20]	No	Yes	No	No	Manual	Desktop[b]

OpenMRS[23]	No	Yes	Yes	Yes[g]	Yes[h]	Web[j]
RECLINK[22]	No	No[c]	Yes	Limited[e]	Manual	Desktop[b]
SOEMPI	Yes	Yes	Yes	Yes[g]	Yes[i]	Web[j]

[a] Communication with other entities.
[b] Requires graphical desktop sharing solution on server and client side to view the graphical user interface of the server locally.
[c] The script is free in itself, but requires additional SAS or Stata license to run.
[d] Proposed, but not implemented.
[e] The software is not free, and requires specific programmer knowledge.
[f] BloomEncode and SafeLink sourcecode is available only for research projects.
[g] SOA software by nature designed for extensibility, but also require programmer knowledge.
[h] With standard HCO actors, but not in a complex record linkage protocol.
[i] With other SOEMPI instances for record linkage.
[j] Users can view graphical interface of web applications remotely with a browser easily by nature
[k] Graphical User Interface

Most of these software tools enable a data cleaning process and support the tuning of record linkage parameters. They are all capable of performing FS-style probabilistic record linkage and most have rich and detailed user interfaces. The Fine-grained Record Integration and Linkage (FRIL) tool even aids in the execution of several consecutive match runs, where the outcome of each run iteratively helps refine parameters.[19] Link Plus is free, however, it is closed source and only available for Windows.[20] Link King[21] and RECLINK[22] are both based on statistical software suites (SAS and Stata, respectively) which require licenses, but they are free and open source additions. However, this means that their extensibility requires scripting knowledge of the specific statistical package.

A. Open Source Master Patient Indexing

Distributed healthcare systems require systematic approaches for coordination, integration, and management of linked records. One way this has been accomplished is through master patient indexing (MPI) initiatives, which have been integrated into health information exchange systems. Many of the resulting technologies have been implemented as open source software tools. OpenEMPI[15] is an open source MPI project with ongoing development. It is capable of performing deterministic and probabilistic matching and supports MPI. Every aspect of the record linkage process is configurable. It can interface with various health information systems in a standardized manner. The software is based on a service-oriented architecture (SOA) design and a component framework, which makes it extensible. OpenMRS[23] was designed to support the delivery of healthcare in developing countries. It has a matching module that is configurable and capable of performing probabilistic matching. Other open source MPI systems, such as the OpenEMed[24] and OpenHRE[25], have not been supported for years and, thus they were not considered further. It is worth noting that these solutions only address record linkage and patient indexing and do not support PRL.

B. Open Source Private Record Linkage

In comparison to the various options for record linkage tools, the PRL landscape is more barren. The developers of the Freely Extensible Biomedical Record Linkage (FEBRL)[26] tool, for instance, planned to implement PRL methods based on *n*-gram hashes[27], but this has yet to be realized. To the best of our knowledge, there exist only two actual PRL implementations. The first corresponds to the BloomEncode and SafeLink companion tools for the Merge ToolBox (MTB) software.[28] To facilitate PRL, the BloomEncode tool is invoked to transform patient identifiers into BFEs. These are then manually passed to a third party who runs the MTB system and performs record linkage. The other is the LinkIt companion tool of FRIL.[29] We wish to highlight, however, that to realize a fully automated PRL lifecycle, MTB or FRIL/LinkIt would need communication protocols to interact with the companion tools at disparate organizations securely.

Methods

In this section, we describe the PRL lifecycle and how it is supported by the SOEMPI architecture.

A. Requirements

In preparation for this project, we performed a requirements analysis to identify the factors in an existing record linkage software that support the PRL lifecycle. From the outset, it was determined that such a system should have the following properties:

1. Coverage of the entire PRL process;
2. Configurable to support various parameterizations of data schemas, record linkage methods, as well as encoding functions, blocking strategies, and record comparison / matching algorithms;
3. Flexible to facilitate various data schemas at the data providers and the design of different PRL protocols;
4. Enterprise environment capable of enabling the scalable deployment of the software on a server or in a data warehousing environment; and
5. Open source technology to allow for extension and revision by a community;
6. Use of industry-wide accepted technologies for easier communications with possible non-PRL HCO software.

OpenEMPI was selected as a code base because it satisfies most of these properties and is currently maintained.

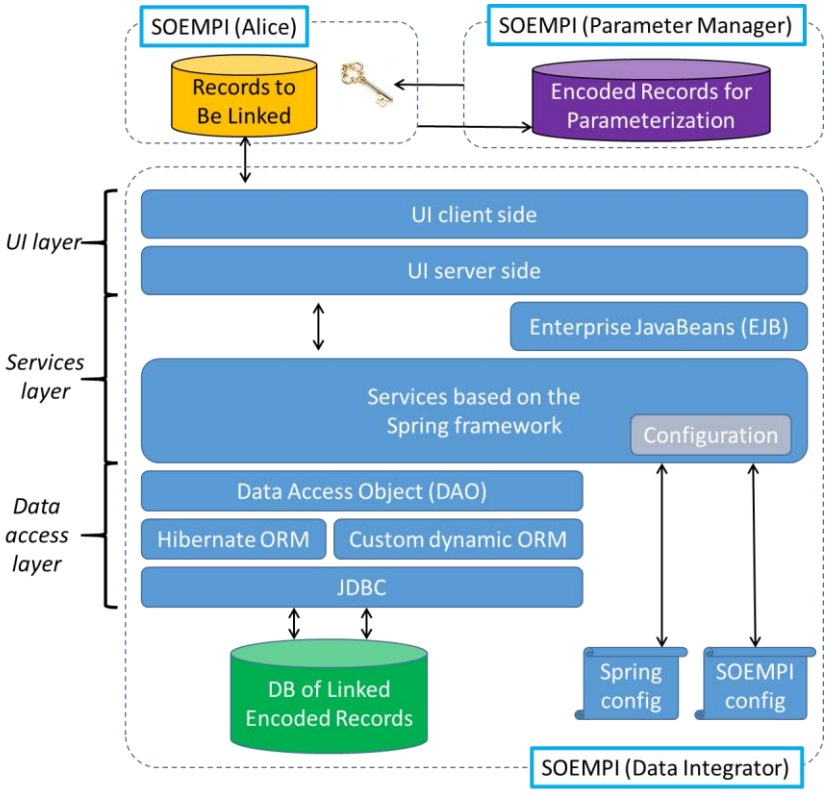

Figure 2. A high-level architecture of the SOEMPI software

B. Software and Communications Architecture

This section begins with a high-level overview of the SOEMPI design, composition, and main building blocks. Next, we provide an overview of the pluggable architecture associated with SOEMPI, which allows for flexible management of the lifecycle. Then, we take a closer look at certain key functionalities in the software design. Finally, we discuss how the various participating entities and data schemas are supported.

1. Architecture of a SOEMPI Instance

Figure 2 provides a high-level view of a SOEMPI instance. This view is based on an *n*-tier design, which facilitates responsible isolation and decoupling of processes. Specifically, the user interface layer (both client- and server-side) at the top interacts with the middle services tier below, which connects to the data access layer, and finally connects to the underlying database. Under the hood, an SOA is applied to achieve a flexible and pluggable architecture.

While many record linkage protocols involve several parties, SOEMPI serves as a universal actor because it can be instantiated according to each of the possible roles described earlier. The actual role played can be selected through either a configuration file or during the login process. According to the selected role, SOEMPI displays only the relevant features on the user interface of the particular role and is restricted to perform only the appropriate operations (e.g., when acting as a Key Server, it can only generate and distribute salts). If additional SOEMPI instances are involved in the protocol (e.g., a third party), the programs communicate with the help of Java EJB remote calls, a method inherited from OpenEMPI.

2. Pluggable Services

While the complete details of SOEMPI are beyond the scope of this paper, we wish to highlight the pluggable aspect of the components in the PRL process. This is one of the key contributions because it enables a modular approach to PRL protocol design and deployment. Figure 3 depicts the steps of the PRL process and how each step offers various encapsulated method options. For instance, SOEMPI offers a variety of record comparison functions, blocking algorithms, and probabilistic matching methods. The composition of a method-chain is possible through specification in an XML configuration file or runtime user interface interaction.

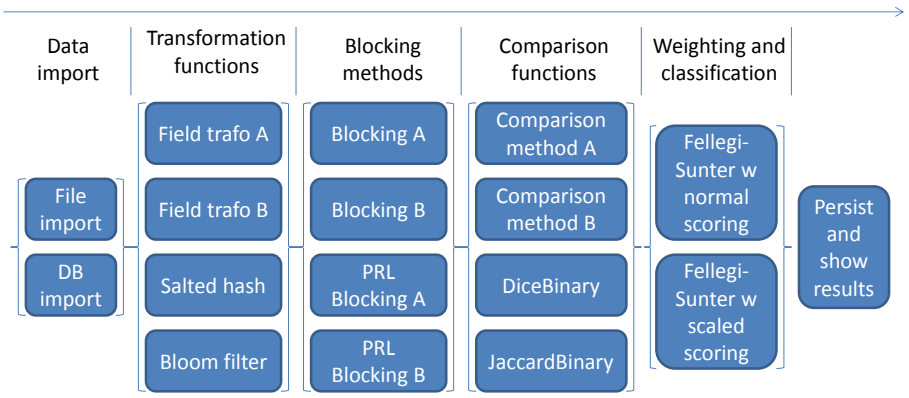

Figure 3. A depiction of the pluggable service architecture for the record encoding and matching functionality of the SOEMPI system.

3. Dynamic Data Schemas

Given that we cannot predict which patient-specific attributes will be utilized for record linkage purposes, SOEMPI should be able to store any type of data and database tables with diverse schemas. We designed SOEMPI to store multiple instances of flexible typed datasets (any number and type of fields). This requirement derives from real-world scenarios where, for example, mother's weight and newborn's weight are required (both are floating point data types). The software was designed such that each imported dataset has its own table in the underlying database, as well as an entry in a registry table which keeps track of the uploaded datasets. Likewise, when SOEMPI links records, it creates a new table for the resulting join, and updates a registry documenting which tables were joined. SOEMPI still leverages a conventional persistence layer (i.e., object relational mapping tools) whenever possible (i.e., user management, sessions, etc.), but uses a custom flexible persistence layer when necessary.

Performance Analysis

In this section, we compare the running time of OpenEMPI to SOEMPI with respect to a certain PRL protocol to illustrate how time and computation are influenced by the privacy preserving procedures.

A. Experimental Design

To allow for reproducibility, we performed our experiments with records from the publicly available North Carolina Voter Registration (NCVR) database, which, at the time of this study, consisted of 6,190,504 records. We generated 10 datasets, each of which consists of 10,000 randomly selected records over the following fields: *Forename*, *Surname*, *City (of Residence)*, *Street Name (of Residence)*, *Gender*, and *Ethnicity*. From each dataset, we created a

corresponding "corrupted" dataset for matching purposes as described by Durham et al.[16] In doing so, every field of each record is subject to a corruption procedure, a part of the SOEMPI toolkit, that extends the strategy implemented in FEBRL[26] (which is based on research by Christen and Pudjijono[31]). This procedure introduced *character-level* errors at rates consistent with those reported in practice. These included optical character recognition (OCR) errors (e.g., S swapped for 8), phonetic errors (e.g., ph swapped for f), and typographic errors (e.g., insertions and transpositions). In our experiments, these corruptions occurred with the following probabilities: insertions and deletions: 0.15, phonetic errors: 0.03, OCR errors: 0.01, substitutions: 0.35, and transpositions: 0.05. To further simulate record linkage challenges faced by HCOs, our extensions introduced errors at the *value-level*, such as the use of a nickname or a change in residential address. First, nicknames based on the Massmind database[32] were substituted for Forenames with probability 0.15. Second, surnames were substituted, using the U.S. Census names data[33], for females (e.g., changes due to marriage) with probability 0.1, for males with probability 0.01, and were hyphenated with probability 0.01. Third, street names were changed with probability 0.1 using a random selection from the entire NCVR dataset.

For OpenEMPI, we considered a record linkage framework that involved three parties: Data Providers Alice and Bob and a Data Integrator DAN. The Data Providers transformed the Forename and Surname fields using double metaphone (a phonetic encoding algorithm designed to mitigate noise) during the import of the datasets. These are appended as additional fields to the datasets, which are then passed onto DAN, where a blocking procedure in the form of the sorted neighborhood algorithm is performed in two rounds over these fields. The matching protocol consisted of an Expectation Maximization-based (EM-based) FS algorithm.

For PRL, we used the Four-Party protocol described above. During the Parameter Manager phase, Alice and Bob transferred 1,000 random samples to PAM in an HMAC-encoded form. PAM then performed an EM-based FS algorithm to determine the parameters of the Bloom filter representations of the records as described elsewhere.[16] After Alice and Bob transferred their BFEs to DAN, blocking is performed through three rounds of a clustering processing based on locality sensitive hashing (LSH), where each seed of a cluster corresponds to 10 bit positions randomly sampled from the Bloom filter schema. Finally, DAN measured the similarity of record pairs (one BFE contributed by Alice and one contributed by Bob) in each cluster (using a Dice similarity function) in the same blocks to link records to their best match.

For each experiment, we matched the clean version of a given dataset to its own corrupted counterpart and reported on the average (and standard deviation) time for the 10 runs. We measured the time required to 1) import the data, 2) exchange data, and 3) execute various aspects of the linkage algorithm. All experiments were run on a single Quad-core Intel i7-2670QM processor @ 2.2GHz with 12 GB system memory. The majority of the computations were measured natively on the operating system. The data transfer measurements were performed between one SOEMPI instance running on the native OS and one running in a virtual box. Figure 1 depicts the specific steps in the process that were measured.

B. Findings

Our results focus on i) the bandwidth required to transfer and manage datasets for record linkage and ii) the time required to complete the record linkage protocols.

Bandwidth Required

In the non-privacy preserving environment, datasets transferred for record linkage required 550 KB. The size of the privacy preserving BFE datasets depend on their length of the Bloom filters, which itself is dependent on records involved in the linkage process. The length of the BFE is determined by PAM during the Parameter Manager phase. Over the 10 runs of our protocol, the average recommended size of the Bloom filter was 9,217 bits, with a standard deviation of 2,197 bits. However, size ranged from a minimum of 7,133 to a maximum of 12,904, such that the size of the datasets transferred for private record linkage to DAN for integration ranged from approximately 8.9 MB to 16.1 MB. It should also be noted that the runtime of the PRL matching process is greatly influenced by the number of bits used in the LSH-based blocking process, as well as the number of rounds of blocking. Since the goal of this paper is to report on how the communication protocol influences the time necessary to perform PRL, we note that such a sensitivity analysis is beyond the scope of this paper and refer the reader elsewhere for a discussion on Bloom Filter record linkage[8] and LSH blocking accuracy[34].

Time to Complete Protocol

Before comparing the record linkage protocols, it is important to note that for each step in SOEMPI in which a participant initiates communication with another participant the first time, a one-time authentication procedure must take place. This authentication necessary to establish a secure connection and incurs a fixed cost of 8-9 seconds.

Turning our attention to a comparison of the protocols, Table 2 provides a summary of the results and a breakdown by process. Here, there are several notable findings to highlight. First, the Four-Party protocol incurs three additional categories of cost in comparison to the conventional record linkage method. The first corresponds to the request and dissemination of salt values from the Key Server, which required approximately 9.5 seconds. The majority of this time, however, is spent in authentication and is a fixed cost, which will decrease in its relative contribution to the overall runtime as datasets grow in size. The second corresponds to another fixed cost associated with the FS-based matching step performed at PAM. It can be seen that the Parameter Manager phase is quick. This is due, in part, to the fact that PAM performs an exact matching protocol (as opposed to a similarity comparison) because each record is represented by a single HMAC only. The cost is kept relatively low also because PAM performs this step over a subsample (1,000 records) of the datasets. The third additional cost corresponds to Bloom filter generation. This cost comes from the PRL match step, which is more variable in terms of running time.

Overall, the non-secure process requires around one minute, while the secure process requires about one and a half minutes. Though the secure process is roughly 1.5X slower, it should be recognized this is a relatively fixed cost. The majority of this increase is due to parameterization of the record encoding process. The record linkage process (step 8) itself is only 1.2X slower, which derives from the fact that it takes more time to compare two Bloom filters or several thousand bits (see bandwidth findings) than comparison over each person-level field used in this study.

Table 2. Average time (+/- standard deviation) in seconds for 10 runs across each step of the linkage protocols. Private record linkage (PRL) corresponds to the Four-Party protocol in Figure 1 via SOEMPI, while non-private record linkage (non-PRL) is the standard record linkage protocol in OpenEMPI. The steps seen here correspond to the protocol steps depicted in Figure 1. (a+b) refers to operations done both on Alice's and Bob's dataset (Figure 1).

Linkage Step	PRL	Non-PRL
0: Import datasets	6.70 (0.59)	5.58 (0.73)
1 (a+b): Obtain salts	0.09 (0.02)	-
2 (a+b): Message digest fields	0.04 (0.01)	-
3 (a+b): Send encoded datasets	2.31 (0.08)	-
4: Compute new parameters	5.32 (0.77)	-
5 (a+b): Obtain parameter advice	<0.01 (<0.01)	-
6 and 7: Create BFEs and send data	20.11 (3.36)	5.95 (0.38)
8: Block and match record pairs	58.74 (42.70)	47.86 (3.61)
Total Time required	**86.13 (43.52)**	**59.78 (4.12)**

Discussion

The findings from our experimental investigation illustrate that the lifecycle of private record linkage (using BFE encodings and a Four-Party protocol) is slower and requires more bandwidth than record linkage over identifiable patient records. However, at the same time, our results show that the costs do not incur drastic loss in speed or increase in memory footprint and that the PRL process lifecycle can be completed in a practical amount of time. At the same time, though SOEMPI was designed to be flexible, configurable, and enterprise capable, there are certain limitations to our current implementation that we wish to highlight, which can be enhanced in the future.

First, it should be recognized that the evaluation was a pilot study only. As such, the empirical analysis was performed over a dataset of 10,000 records only with a specific blocking and record linkage algorithm. Many of the authentication steps and transmission of key / salt processes will have negligible changes as the various parameters of the PRL process are changed. However, the speed of the system will vary with the size of the dataset, length of the Bloom Filter, and number of bits sampled for LSH change scalability of the system. It is thus recommended that a more comprehensive scalability assessment be performed before applying SOEMPI in larger record linkage frameworks.

At the same time, we wish to point out that the majority of SOEMPI operations are engineered to run in single-threaded processes. However, many of the procedures can be translated into multi-threaded versions, particularly LSH-based blocking[35] and record matching[36] to take advantage of modern parallel computing frameworks, such as MapReduce.

Second, from a PRL perspective, though SOEMPI can handle communication between the various participating entities, it does not implement any of the cryptographic primitives or protocols that have been proposed in PRL protocols based on secure multiparty computation (SMC). However, SOEMPI can readily incorporate various crypto-toolkits that have been implemented in Java (e.g., the UTD Paillier toolkit[37]). We believe SOEMPI can be an environment for integrating and managing various PRL protocols in a plug-and-play manner. Other Bloom filter-based solutions could be implemented with small effort in SOEMPI.

Third, from a technical stance, there are several aspects of the system that can be improved. Notably, EJB may not be the best technology for remote communication in the case of record linkage. While it is ideal for serving concurrent and independent web queries, as well as exchanging individual patient records, PRL has different needs. In particular, certain PRL protocols may require longer runtimes, as well as concurrent computations where threads should exchange information. To address these needs, special care will be required to increase the timeout values of the system and achieve synchronization. Moreover, our customized persistence technology supports only the PostgreSQL database management system (DBMS). However, SOEMPI uses standard database connectivity and thus is readily extensible to other DBMS technologies.

Finally, the virtual machine's JBoss application server is not fully secured and a SSL communication layer must be configured. As such, SOEMPI will need to undergo some additional security hardening when applied in the real world settings.

Conclusions

This paper introduced an open source software suite to support the private record linkage (PRL) lifecycle. SOEMPI's root goes back to extensively tested and proven existing Open Master Patient Index (OpenEMPI) reference implementation software to manage, transfer, and perform record linkage over encoded patient identifiers, but it is modified and enhanced in several key areas. We performed a meta-analysis to compare and contrast the proposed software toolkit with various freely available record linkage and PRL software toolkits that have been available to the biomedical research community. In addition to describing the software architecture and curtails of the specific technologies leveraged to realize the SOEMPI in working code, we provided a high-level depiction of how to build several PRL protocols. These protocols demonstrate how multiple third-parties, as well as data providers, can be integrated through a common communication and software system to cover the lifecycle. We also provided a runtime analysis of a Bloom filter-based PRL protocol that incorporates the lifecycle of encoding, blocking, and matching, and showed that such a procedure can complete in a practical amount of time.

Abstract

Background. Clinical Decision Support Systems (CDSS) incorporating justifications, updating and adjustable recommendations can considerably improve the quality of healthcare. We propose a new approach to the design of CDSS for empiric antibiotic prescription, based on implementation of the deeper medical reasoning used by experts in the development of clinical practice guidelines (CPGs), to deduce the recommended antibiotics. Methods. We investigated two methods ("exclusion" versus "scoring") for reproducing this reasoning based on antibiotic properties. Results. The "exclusion" method reproduced expert reasoning the more accurately, retrieving the full list of recommended antibiotics for almost all clinical situations. Discussion. This approach has several advantages: (i) it provides convincing explanations for physicians; (ii) updating could easily be incorporated into the CDSS; (iii) it can provide recommendations for clinical situations missing from CPGs.

Introduction

The first Clinical Decision Support Systems (CDSS) were developed in the 1960s. Many were expert systems, designed to provide support for diagnosis and/or treatment decisions in a particular medical domain. Their development required collaboration between a medical expert and a computer scientist[1], with the medical knowledge and reasoning of the expert captured and implemented by the computer scientist. For example, INTERNIST-I[2] was a rule-based expert system providing support for multiple, complex diagnoses in general internal medicine. MYCIN[1] was a rule-based expert system developed for the diagnosis and treatment of infectious diseases.

In the 1990s, the concept of "Evidence-Based Medicine" was introduced and defined as "the integration of best research evidence with clinical expertise and patient values"[3]. This new paradigm led to the production and diffusion of Clinical Practice Guidelines (CPGs) by national health authorities[4]. CPGs are documents written by a group of experts for a particular domain, recommending diagnostic and therapeutic strategies on the basis of a systematic review of the available clinical evidence. However, CPGs are long, complex, textual documents that are difficult to use in daily clinical practice[5]. Many CDSSs were then designed to implement CPGs[6], rather than the medical knowledge of a single medical expert, to overcome these limitations and to take the concept of "evidence-based medicine" into account. Several formalisms were developed to facilitate and standardize the implementation of CPGs (e.g. Arden Syntax, EON, GLIF). These formalisms made it possible to associate "actions" (e.g. amoxicillin should be prescribed) to "patient conditions" (e.g. patient allergic to penicillin) in different ways: as Medical Logic Modules (MLMs) in Arden Syntax[7], an arborescence of the different clinical situations for a particular disease in Decision trees[8], a graph focusing on patient states in EON[9], or a flowchart of structured steps in GLIF[10].

However, there are two main problems associated with the implementation of CPGs in CDSSs. First, many clinical situations are not described in CPGs and are therefore not considered[11,12]. For instance, in some CPGs , experts give recommendations for uncomplicated cystitis, but not for cystitis in a woman with renal impairment. Second, CPG updating lags behind advances in medical knowledge[13], because updating takes time and it can be difficult to determine when an update is actually required[14]. For instance, in France, general practitioners have continued to prescribe amoxicillin-potassium clavulanate combinations for adult patients with sinusitis, as recommended in the CPGs written in 2005, but the frequency of acquired resistance to amoxicillin in *Haemophilus influenzae* has actually decreased considerably, making it possible to prescribe amoxicillin alone rather than the amoxicillin-potassium clavulanate combination. Physicians did not receive this information until 2011.

It may be possible to overcome these limitations by implementing the medical reasoning used to deduce medical "actions" from patient "conditions", rather than implementing "conditions"-"actions" combinations. In this

approach, the CDSS should be able to retrieve the recommended drugs without expert intervention. For example, for women with cystitis, CPGs recommend fosfomycin trometamol treatment.

(i) The usual approach is based on superficial associative medical reasoning, often involving the implementation of expert conclusions: i.e. the association "woman cystitis → fosfomycin trometamol" (e.g.: "if cystitis in a woman, then prescribe fosfomycin trometamol");

(ii) In our approach, we use a deeper reasoning: we try to implement the arguments used by the experts who wrote the CPGs to recommend one antibiotic, i.e. "In cystitis, the recommended antibiotic should have the following properties: it must be naturally active against *E. coli*, it must reach sufficiently high concentrations in the bladder, it must not be contraindicated in the patient, etc.". By taking these properties into account, the CDSS should be able to deduce that fosfomycin trometamol should be preferred over other choices for women with cystitis.

The use of this deeper medical reasoning should make it possible to retrieve the recommended treatment from patient and disease conditions. This should make it easier to cover a larger number of clinical situations, and should facilitate updating of the knowledge base.

We used the empiric prescription of antibiotics in primary care as a case study. In this domain, it is particularly important to update recommendations frequently, in accordance with advances in medical knowledge (e.g. the frequency of acquired resistance), because of the risk of bacterial resistance emerging[15]. For the testing of our approach, we needed to understand the deeper medical reasoning used by the experts to recommend a particular antibiotic over others in CPGs for a given clinical situation. We carried out a literature review, but found no accurate description of this deeper medical reasoning. However, we hypothesized that such medical reasoning could be extracted from CPGs and formalized.

The goals of our study were:

(i) To extract from CPGs the deeper medical reasoning on which experts based their recommendations concerning the antibiotics suitable for given clinical situations;

(ii) To implement this reasoning by two different methods and then to select the method giving the best automatic retrieval of the antibiotics recommended in CPGs.

We will first describe the two methods for reproducing the deeper medical reasoning of experts. We then present the study design for their evaluation and the results obtained.

Methods

An analysis of CPGs showed that the deeper medical reasoning used by the experts to recommend a particular antibiotic over others in CPGs was based on the use of the antibiotic properties. We began by identifying these properties and then investigated two methods for reproducing the medical reasoning taking these properties into account. Finally, we implemented and tested the two methods.

Extraction of the properties of antibiotics on which expert recommendations are based

We first extracted from the CPGs the properties of antibiotics used by the experts writing these CPGs to argument the recommendation of a particular antibiotic over others .

We analyzed seven CPGs: five were provided by French health authorities, one by the European Society of Clinical Microbiology and Infectious Diseases and one by both the Infectious Diseases Society of America and the European Society of Clinical Microbiology. They concerned 21 clinical situations relating to various diseases (cystitis, pyelonephritis, prostatitis, pharyngitis, otitis, sinusitis and pneumonia). We manually extracted all the expressions linked to the properties of antibiotics used to argument the preference of one antibiotic over others. Similar expressions were then grouped into categories of properties. For example, "natural sensitivity" and "natural activity" were grouped into the category "natural activity".

For each category of properties, we then added a question to determine whether the antibiotic considered displayed the property concerned. For example, the property "natural activity" was associated with the question "Does the antibiotic have sufficient microbiological activity against wild-type strains of the causal bacterium?" The response to the question, obtained from CPGs, was used to determine whether a given antibiotic had the property considered: if the response to the question was "yes" or, "no", then the considered antibiotic was considered to "have" or "not have" the property concerned, respectively, and if the response was "not available", then we considered that there was "no information available".

We then differentiated between:

(i) The "necessary" properties that an antibiotic must have to be usable in a patient, and to treat the infection. These properties ensure that an antibiotic is both safe for the patient, and able to cure the infection. These properties were used to obtain a list of appropriate antibiotics;

(ii) The "preference" properties that an appropriate antibiotic must have for that antibiotic to be preferred from a list of appropriate antibiotics, in a given clinical situation. These properties make it possible to choose one antibiotic through a list of antibiotics that could be prescribed to cure a patient. These properties were used to generate a list of recommended antibiotics.

Use of antibiotic properties to reproduce the deeper medical reasoning used by experts to generate a list of recommended antibiotics

We then tried to reproduce the deeper medical reasoning used by the experts writing CPGs, to generate a list of appropriate and recommended antibiotics, taking into account the properties of these drugs. We investigated two methods.

Constructing a list of appropriate antibiotics

For each clinical situation, we began with an initial list of antibiotics, all of which were potential candidates for recommendation. This initial list of candidate antibiotics differs between clinical situations and corresponds to all antibiotics described for the situation concerned in CPGs.

For each antibiotic on the list, we searched for answers to questions about necessary properties in CPGs. We excluded from the list all antibiotics for which there was at least one "no" or "not available" answer to the questions about necessary properties. The remaining antibiotics were considered to be appropriate.

Generating a list of recommended antibiotics by method 1

Method 1 involved calculating a score expressing the extent to which a particularly antibiotic satisfied the preference properties. The antibiotics with the highest scores were identified as those to be recommended by this method.

For each antibiotic from the list of appropriate antibiotics, we attributed a value according responses to questions about preference properties: if the response to the question was "yes", "no" or "not available", we attributed scores of "1", "-1" or "0", respectively, for the property concerned.

For each appropriate antibiotic, we then calculated the sum of the values attributed for all the preference properties. We retained the antibiotics with the highest scores and discarded the others from the list. The final list obtained with method 1 contained the antibiotics with the highest scores and should correspond to the list of antibiotics recommended in CPGs.

Generating a list of recommended antibiotics by method 2

In method 2, we excluded an antibiotic as soon as a property for preference was not satisfied. The antibiotics remaining in the list after the series of questions depended on the order of the questions in the sequence. The antibiotics remaining in the list, or if none remained, those excluded in response to the last question, were considered to be the recommended antibiotics according to this method.

For each successive question relating to preference properties, we excluded the antibiotic from the list if the answer was "no", but retained the antibiotic in the list if the response to the question was "yes" or "not available".

The list was, thus, progressively reduced after each question. The final list of antibiotics to be recommended corresponded to the antibiotics remaining in the list, or if there were no antibiotics remaining, those excluded by the last question. The final list should correspond to the list of antibiotics recommended in the CPGs.

As the final list depends on the order in which the questions are asked, we tested all possible sequences of questions for the 21 clinical situations, and selected the sequences that retrieved the list of antibiotics recommended in the CPGs for the largest number of clinical situations.

Implementation and evaluation of the two methods for reproducing the deeper medical reasoning used by experts in CPGs

We compared the two methods, by creating a database containing all the clinical situations and antibiotics described in CPGs (34 substances and 11 classes of antibiotics), the properties of which were extracted from CPGs. We implemented both methods in PHP.

We then tested each method as follows. First, for each clinical situation, we established:

- An initial list of candidate antibiotics for the testing of both methods, corresponding to all antibiotics described for the situation in CPGs (about 13 antibiotics per clinical situation);
- A list of the antibiotics recommended in CPGs, which we took as the gold standard.

For each clinical situation, we then applied the method to the initial list of candidate antibiotics and obtained a final list of antibiotics. This final list was then compared with the gold standard. If the final list of antibiotics obtained with the method corresponded exactly to the full list of antibiotics recommended in CPGs, then the method was considered "satisfactory" for the clinical situation.

We then calculated the total number of clinical situations for which the method was considered "satisfactory".

Finally, we compared the numbers of clinical situations for which a "satisfactory" result was obtained between the two methods. The method with the largest number of situations for which a "satisfactory" result was obtained was considered to be the best method for reproducing the deeper medical reasoning of experts for the empiric prescription of antibiotics.

Results

Properties of antibiotics used by the experts to formulate recommendations

Twelve antibiotic properties were retrieved in CPGs, in one or more clinical situations (e.g.: "natural activity" was retrieved for all clinical situations, whereas "availability" was retrieved for only one clinical situation). Two kinds of properties could be distinguished:

(i) "Necessary" properties (A to F, Table 1). Two of these properties related to the use of the antibiotic ("availability", "contraindication"). Four related to its potential efficacy ("natural activity", "likely activity", "concentration", "evidence of clinical efficacy"). Any antibiotic with all six necessary properties was considered "appropriate". For instance, amoxicillin, ampicillin, and penicillin V were all considered appropriate for pharyngitis;

(ii) "Preference" properties (G to L, Table 2). These properties related to the efficacy of the antibiotic ("level of efficacy", "protocol characteristics"), tolerance ("side effects") or ecological risk ("class characteristics", "spectrum of activity", "ecological adverse effects"). For instance, amoxicillin is recommended over ampicillin and penicillin for pharyngitis, because of the characteristics of its treatment protocol (shorter duration of treatment, favoring compliance).

Information about the properties described in CPGs was obtained from various resources:
(a) Results of clinical trials (properties: "evidence of clinical efficacy", "protocol characteristics", "level of efficacy");
(b) Clinical data (property: "contraindication");
(c) Microbiological data (properties: "natural activity", "likely activity", "spectrum of activity");
(c) Pharmacokinetics data (properties: "concentration in the infected organ");
(d) Pharmacovigilance (properties: "side effects");
(e) Drug marketing (property: "availability);
(f) Expert knowledge (properties: "class characteristics", "ecological adverse effects").

Table 1. Necessary properties used in expert medical reasoning as the basis for recommendations concerning antibiotic use. The frequency of use of the properties is the number of clinical situations in which the property is mentioned.

	Property	Questions relating to the property concerned, with examples of responses indicated in italics	Frequency of use (%)
A	Market availability	Is the antibiotic commercially available in the country? *No, pivmecillinam is not available in North America*	1/21 (5)
B	Natural activity against etiologic bacteria	Does the antibiotic have sufficient microbiological activity against wild-type strains of the causal bacterium? *Yes, amoxicillin is naturally active against Streptococcus pyogenes*	21/21 (100)
C	Concentration in the infected organ	Does the antibiotic reach sufficiently high concentration in the infected organ? *No, nitrofurantoin does not reach high concentrations in the kidney*	16/21 (76)
D	Evidence of clinical efficacy	Has clinical efficacy been proven in the clinical situation? *Yes, fluoroquinolones have been shown to be effective for acute pyelonephritis in a randomized controlled trial*	20/21 (95)
E	Likely activity against etiologic bacteria	Is the frequency of acquired resistance to the antibiotic low in the etiologic bacterium? *Yes, the frequency of acquired resistance to amoxicillin in Streptococcus pyogenes is less than 10%*	21/21 (100)
F	Contraindication in the patient	Is the antibiotic not contraindicated in the patient? *No, telithromycin is contraindicated in children under the age of 12 years*	17/21 (81)

Table 2. Preference properties used in the deeper medical reasoning of experts for antibiotic recommendations. The frequency of use of the properties corresponds to the number of clinical situations for which the property is mentioned.

	Property	Questions relating to the properties, with examples of responses given in italics	Frequency of use (%)
G	Protocol characteristics	Does the protocol for the use of the antibiotic favor compliance? *Yes, fosfomycin trometamol is prescribed as a single dose for uncomplicated cystitis*	17/21 (81)
H	Class characteristics	Does the antibiotic belong to a class that is not precious? *No, levofloxacin belongs to a precious class of antibiotics that should be reserved for serious indications*	6/21 (29)
I	Side effects	Is the antibiotic known to have (no serious or no frequent) side effects? *No, cefixime is associated with a high risk of pseudomembranous colitis caused by Clostridium difficile*	13/21 (62)
J	Level of efficacy (high, middle, low)	Is the antibiotic very effective? *Yes ciprofloxacin is highly effective in women with uncomplicated cystitis (clinical cure: 90% [85;98])*	17/21 (81)
K	Activity spectrum	Is the spectrum of activity of the antibiotic narrow? *No, levofloxacin has a broad spectrum of activity*	4/21 (19)
L	Ecological adverse effects	Does the antibiotic have a low risk of collateral damage? *No, first-generation quinolones promote the emergence of bacterial resistance*	14/21 (67)

Number of clinical situations for which a satisfactory result was obtained with each method

Method 1: Attribution of a relative score to antibiotics (illustration, Table 3)

With method 1, we obtained satisfactory results for 16 of a total of 21 situations (Table 4). The five clinical situations for which satisfactory results were not obtained were "uncomplicated pyelonephritis in women", "uncomplicated cystitis in women", "pharyngitis in adults without allergy", "maxillary sinusitis in adults without allergy" and "pneumonia in adults".

Method 2: Exclusion of antibiotics through a sequence of questions (illustration, Figure 1)

Permuting the questions about the six preference properties resulted in 720 sequences of questions (6!=720). We tested all 720 sequences for the 21 clinical situations, and tried to identify the most generic sequences (those giving satisfactory results in the largest number of clinical situations). Ten such sequences were identified:

"G, H, I, J, L, K" / "G, H, J, I, L, K" / "G, I, H, J, L, K"
"H, I, J, G, L, K" / "H, I, G, J, L, K" / "H, G, I, J, L, K" / "H, G, J, I, L, K"
"I, G, H, J, L, K" / "I, H, G, J, L, K" / "I, H, J, G, L, K"

The qualitative analysis of the 10 sequences showed that:

- In the 1st and 2nd positions of the sequence, we always found questions relating to properties "G" (Protocol characteristics), "H" (Class characteristics) or "I" (Side effects);
- In the 3rd position of the sequence, we always found questions relating to the properties "G" (Protocol characteristics), "H" (Class characteristics), "I" (Side effects) or "J" (Level of efficacy);
- In the 4th position of the sequence, we always found questions about property "G" (Protocol characteristics), "I" (Side effects) or "J" (Level of efficacy);
- In the 5th position of the sequence, we always found questions about property "L" (Ecological adverse effects);
- In the 6th position of the sequence, we always found questions about property "K" (Activity spectrum).

Method 2 gave a satisfactory response in 20 of the 21 clinical situations (Table 4), for these 10 sequences of questions. The only clinical situation for which a satisfactory result was not obtained was "uncomplicated cystitis in women".

Table 3. Method 1 – Attributing a relative score to antibiotics. (See the correspondence of properties A to L in Tables 1 and 2). Example of seven antibiotics, for pharyngitis in adults with penicillin allergy and without a contraindication for beta-lactams. All seven antibiotics were present in the initial list of candidate antibiotics. Two antibiotics did not have all the necessary properties, and were therefore excluded from the list ("amoxicillin" for property F, and "azithromycin" for property E). The five remaining antibiotics were considered appropriate. For each of these antibiotics, we attributed a relative value to each preference property. The sum of these values was maximal for three antibiotics ("cefuroxime axetil', "cefotiam hexetil", and "cefpodoxime proxetil"), which were therefore considered to be recommended by method 1. As they corresponded to the gold standard (i.e. the list of antibiotics recommended in CPGs), method 1 was considered "satisfactory" for this clinical situation.

	Necessary properties Responses to questions *(Y: Yes, N: No)*						**Preference properties** Attribution of a score						**Sum for G to L**	**Conclusion**
	A	**B**	**C**	**D**	**E**	**F**	**G**	**H**	**I**	**J**	**K**	**L**		
Amoxicillin	Y	Y	Y	Y	Y	N	-	-	-	-	-	-	-	Inappropriate
Azithromycin	Y	Y	Y	Y	N	Y	-	-	-	-	-	-	-	Inappropriate
Cefaclor	Y	Y	Y	Y	Y	Y	-1	0	0	0	0	-1	-2	Appropriate
Cefuroxime axetil	Y	Y	Y	Y	Y	Y	1	0	0	0	0	-1	**0**	Recommended
Cefotiam hexetil	Y	Y	Y	Y	Y	Y	1	0	0	0	0	-1	**0**	Recommended
Cefpodoxime proxetil	Y	Y	Y	Y	Y	Y	1	0	0	0	0	-1	**0**	Recommended
Pristinamycin	Y	Y	Y	Y	Y	Y	0	0	0	-1	0	0	-1	Appropriate

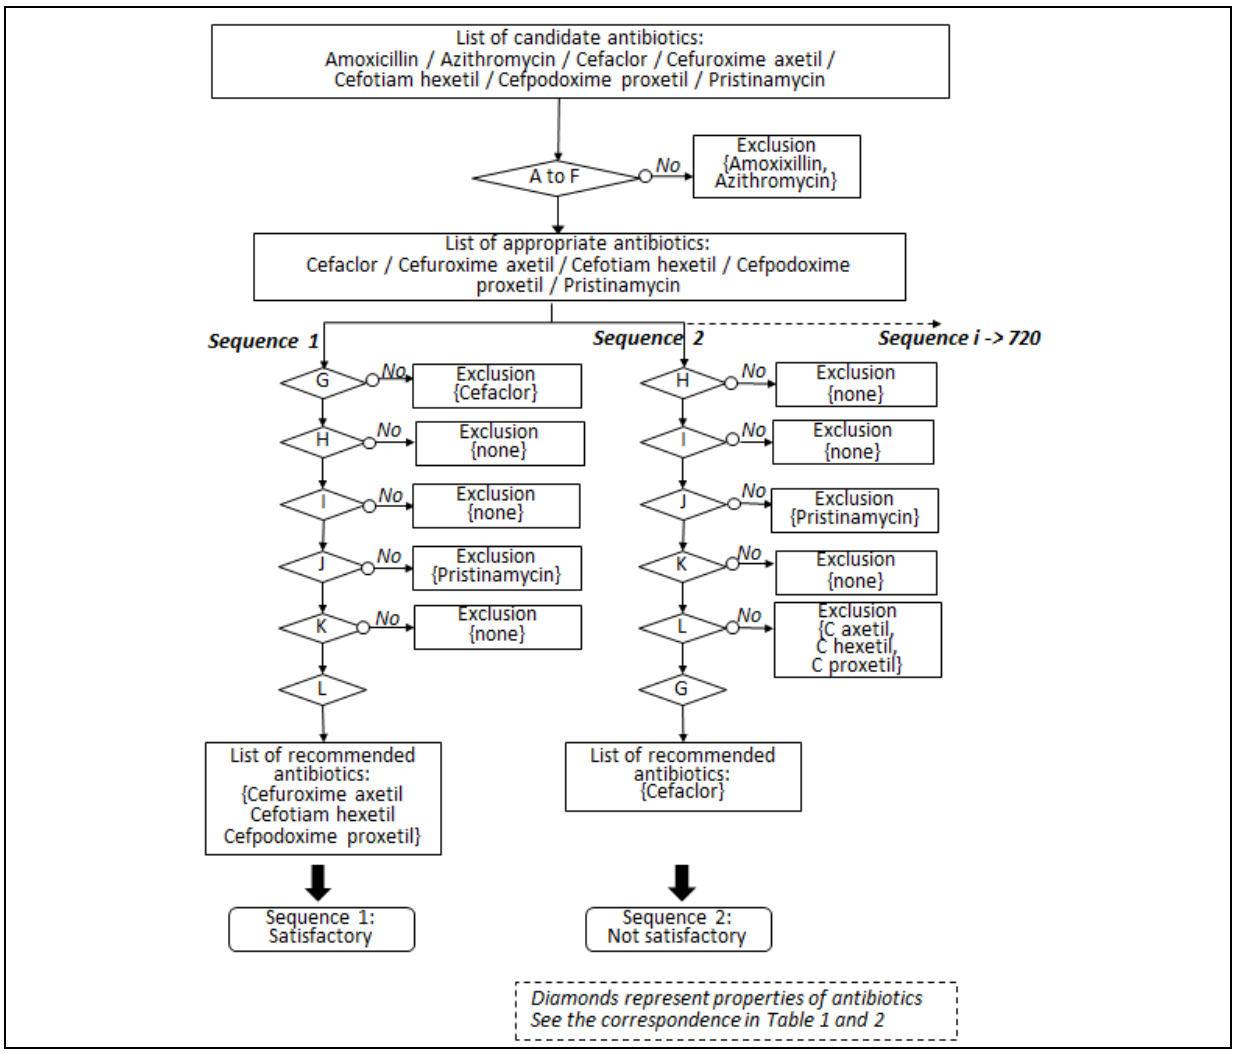

Figure 1. Method 2 – Exclusion of antibiotics according to a sequence of questions (see the correspondence of properties A to L in Tables 1 and 2). Example of seven antibiotics, for pharyngitis in adults with penicillin allergy and without a contraindication for beta-lactams. All seven antibiotics were present in the initial list of candidate antibiotics. Two antibiotics did not have all the necessary properties and were excluded from the list ("amoxicillin" for property F, and "azithromycin" for property E). The other five antibiotics were considered appropriate. For the six preference properties, 720 sequences of questions are possible by permutation of the properties. The final list of antibiotics obtained depends on the order of questions in the sequence. We illustrate the results for two sequences: sequence 1 generated a list of three antibiotics ("cefuroxime axetil', "cefotiam hexetil", and "cefpodoxime proxetil"), whereas sequence 2 yielded one antibiotic ("cefaclor"). As the list obtained with sequence 1 corresponds to the gold standard (i.e. the list of antibiotics recommended in CPGs), sequence 1 of method 2 is considered "satisfactory" for this clinical situation, whereas sequence 2 is not.

Table 4. Comparison of methods 1 and 2. Method 2 gives satisfactory results for a larger number of clinical situations than method 1.

	Method 1 – Attribution of a relative score to antibiotics	Method 2 – Exclusion of antibiotics through a sequence of questions
Number of clinical situations for which the result was considered "satisfactory"	16	20
Number of clinical situations for which the result was considered "not satisfactory"	5	1
Total	21	21

Discussion and Conclusion

We extracted the deeper medical reasoning underlying the CPGs, from the arguments used by the experts formulating recommendations concerning antibiotic use. We used this reasoning in two ways: "attribution of a relative score to antibiotics" and "exclusion of antibiotics through a sequence of questions". The "exclusion" method reproduced expert reasoning more accurately, as it retrieved the full list of recommended antibiotics for nearly all clinical situations (20 clinical situations, versus 16 for the "scoring" method). Furthermore, the only situation for which the "exclusion" method did not give a satisfactory result (uncomplicated cystitis) cannot really be considered a failure. In this situation, the experts produced a CPG that can be divided into several nation-specific recommendations, with a broad list of antibiotics that could be recommended in various countries, the final choice depending on local levels of acquired resistance. We gave equal weighting to all the properties of antibiotics considered. This approach yielded a highly satisfactory score, and we would have been unlikely to obtain a better result by weighting the properties differently.

Our approach is different from that of MYCIN[1] because (i) we used the arguments of a group of experts based on evidence-based medicine rather than the knowledge of a single expert; (ii) our method did not require interaction with the clinician; (iii) our method is simple and can generate recommendations very rapidly; (iv) our method can provide clinicians with an overview of the deeper medical reasoning underlying recommendations. This is not the case for MYCIN, for which the underlying reasoning is too complex to be presented in full to clinicians.

Our approach can be used to design a CDSS reproducing the deeper medical reasoning used by the experts writing CPGs. CDSSs generally implement the conclusions of the medical reasoning, i.e. the "actions" recommended for a particular clinical situation (e.g.: "*Amoxicillin is recommended for childhood pharyngitis*"). In our approach, we tried to implement the arguments underpinning the reasoning behind the recommendation, to make it possible to deduce the recommended antibiotics automatically (e.g.: "*for prescription for childhood pharyngitis, an antibiotic should have properties A to F, then, successively, properties G, H, I, J, L and K (see the correspondence in table 1 and 2)*"). The implementation of deeper medical reasoning, rather than its conclusions, has several advantages:
Recommendations can be justified and explained to physicians. As the deeper medical reasoning is based on the properties of the antibiotics, it can easily be understood by physicians. For example, a physician can easily understand that an antibiotic that has proved to be clinical effective and well tolerated by patients is preferred over an antibiotic that is effective but poorly tolerated. The provision of convincing and understandable explanations to physicians should increase their confidence in the CDSS, increasing the chances of its adoption[16]. Such explanations also help to provide physicians with up-to-date knowledge[17] and to develop their critical analysis capacities[17].
Recommendations may be easier to update. As the deeper medical reasoning is separate from the knowledge base containing the properties of antibiotics, it should be easier to update recommendations, and this process should be instantaneous[18]. The properties of antibiotics could be updated through various resources. For example, microbiological properties ("natural activity", "likely activity"; "activity spectrum") could be extracted from microbiological observatories. Properties relating to clinical data ("contraindication"), pharmacokinetics ("concentration"), or market availability ("availability") could be recuperated from drug databases[19]. The "side effects" property could be updated from pharmacovigilance databases. Properties relating to expert knowledge ("class characteristics", "ecological adverse effects") could be extracted from reference sources in infectious diseases. Similarly, evidence-based properties ("evidence of clinical efficacy", "protocol characteristics", "level of

efficacy") could be extracted from previous publications (e.g.: Medline). The incorporation of evidence-based medicine into CDSSs can considerably improve healthcare quality[14,20].

Recommendations could be given for clinical situations not described in CPGs. For example, the clinical situations described in CPGs for pharyngitis are: {adult; child < 6; child 6-12; child > 12} AND {without beta-lactam allergy; with penicillin allergy without cephalosporin contraindication; with beta-lactam contraindication}. The clinical situation "pharyngitis in pregnant women" is not described. With our approach, the system could deduce the antibiotics that should be recommended, by excluding all antibiotics contraindicated in pregnant women. Furthermore, the list of appropriate antibiotics could be used by physicians when they do not wish to prescribe the recommended antibiotics. For example, in uncomplicated cystitis in women, if the physician prefers not to prescribe the recommended antibiotic (fosfomycin trometamol) because it has been poorly tolerated by the patient in the past, he or she can select an alternative from the list of appropriate antibiotics. The provision of recommendations that can be adjusted to any clinical situation is likely to increase the compliance of physicians with recommendations[21].

This work now needs to be taken forward in several ways:

Confirmation of the robustness of our approach by expanding the evaluation to other clinical situations and to all the antibiotics available on the market. Both methods were assessed for urinary and respiratory infections, and only for the antibiotics described in CPGs. These methods should now be tested in other clinical situations (e.g. sexually transmitted infections, clinical situations specific to hospitals, etc.) and for all the antibiotics available on the market.

Confirmation of the validity of the recommendations generated by this method for clinical situations not described in CPGs, and for the updating of CPGs. Our approach was tested only for clinical situations described in CPGs, and not for other clinical situations. It will be necessary to test this method for clinical situations not described in CPGs, by taking the opinions of experts specializing in antibiotic treatment as the gold standard (because these situations are not described in CPGs).

Checking of the completeness of the list of the properties of the antibiotics identified in CPGs. We extracted, from CPGs, the properties of antibiotics most important for medical reasoning. It would be useful to collect the opinions of clinicians specialized in the domain of infectious diseases, to ensure that this list is complete.

Evaluation of the extent to which our approach could be extrapolated to other medical domains. The use of a deeper reasoning based on the arguments of the experts writing in CPGs, is particularly appropriate in the domain of antibiotic treatment, because arguments are explicit and related to the properties of drugs, including patient safety (contraindication), efficacy for curing the disease, and pharmaceutical properties (e.g. side effects). In other domains, other arguments would probably need to be taken into account, relating to temporal reasoning in chronic diseases, or to combinations of drugs. The possible extrapolation of this approach to other medical domains should therefore be investigated.

In conclusion, we propose a method for reproducing the deeper medical reasoning used by experts drawing up CPGs and underpinning the arguments used to justify the choices made. The robustness of this method should be assessed in a larger study before its implementation in a CDSS[22,23], to assist physicians in the empiric prescription of antibiotics in primary care. This CDSS will be assessed in clinical practice.

Patient-Centered Appointment Scheduling Using Agent-Based Simulation

Ayten Turkcan[1], PhD, Tammy Toscos, PhD[2], Brad N. Doebbeling, MD, MSc[3]

Abstract

Enhanced access and continuity are key components of patient-centered care. Existing studies show that several interventions such as providing same day appointments, walk-in services, after-hours care, and group appointments, have been used to redesign the healthcare systems for improved access to primary care. However, an intervention focusing on a single component of care delivery (i.e. improving access to acute care) might have a negative impact other components of the system (i.e. reduced continuity of care for chronic patients). Therefore, primary care clinics should consider implementing multiple interventions tailored for their patient population needs. We collected rapid ethnography and observations to better understand clinic workflow and key constraints. We then developed an agent-based simulation model that includes all access modalities (appointments, walk-ins, and after-hours access), incorporate resources and key constraints and determine the best appointment scheduling method that improves access and continuity of care. This paper demonstrates the value of simulation models to test a variety of alternative strategies to improve access to care through scheduling.

Introduction

Primary care clinics are under great pressure to improve access, health outcomes, quality and efficiency of care with limited availability of resources, especially in the current funding environment. The importance of providing patient-centered care with enhanced access and continuity has been emphasized in several studies.[1, 2] Interventions that vary according to the domain of care (acute care, preventive care, or chronic care) have been used to enhance primary care[3]. Same-day appointments, telephone triaging, walk-in centers, and after-hour services are used to improve access to acute care.[3] Multidisciplinary care teams, disease specific clinics, group appointments, registries, information and decision support systems, patient education and workforce development are used to improve access to care for chronic disease.[3] Community and population based programs to increase awareness, support systems for compliance and reminder systems are used to improve access to preventive care.[3] However, interventions that focus on a single component of care delivery are shown to have negative or no effect on other components of the system. For example, one study identified challenges in securing ongoing appointments for chronic care patients, due to increased availability of same-day appointments for acute care.[4] Another study evaluated the introduction of walk-in primary care clinic and reported good use by patients; however, there was no reduction in use of pre-existing services.[5] In another study, after-hours service did not show improvement in access to after-hours care, due to misconceptions about how to access the new system.[6] Therefore, multiple strategies targeting different levels or components of the health care system should be used to achieve the best performance.[3]

There are several access barriers to care including financial and non-financial barriers. While financial access barriers were found to be a primary problem experienced by 18% of US adults surveyed, 21% experienced non-financial barriers that led to unmet needs or delayed care[7]. The most commonly cited non-financial barrier was accommodation (challenges making appointments and ability to see a provider during limited hours)[8]. A systematic literature review revealed challenges for patients in obtaining appointments, longer waiting times, short business hours at the primary care clinics, unavailability of a regular physician or clinic, and low socioeconomic status to be associated with inappropriate use of emergency services.[9] Effective scheduling could address accommodation barriers; however, health centers struggle to implement novel scheduling methods due to lack of decision support tools that can be used to determine the best scheduling method tailored according to the patient population needs[10]. The number of strategies in the literature, the conflicting results of the existing studies, and the limited clinic resources make it difficult for clinic managers to determine the best set of interventions for their patient population and setting. In a recent study, two-thirds of the surveyed safety-net health centers did not have a process for same-day scheduling or had a process that needed improvement.[1] The aim of this study is to model the patient population

and primary care delivery system using simulation and then use the resultant model to determine optimal scheduling methods for improved access to care and continuity of care.

Background

In a project involving four community health centers (CHCs) in Indiana, we identified several challenges for patients in obtaining appointments including long waiting times, short business hours at the primary care clinics, and unavailability of a regular physician or clinic. The most commonly used scheduling method observed was a hybrid of traditional and advanced access scheduling. Patients with perceived need for routine follow-up (e.g. chronic conditions, routine visits for prenatal and well child check, and lab tests) are often scheduled in advance with a lead-time of 2 weeks to 9 months, depending on the condition, clinic, and provider. All clinics had adopted one or more strategies to provide some same-day access for acute care. Triage appointments (a number of appointment slots are kept open for acute problems) and walk-in hours are the strategies used to provide same-day access for acute demand. Overbooking was allowed by permission of the providers or, in urgent cases, patients were referred to local emergency rooms for care. Open access scheduling was used in one clinic where 80% of the appointments were kept open for same-day access. If a patient cannot be scheduled on the same day, he/she was asked to call back next day. Another clinic had a nurse practitioner (NP) whose schedule was explicitly kept open to provide same-day access to patients with acute care needs. Some clinics had walk-in hours on certain evenings and/or on Saturdays for established patients; an effective way of providing care at more convenient times for working patients.

Patient no-show was a major challenge for all clinics. Missed appointments reduce the continuity of care for no-show patients, reduce timely access to care for patients who cannot get an appointment, waste provider resources and can negatively impact health outcomes. While appointment reminders are often used to reduce no-shows, the missed-appointment rates were still higher than desired, about 25% for the clinics using traditional scheduling with triage appointments. No-shows worsen as the length of time between making the appointment and the actual visit date increased.

Implementation of open access scheduling may hold considerable potential in clinics where there is a high rate of patients who end-up going to emergency departments, even for non-urgent problems, because they cannot get a same-day appointment. The successful implementation of advanced access scheduling is reported to reduce no-shows, improve provider utilization and patient satisfaction. However, successful implementation requires careful analysis of clinic capacity and patient demand. Inappropriate proportions of capacity allocated for open access typically causes mismatch between capacity and demand, and result in implementation failure.[11] In our study, we noted that open access scheduling faces resistance from providers and staff due to uncertainties regarding its implementation and how it would actually work.

Previous studies have cited several reasons for no-shows including patient-related factors, scheduling system problems, and environmental and financial factors. Several interventions including appointment reminders, patient education, follow-up after a missed appointment, and open access scheduling have been used to reduce no-shows.[12] However, no-shows could not be eliminated completely due to several factors. We developed a logistic regression model that includes age, lead time (time between the appointment is made and the actual appointment time), prior no-show behavior, provider type, insurance type, and appointment type, as predictors of patient no-show.[12] Most of the existing literature ends with reporting the predictors of no-shows. Here, our aim is to use no-show prediction models to estimate actual demand and develop advanced scheduling methods considering individual no-show probabilities.

Many studies in the operations research literature propose appointment scheduling methods with the goal of improving clinic accessibility and efficiency. Cayirli and Veral[13] provided an extensive literature review with eighty papers in 2003. Since 2003, more than 300 papers cited the literature review paper of Cayirli and Veral[13], showing the significant growth of research on appointment scheduling. Existing studies consider appointment scheduling in different settings including primary care, specialty care and surgical departments. Most of the appointment scheduling studies focus on single stage, single resource environments (i.e. primary care or specialty care where only doctor appointments are considered). Earlier analytical studies used queuing theory and mathematical programming methods with simplifying assumptions to determine appointment schedules[13]. Most of the analytical studies could not be validated in real environments due to unrealistic assumptions. Simulation studies included

complex environmental factors such as unpunctuality, no-shows, walk-ins, etc. to find the best appointment scheduling rule. However, these studies were not easily implementable in other environments due to extensive data collection requirements. In recent years, analytical studies made more realistic assumptions including no-shows, cancellations, walk-ins, different patient types, priorities, and preferences. However, these advanced scheduling methods are rarely applied in clinical practice. In response to this gap, we sought to develop a simulation based tool that can be used in clinics to determine the best scheduling policy tailored to their patient population needs.

Over the past two decades, modeling and simulation have come of age as tools to help teams and managers support different cognitive and group processes. Simulation has been widely used in modeling health care systems in several settings, including outpatient departments.[14] Most health care simulation applications in the literature aim to provide better operational decision-making and planning tools.[15, 16] Simulation studies that model outpatient clinics focus on scheduling and capacity planning. Most of the studies model patient flow within the clinic and analyze the impact of scheduling methods on in-clinic patient waiting times and provider idle times.[16] However, the waiting time for an appointment (time between the time appointment is scheduled and actual appointment time) is also very important for clinics aiming to provide timely access to care.[10, 16] In this study, we focus on scheduling practices that directly accommodate the needs of patients while still meeting the efficiency needs of the CHCs and providers. We use agent-based simulation to model the care delivery system to incorporate population characteristics, care needs (demand), and common services provided within the health care system.[17]

Methods

We use simulation modeling, an operations research method, to model the scheduling process for provider appointments in CHCs. Rapid ethnography and observations are the key approaches used to understand the scheduling process and collect data for the simulation model. Rapid ethnography is a collection of methods used to understand the activities of users given significant time pressures and limited time in the field. The core elements of rapid ethnography include limiting or constraining the research focus and scope, using key informants, capturing rich field data by using multiple observers and interactive observation techniques, and collaborative qualitative data analysis.[18] For rapid ethnography and observations, we identify key informants including: 1) call center (or telephone room) and front office personnel as they relate to patient contact and scheduling, 2) enrollment specialists as they relate to new patients, 3) triage nurses as they relate to scheduling of acute appointments, and 4) quality assurance/information technology (QA/IT) personnel as they relate to the retrieval of appointment scheduling and provider capacity data. A team of two project members conducted interviews and obtained workflow summaries, policies, procedures, and artifacts used in the clinics. Based on the interviews performed, workflow diagrams are developed and then verified by the key informants. The simulation model is used to identify the impact of different scheduling and resource allocation strategies on key performance measures such as patient waiting times, provider productivity, patient no-shows, and continuity of care. The modeling tool is designed to be flexible so that it can be used by several clinics. The flexibility is achieved using input data files and graphical user interface. The inputs to the simulation model are:

- Provider capacity (capacity allocated for walk-ins, acute, non-acute and follow-up appointments)
- Patient population characteristics (age, gender, insurance, health status)
- Patient demand for care (demand for acute, non-acute and follow-up appointments)
- Scheduling method (traditional scheduling with triage appointments and open access scheduling)
- Scheduling horizon for each appointment type (acute, non-acute, follow-up)
- Maximum panel size for each provider

A data collection tool is developed to collect provider capacity, patient population characteristics, patient demand, no-show and cancellation data. The required variables are determined together with the QA/IT personnel, who retrieved the data from the electronic medical record system and sent the data for further analysis. The patient population characteristics including age, gender, insurance, and health status are provided as percentages with respect to the total number of patients. The provider template schedules are used to fill out the provider capacity data. The average number of annual visits per patient, no-shows and cancellations are calculated according to the appointment scheduling data provided by the QA/IT person. The data analysis results are discussed with the QA/IT personnel, COO and CEO of each clinic to validate the input data for the simulation model.

Figure 1 shows the general structure of the simulation model where the simulation model is initialized with clinic specific data (i.e. provider capacity and patient population characteristics), patient demand for care is generated

based on care needs of the patient population, and appointments are scheduled according to provider availability, capacity allocated for each appointment type, and appointment scheduling method.

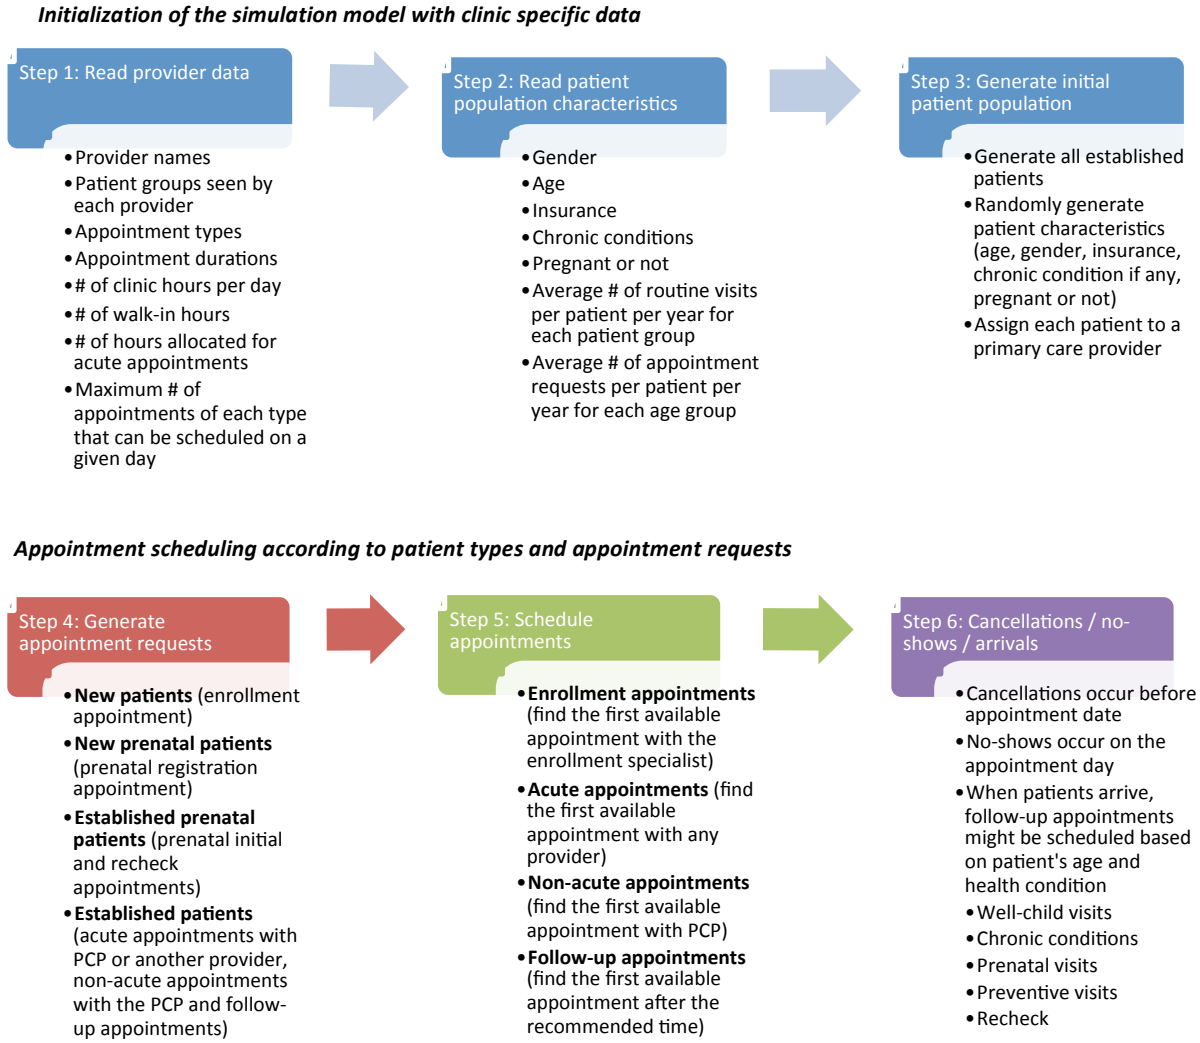

Figure 1. Simulation model

The simulation model starts with reading the provider and patient population data from an Excel file (Steps 1 and 2) and generating the initial patient population based on the number of unique patients served by the clinic (Step 3). Age, gender, insurance, and health condition (pregnancy and chronic condition) of each patient is generated based on patient demographics data. Each patient is assigned to a primary care provider based on available provider capacity and maximum panel size. The next step is generating the appointment requests for each patient (Step 4). We divided the patients into four groups based on their needs for different appointment types and resources. Once an appointment is requested, the appointment type (i.e. new, acute, routine, complex, well-child, newborn, etc.) is determined and scheduled according to patient type, resource availability, type of appointment request, and the scheduling policy used in the clinic (i.e. traditional approach with triage appointments, open-access scheduling) (Step 5). We included cancellations, arrivals and no-shows in our simulation model to calculate the access, operational, and quality measures (Step 6).

Initialization of the simulation model with clinic specific data

Step 1: The provider data required for the simulation model includes provider names, patient groups seen by each provider (i.e. pediatrics, adult, family medicine, women), number of working hours per day, number of hours allocated for acute/same-day appointments, appointment durations, and maximum number of appointments that can be scheduled. The providers allocate different durations for different types of appointments. For example, a provider might allocate 30-minute appointments for new and chronic patients, and 15-minute appointments for acute patients. The providers might have a different working schedule during the week. There might be restrictions on the number of appointments that can be scheduled on a given day (i.e. only two new patient appointments per day). An Excel file is prepared with the required information and the QA/IT person filled out that information by using the providers' template schedules. Tables 1 and 2 show sample provider data.

Table 1 – Appointment types and durations in minutes for each provider (sample data – does not include all possible appointment types)

Provider no	Providers	Patient group	New	Acute	Physical	Chronic/ complex	Well-child	Routine
1	MD1	Pediatrics	15	15	0	15	15	15
2	MD2	Adult	15	15	15	30		15
3	NP2	Adult	30	30	15	30		15
4	MD3	Women	45	30	45	45		30
5	NP2	Family medicine	30	15	30	30	30	30
6	MD4	Family medicine	30	15	15	30	15	15

Table 2 – Available provider capacity, number of hours allocated for same-day appointments, and maximum number of appointments of each type that can be scheduled on a given day (sample data – does not include all possible appointment types)

Providers	Day	Number of clinic hours	Number of walk-in hours	Number of hours allocated for acute	Number of hours allocated for non-acute	Maximum number of appointments that can be scheduled			
						New	Acute	Well child	Routine
MD1	Mon	7	4		3	2		11	
MD1	Wed	7		2	5	2		11	
MD1	Thu	7	4		3	2		11	
MD1	Fri	7		2	5	2		11	
MD2	Mon	7		2	5				
MD2	Tue	7		1	6				
MD2	Wed	7		1	6				
MD2	Thu	7		1	6				
MD2	Fri	7		2	5				

Steps 2-3: In operations research literature, simulation models, which consider modeling of care processes, patient flows and available resources, use historical data to express the demand in terms of a probability distribution function of the quantity or arrival time. In economic studies, which aim to evaluate the economic impact of diseases and health policies, demand is expressed as a function of prices, supplies, age, education, etc.[19-21] As Charfeddine and Montreuil[22] mentioned, demand for healthcare can be expressed in a better way through stochastic modeling of disease progression of each person in a patient population. Even though clinical studies model the disease progression and health status, their focus is to analyze the impact of medical interventions rather than determining the demand[23]. Healthcare demand is a function of multiple factors such as population characteristics, patient health status, treatment guidelines, adherence behavior, etc. We assume age, gender, insurance, and patient's condition

(chronic conditions, pregnancy) are predictors of number of visits. For example, the frequency and number of well-child visits change according to the age of patient. The frequency of prenatal visits change according to the stage of pregnancy. The number of routine visits change according to the health status of patients with chronic conditions. Agent-based simulation models can incorporate all these factors using agents (patient, provider, scheduler, etc.) to provide more realistic estimates of the care needs (e.g., regular provider visits, acute care visits). In the simulation model, we represent each patient as an agent. The simulation model generates the initial set of established patients at the initialization phase. The number of established patients is equal to the unique patients seen in the clinic in one year. The characteristics of each patient are generated based on initial patient demographics data. When the initial patient population is generated, each patient is assigned to a primary care provider (PCP).

Appointment scheduling according to patient types and appointment requests

Step 4: We divided patients into four groups according to two factors (new or established, and prenatal or not) due to the need for different appointment types and resources as shown in Figure 1. Once an appointment is requested, the appointment type (i.e. new, acute, routine, complex, well-child, newborn, etc.) is determined and scheduled according to resource availability, type of appointment request, and the scheduling policy used in the clinic. Figure 2 shows the overall summary of the scheduling process based on appointment types. This flowchart is prepared based on the workflow diagrams developed for the scheduling process through the key informant interviews.

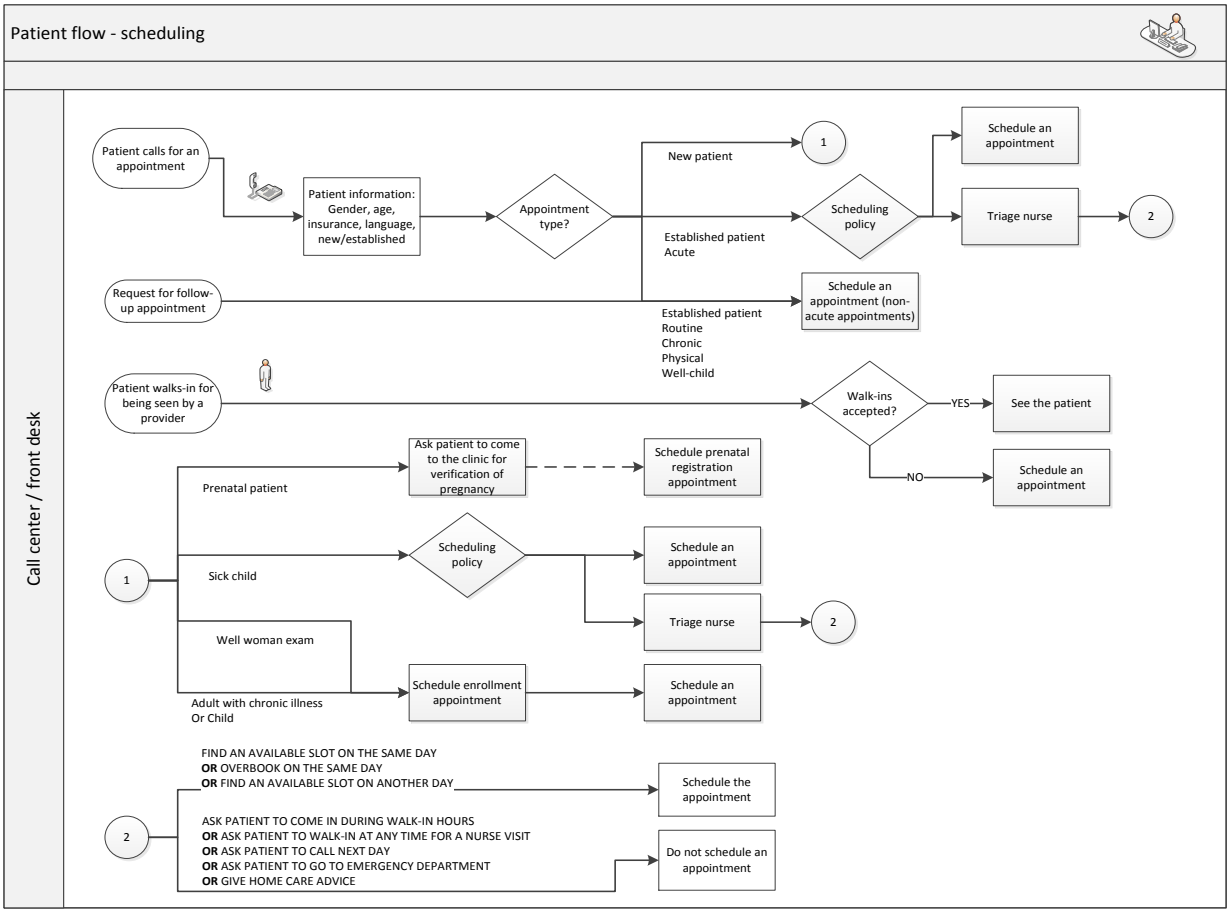

Figure 2 – Flowchart scheduling process according to appointment type and scheduling method.

Step 5: In the simulation model, we considered two types of scheduling methods (traditional scheduling with triage appointments, and open access scheduling). New patients should be scheduled for an enrollment appointment before an appointment can be scheduled with a provider. In traditional scheduling, acute appointments are scheduled on the same day or a few days in advance of triage appointment slots. Non-acute appointments and follow-up appointments

are scheduled to other slots several days in advance. In open access scheduling, most of the appointment slots are open for acute and non-acute appointments and can only be scheduled on the same day (or within a few days in advance). Follow-up appointments can be scheduled several days in advance, but the slots allocated for these appointments are limited. We used different objectives for scheduling of acute, non-acute and follow-up appointments. For acute appointments, our main objective was to minimize patient waiting time. Therefore, the available slots of PCP and other providers are searched to find an appointment time as soon as possible. For non-acute appointments, we sought to maximize continuity of care and minimize patient waiting time. Therefore, we first searched the PCP schedule and then other providers' schedules to find an available slot with a reasonable waiting time. For follow-up appointments, we maximized continuity of care by scheduling the appointment with the PCP.

Step 6: We included cancellations, arrivals and no-shows in our simulation model to determine the actual number of visits. Based on our prior research and existing literature[12, 24, 25], we assumed that the no-show probability is a function of age, insurance, lead time and patient's previous no-show behavior. In the simulation model, we used the regression equation that is determined based on clinic data to calculate the no-show probabilities. We would like to note that even though age, insurance and previous attendance rates cannot be controlled, they can be used to determine the no-show rate for each individual patient. The lead time can be controlled by changing the scheduling horizon (threshold for lead time) for each type of appointment. In our simulation model, scheduling horizon was an input parameter that could be controlled by the user or that determined by the model to minimize no-show rates and maximize continuity of care.

Results

We collected data from the clinics to validate the simulation model based on current practice in the clinics. Since an agent-based simulation model is used with several assumptions related to estimation of no-shows and cancellations, the validation of the input data is important. We compared the number of appointment requests, no-shows, cancellations, and provider utilizations of the simulation model with actual data to make sure that the demand was generated correctly. The simulation model was able to generate appointment requests, no-shows, cancellations and number of visits that were close to the observed data. For example, the average number of visits per week was 573 for the 2-week data provided by one clinic and the simulation model generated an average of 557 visits per week over a 5-year simulation run. The waiting times, percentage of appointments with the PCP, and no-show rates are used as performance measures since they are related to access and continuity of care. Table 3 shows a sample comparison between two scheduling methods. The waiting times for appointments are reduced in open access scheduling. The continuity of care did not change much. The no-show rates are reduced for non-acute appointments due to lower waiting times.

Table 3 – Comparison of traditional and open access scheduling methods

Performance measure	Traditional scheduling with triage appointments Planning horizon: (30, 90, 180)	Open access scheduling Planning horizon: (2,5,180)
Waiting time for acute appointments	Average: 0.5 day Std. dev.: 0.8 day	Average: 0.8 day Std. dev.: 0.4 day
Waiting time for non-acute appointments	Average: 51 days Std. dev.: 38 days	Average: 0.8 day Std. dev.: 0.4 day
Waiting time for follow-up appointments	Average: 48 days Std. dev.: 25 days	Average: 1 day Std. dev.: 1.2 days
Continuity of care (non-acute)	66%	65%
Continuity of care (acute)	57%	60%
No-show percentage (non-acute and follow-up)	23%	10%
No-show percentage (acute)	10%	9.6%

In this study, we could not perform statistical analysis for comparing and validating the simulation model, because the real data was not available for a longer time period. However, we are planning to address this issue in the

continuation of this project, which includes collection of 2-year appointment data from the clinics. We are also planning to use expert opinion for the validation of the simulation results.

Limitations

The proposed simulation model is developed based on current practice in two clinics that use traditional scheduling method. When open access scheduling is chosen, the simulation model reduces the no-show rates due to shorter waiting times. But the simulation model assumes that the patients will continue requesting appointments at the same rate. That is why more visits are scheduled and more arrivals occur when open access scheduling method is used. We believe the behavior of providers and patients will change when open access scheduling is implemented. For example, the providers may not ask the patient to schedule a follow-up appointment after the clinic visit unless it is really necessary. Due to limited number of follow-up appointment slots, the provider might ask the patient to come for a visit in 3-months. But the patient might forget to call to make the next appointment when 3-months pass. These two factors would reduce the number of appointment requests unless the clinics do not implement other interventions such as using provider and patient reminders to schedule the next appointment when the appropriate time comes. Currently, the simulation model does not incorporate these possible changes in behavior. As we develop this model further, we will work with clinics that implemented open access scheduling to be able to include the change in demand.

Next Steps

We are building upon this work with funding from Patient-Centered Outcomes Research Institute (PCORI). We will work with seven CHCs in Indiana to incorporate patients' perspectives to improve access to care for underserved populations. We will conduct rapid ethnography and workflow observation and modeling to identify the current barriers to access and use quantitative approaches to predict no-shows and determine the best scheduling policies that are determined based on patient population characteristics and available provider capacity. In that 3-year project, we will work with the clinics and further develop the proposed simulation model to include workflow and use the model and expert and patient panels to optimally determine the patient-centered interventions tailored for each clinic's patient population.

Conclusions

We used agent-based simulation to model the patient flow and appointment scheduling process in community health centers. The simulation model was designed to be flexible in terms of usability by different clinics. The inputs are entered through Excel files or graphical user interface, which makes the model useful for any clinic. This paper demonstrates the value of simulation models to test a variety of alternative strategies to improve access to care through scheduling.

Acknowledgments

This project was funded by MDwise, an Indiana not-for-profit health insurance company. We greatly appreciate our partnerships with CHCs, their management, staff, providers and patients in conducting this research. We also would like to acknowledge the funding received from Patient-Centered Outcomes Research Institute (PCORI) to develop patient-centered approaches to improve access to care for underserved populations.

Confidence and Information Access in Clinical Decision-Making: An Examination of the Cognitive Processes that affect the Information-seeking Behavior of Physicians

Raymonde Charles Uy, MD, MBA[1], Raymond Francis Sarmiento, MD[1], Alex Gavino, MD[1], Paul Fontelo, MD, MPH[1]
[1]National Library of Medicine, Bethesda, MD 20894

Abstract

Clinical decision-making involves the interplay between cognitive processes and physicians' perceptions of confidence in the context of their information-seeking behavior. The objectives of the study are: to examine how these concepts interact, to determine whether physician confidence, defined in relation to information need, affects clinical decision-making, and if information access improves decision accuracy. We analyzed previously collected data about resident physicians' perceptions of information need from a study comparing abstracts and full-text articles in clinical decision accuracy. We found that there is a significant relation between confidence and accuracy (φ=0.164, $p<0.01$). We also found various differences in the alignment of confidence and accuracy, demonstrating the concepts of underconfidence and overconfidence across years of clinical experience. Access to online literature also has a significant effect on accuracy ($p<0.001$). These results highlight possible CDSS strategies to reduce medical errors.

Introduction

Physicians are faced with many clinical decisions of varying complexity in their everyday practice. Most of these decisions revolve around questions on the diagnosis and therapeutic management of patients. The frequency of clinical questions varies from 0.16 to 1.27 per patient[1], depending on specialty, and up to 5 questions in the inpatient setting[2]. In the process of decision-making, physicians generally use their 'accumulated clinical knowledge', defined as a physician's personal knowledge base accumulated through years of formal education, medical training, research and clinical experience,[3, 4] to answer clinical questions. Accumulated clinical knowledge is traditionally used by physicians as it is the most convenient resource of information in the healthcare setting. This is especially highlighted in critical situations, such as the emergency department where there may be an immediate need for a diagnosis and management. However, reliance on this knowledge alone may lead to medical errors when these clinical questions remain unanswered or unsupported by more recent medical literature.

More physicians are integrating evidence-based medicine in their clinical practice. The conscientious, explicit and judicious use of current best evidence in clinical decision-making is the fundamental principle in the practice of evidence-based medicine (EBM)[5]. However, physicians are faced with numerous challenges that prevent the utilization of clinical decision support systems (CDSS), which are information systems designed to assist in clinical decisions by providing alerts, notifications, and links to important information personalized to patients, and the wider use of online evidence-based literature. Lack of time is seen to be one of major reasons that prevent physicians from accessing online literature to answer their clinical questions. In a previous study, 60% of physicians expressed that time was an issue in seeking information while in another study, 40% of clinical questions remained unresolved because of time constraints[6, 7].

Another hindrance that may be intrinsic to the medical profession is confidence in their own clinical knowledge. Physicians who do not perceive the need to access information when faced with a clinical question, may err in their clinical decision. In some cases, a physician may be unaware that there is a gap in their knowledge, thus making no attempt in remedying it[8]. Moreover, previous research demonstrated how some physicians did not even attempt to resolve clinical questions that they acknowledged might have been important in the management of their patients[9-11]. Some researchers proposed that the sociology of being a medical professional, which holds physicians that have expert knowledge and clinical competence in high regard, might explain this behavior[12, 13]. The act and perception of needing to seek knowledge may reflect negatively on a physician's competence and professionalism[14, 15].

In examining the process of how physicians make clinical decisions, an understanding of the cognitive processes of physicians must be considered. Clinical reasoning, which is a necessary cognitive process used to evaluate and manage a patient's medical problem[16], is a major process that defines clinical competence. This competency allows physicians to arrive at their diagnoses and treatment plans[17].

In our understanding of cognitive processes that complicate how physicians arrive at their decisions, we can see the role of confidence in clinical reasoning and information seeking behavior. Physicians who believe that their accumulated clinical knowledge is all they need to reach a correct decision will not be motivated to access external resources and may possibly be inflexible to change a planned management course when information in the EBM literature that may be contrary to their belief is presented[18]. Friedman, *et al.,* who first attempted to examine the relationship between confidence and clinical diagnosis accuracy, proposed four states of concordance or discordance that depend on the alignment of confidence and correctness[18, 19].

In states of concordance, physicians who are confident about their decision are indeed proven correct in their patient management. Conversely, those who are diffident, or are not confident, and are incorrect are also in a state of concordance. Physicians who fall in either of these two states of concordance exhibit appropriate confidence and their beliefs align with reality. The ideal situation would be physicians who are appropriately confident, while those who are appropriately diffident are likely to be receptive to accessing external sources of information. In contrast, states of discordance can be understood as underconfidence and overconfidence. Physicians who are not confident but are correct in their clinical decisions are deemed underconfident. Physicians in this state are more likely to seek information to confirm their decisions, however, it is still possible that doing so may steer them away from their originally correct answer[20]. The state of discordance that is of greatest concern is overconfidence. Physicians in this category are confident in their clinical decisions but in reality are incorrect and are therefore prone to committing medical errors. These physicians are less likely to pursue additional information that could correct their flawed decision.

Motivated by the complex interactions of confidence and decision-making in clinical reasoning, we aimed to determine whether there was a significant relationship between physicians' confidence in their accumulated knowledge in answering clinical cases and the accuracy of these decisions. This study attempted to address the following questions:

1. Is there a relationship between residency year level and clinical decision accuracy?
2. Is there a relationship between confidence and clinical decision accuracy?
3. Does the relationship between confidence and clinical decision accuracy depend per specialty or residency year levels?
4. Does accessing online literature affect clinical decision accuracy?
5. Does the effect of accessing online literature in clinical decision accuracy depend on specialty and residency year level?

Methods

Previous study

With permission from the authors, we reexamined the data collected by Marcelo *et al*. in their study where they compared the effects of using full-text articles against journal abstracts alone in clinical decision accuracy[3]. In that study, an attending physician from four different specialty departments (Family Medicine, Internal Medicine, Emergency Medicine, and Surgery) each prepared five clinical scenarios, specific to their specialty, and with varying complexities. The clinical cases were based on a PubMed search of recent journal articles that contained relevant clinical scenarios with their appropriate diagnostic and treatment recommendations. Resident physicians from each department answered five written clinical cases prepared by their respective attending physicians without access to online resources. After answering the case simulations, each resident was asked to indicate the clinical cases they thought could be accurately answered by accumulated knowledge alone and if they considered that a literature search was needed to arrive at the correct answer. After answering the written cases, each resident answered an online version of the same set of clinical cases, but was given the option to access relevant information either through journal abstracts or full-text articles. The attending physicians who prepared the cases evaluated the accuracy of each resident's answers in both the written (pre-intervention) and online (post-intervention) versions of the clinical cases.

Study design

In this study, we looked at the data on the resident physicians' perceptions on their need for information and their accuracy in answering clinical cases. In our analysis, the participants were additionally stratified based on specialty and year level. We examined the relationship between the residents' confidence and clinical decision accuracy. The data reviewed consisted of 322 cases. Excluded from this review were items where the resident did not indicate their initial perception (n=63).

Responses wherein the resident indicated that their accumulated knowledge was adequate to make a correct clinical decision were categorized to be confident. Responses where the residents expressed the need for accessing online PubMed sources were considered to be diffident. The residents' judgments of their confidence were completed without feedback on whether they were correct or incorrect. Clinical decision accuracy of each case was coded as correct or incorrect.

Data Analysis

In this study, each case paired a resident's subjective assessment of their confidence based on their need for an online literature search with an objective evaluation of their clinical decision accuracy based on correctness on the clinical cases. Chi-square analysis was done to determine if there is a relationship between confidence and clinical decision accuracy across all cases, and stratified based on specialty and residency year level. Cramer's V (V), Phi (φ) and Kendall's Tau-c (τ_c) values were used as symmetric measures to examine the strength of the association when the chi-square values were found to be statistically significant. McNemar's test was done to determine marginal homogeneity in matched pairs that examines the effect of online literature access by comparing clinical decision accuracy at pre- and post-intervention stages. Statistical analyses were performed using IBM SPSS Statistics Software Version 22 software.

Results

Irrespective of physician confidence, we found a small but significant relationship between residency year level and clinical decision accuracy (χ^2=8.077, df=3, p<0.05, τ_c=0.111). First year residents had more incorrect answers (63%) than their more experienced colleagues (45%, 53%, and 50% of 2nd, 3rd, and 4th year residents, respectively). In 228 of 322 cases (71%), residents expressed the need for a literature search to arrive at the correct clinical decision.

We found a small but statistically significant relationship between confidence and clinical decision accuracy in the pre-intervention scores across all cases (χ^2=8.697, df=1, p<0.01, φ=0.164,). Resident physicians were more incorrect (55%) than correct (45%), and more diffident (71%) than confident (29%) regardless of confidence. In total, 60% of the cases demonstrated appropriate confidence or diffidence where the residents' perceived need for information access was aligned with the accuracy of their answers. Calculating the risk ratios of physician confidence and clinical decision accuracy, a diffident physician was 1.42 times more likely to be incorrect than a confident physician. Resident physicians were more often underconfident (28%) than overconfident (12%). Residents were also more often appropriately diffident (43%) than they were appropriately confident (17%). (Table 1) shows a summary of findings.

Table 1. Contingency table on the Alignment of Confidence and Clinical Decision Accuracy

Physician Confidence	**Clinical Decision**		**Total**
	Correct	**Incorrect**	
Confident	17% Appropriately Confident	12% Overconfident	29% Confident
Diffident	28% Underconfident	43% Appropriately Diffident	71% Diffident
Total	45% Correct	55% Incorrect	100%

A separate analysis stratifying cases in their respective specialties found no statistically significant relationship between confidence and clinical decision accuracy.

When stratified based on residency year level, physician confidence had a small effect on clinical decision accuracy among first years (χ^2=4.97, df=1, p<0.05, *V*=0.199) and a medium effect among fourth years (χ^2=4.196, df=1, P<0.05, *V*=0.418). We could see a trend of increasing confidence as resident physicians progress in year levels. First year residents were the least confident (23%) compared to fourth year residents who were confident (46%) on the adequacy of their accumulated knowledge in answering the clinical cases.

Fourth year residents were more appropriately confident (33%) than first year residents (13%). First year residents were more appropriately diffident (52%) than their more senior residents (32%, 40%, and 37% for 2nd, 3rd, and 4th year residents, respectively). Underconfidence decreases when residents reach their 4th year (25, 38, 28, and 17% for 1st, 2nd, 3rd, and 4th year residents respectively) while overconfidence (10,12, 15, and 13% of 1st, 2nd, 3rd, and 4th year residents, respectively) remained consistent.

Association between online literature access and clinical decision accuracy

McNemar's test demonstrated a significant effect of online literature access in clinical decision accuracy (p<0.001) across all cases. Clinical decision accuracy increased from 45% in the pre-test to 72% in the post-test. When clustered by specialty, the effect is statistically significant at p<0.001 except in the Emergency Medicine specialty (p=0.108). Separately for each residency year level, literature access is seen to have a statistically significant effect on clinical decision accuracy except among forth year residents (p=0.180).

Discussion

Overall, we found a small but statistically significant relationship between residency year level and clinical decision accuracy. First year residents had more incorrect clinical decisions than their seniors. This may imply that CDSS might be beneficial when introduced earlier in medical training and education .This is consistent with Friedman's 2001 and 2004 papers that discussed how medical students had more incorrect diagnosis than residents and attending physicians.

In this study, a small but significant relationship between physicians' confidence and their accuracy in clinical decisions was found. Residents were more incorrect (55%) than correct (45%). This highlights the problem of how physicians underestimate their own error rates[25]. When made more aware of these errors, physicians may default to practicing defensive medicine, wherein their lack of confidence leads to unnecessary tests and studies, which are additional burdens to patients[21, 22]. Furthermore, as there was a larger number of instances where residents were not confident, which makes them 1.42 times more likely to be incorrect than they were if they were confident, strategies that increase their clinical competency and in effect, increase their confidence is needed.

Resident physicians were generally more concordant (60%), a setting where their confidence is aligned with correctness, than discordant (40%). In clinical practice, a concordance of confidence and clinical accuracy or correctness is favored more than in cases where there is misalignment. Within concordant cases, residents were also more often appropriately diffident (72%) than confident (28%). This demonstrates that there is a greater likelihood to be incorrect when lacking confidence compared to a marginal chance of being correct when feeling confident. Within cases of discordance, residents were more often underconfident (70%) than overconfident (30%). This finding is similar to the previous study's results that also demonstrated a tendency for clinicians towards underconfidence[32]. This has optimistic implications in the use of CDSS as these physicians are likely to confirm their decisions using external resources.

Additional findings demonstrate that the relationship of confidence and decision accuracy does not depend on specialty. Specialties were equally prone to errors, irrespective of confidence. When clustered by residency year level, a significant relationship was seen among first and fourth year residents, with the latter group having a stronger effect. First year residents were less confident than fourth years. This may be due to a perceived lack of clinical experience, or because they are overmatched by the difficulty of managing patients they see. This is further demonstrated by the fact that first years are more appropriately diffident than fourth years. Fourth year residents on the other hand were more appropriately confident than first year residents. Fourth year residents were also less underconfident compared to the younger residency years. Senior residents may perceive that they have higher clinical competency, and that their clinical experience is correctly matched to the cases compared to their juniors. This evidence of clinical experience bridging the gap between their confidence and accuracy of clinical decisions is similar to previous findings that suggest how higher levels of experience leads to an increased awareness of one's capabilities[32], which then improves the alignment of confidence and accuracy. Overconfidence remains consistent among year levels, which exhibits the role of CDSS in all levels of clinical experience.

Consistent with the findings from the previous study where data in this study was derived from, access to online literature search significantly affects clinical decision accuracy (from 45% to 72% accuracy). When stratified based on specialty, this effect was also significant, except among Emergency Medicine residents. In terms of residency year level, the effect was significant except among 4th year residents. These findings stress how providing access to literature search through CDSS affords statistically significant improvements in the accuracy of making evidence-based clinical decisions in a physician's everyday clinical practice[20].

Limitations

The same limitations from the previous study also apply. The sample size limits generalizability, while the use of clinical cases can only approximate actual clinical encounters. The limited number of cases answered per resident may have also reduced the possible variations in the study. These limitations may have contributed to the small effect sizes observed in the data analysis. In future studies, a larger sample size, pool of cases, and use of quantifiable measures for confidence may help address these limitations.

Conclusion

In this study, we discovered how physicians' confidence based on perceptions for needing access to online literature, plays a vital role in clinical cognition and decision-making. These results demonstrated how misalignments in confidence and clinical decisions due to cognitive processes may affect the accuracy of health care delivery to patients. We also showed further that online literature access improves clinical decision-making. The results indicate that clinical information should probably be 'pushed' to physicians who are overconfident and unlikely to seek information. Furthermore, easy and convenient access to information through different strategies such as practice guidelines, smartphones and mHealth at the point of care will likely benefit underconfident and diffident physicians. Previous studies of have shown the importance of convenient access to evidence where it's needed. These findings have diverse implications in design and implementation strategies of CDSS to support evidence-based practice.

Abstract

Between 2008 and 2010, our academic medical center transitioned to electronic provider documentation using a commercial electronic health record system. For attending physicians, one of the most frustrating aspects of this experience was the system's failure to support their existing electronic billing workflow. Because of poor system integration, it was difficult to verify the supporting documentation for each bill and impractical to track whether billable notes had corresponding charges. We developed and deployed in 2011 an integrated billing application called "iCharge" that streamlines clinicians' documentation and billing workflow, and simultaneously populates the inpatient problem list using billing diagnosis codes. Each month, over 550 physicians use iCharge to submit approximately 23,000 professional service charges for over 4,200 patients. On average, about 2.5 new problems are added to each patient's problem list. This paper describes the challenges and benefits of workflow integration across disparate applications and presents an example of innovative software development within a commercial EHR framework.

Introduction

In the United States, medical billing for a hospital encounter typically includes a bill for facility fees, and separate bills for professional services rendered by physicians. Facility fees cover costs for the room, nursing services, time spent in an operating room, supplies and medications, physical and respiratory therapy, and so on. Professional fees are submitted by physicians for the services they provide during the hospital stay. These services include performing evaluation and management tasks (such as conducting physical exams, diagnosing diseases, and formulating treatment plans) as well as performing surgical and other procedures.

Historically, physician bills were submitted using a standardized paper form called the "Universal Billing Form," which required codes for patient diagnoses and services performed. The modern electronic process requires the same coding requirement for diagnoses and procedures. The International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM) terminology is used to represent diagnoses; it is scheduled to be replaced by the ICD-10 code set in October 2014. Physician services and procedures are typically coded using the Current Procedural Terminology (CPT), a proprietary coding scheme maintained by the American Medical Association.

American Medical Association, the "Physicians' Current Procedural Terminology, Fourth Edition" (CPT-4) is a listing of descriptive terms and identifying codes for reporting medical, surgical, and diagnostic services performed by physicians. This five digit numeric coding methodology is not only utilized for billing purposes, but provides a uniform language applicable to patient care education, research, and utilization comparisons. The "International Classification of Diseases, 9th Revision" (ICD-9), is a numeric coding system describing diseases, symptoms, conditions, complications, external causes, as well as drugs and chemicals.

Between 2008 and 2010, our academic medical center transitioned to electronic provider documentation using a commercial electronic health record system (Allscripts Sunrise, Allscripts Corp., Chicago, IL). By December 2010, approximately 30,000 physician notes were electronically authored each month. For attending physicians, one of the most frustrating aspects of the transition to documenting in the EHR was the system's failure to support their existing electronic billing workflow. Physicians were required to author admission, follow-up, consultation, and discharge notes in the inpatient EHR, and log in to a separate system (the EHR used in their ambulatory practices) to submit charges. Users had to manually manage separate patient lists in each application. Furthermore, because of poor system

integration, it was difficult to verify the supporting documentation for each bill and impractical for administrators to track whether billable notes had corresponding charges.

We developed and deployed in 2011 an integrated billing application called "iCharge" with the goal of streamlining clinicians' documentation and billing workflow across two different commercial EHRs, and simultaneously populating the inpatient problem list using billing diagnosis codes in a timely fashion at the point of care. This paper describes the design and implementation of the iCharge application, focusing on the challenges and benefits of workflow integration across disparate applications.

Methods

iCharge Architecture

The integrated charge application was designed to be accessed from the inpatient EHR but provided the same look-and-feel as the physicians' existing billing system, which was a module within a separate ambulatory EHR system (Allscripts Enterprise EHR, Allscripts Corp., Chicago, IL). (In 2010, the inpatient EHR vendor, Eclipsys Corp., was acquired by Allscripts Corp., but the inpatient and outpatient EHR products remain separate products, with different databases and front-end interfaces.) iCharge was developed using Visual C# (Microsoft Corp., Redmond, WA), and communicated with the inpatient EHR using the vendor's included application programming interface (API) known as ObjectsPlus. The API allowed iCharge to leverage core EHR components such as role-based access and security auditing. Charges were submitted through web services (referred to as "Unity") provided by the ambulatory EHR infrastructure and would appear as normal charges in that system, with the substantial improvement of displaying the information (note name and author time) for the documentation that supported the charge. Figures 1–2 show illustrative screenshots of the application for a fake patient.

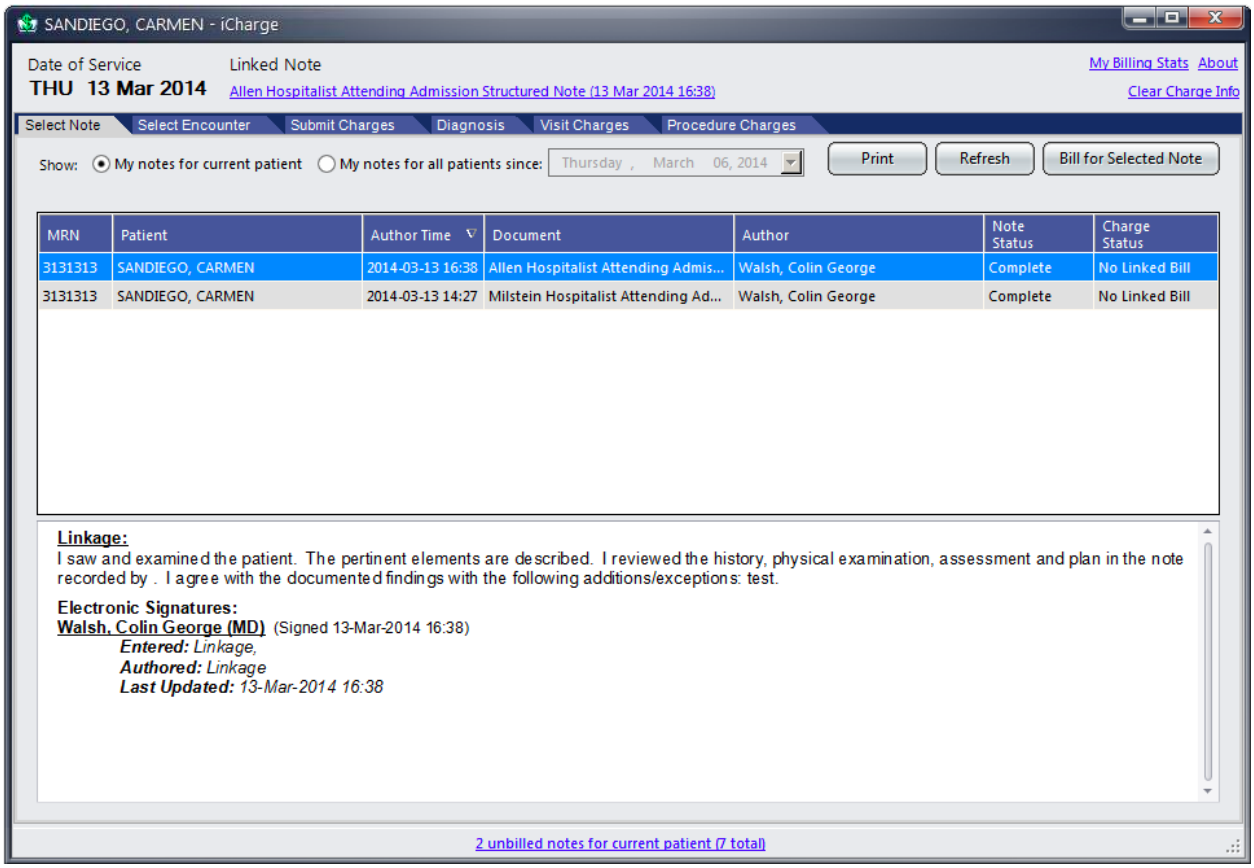

Figure 1. Screenshot of iCharge illustrating the "Note History" feature, where clinicians can review their billing history for each note authored in the inpatient electronic health record.

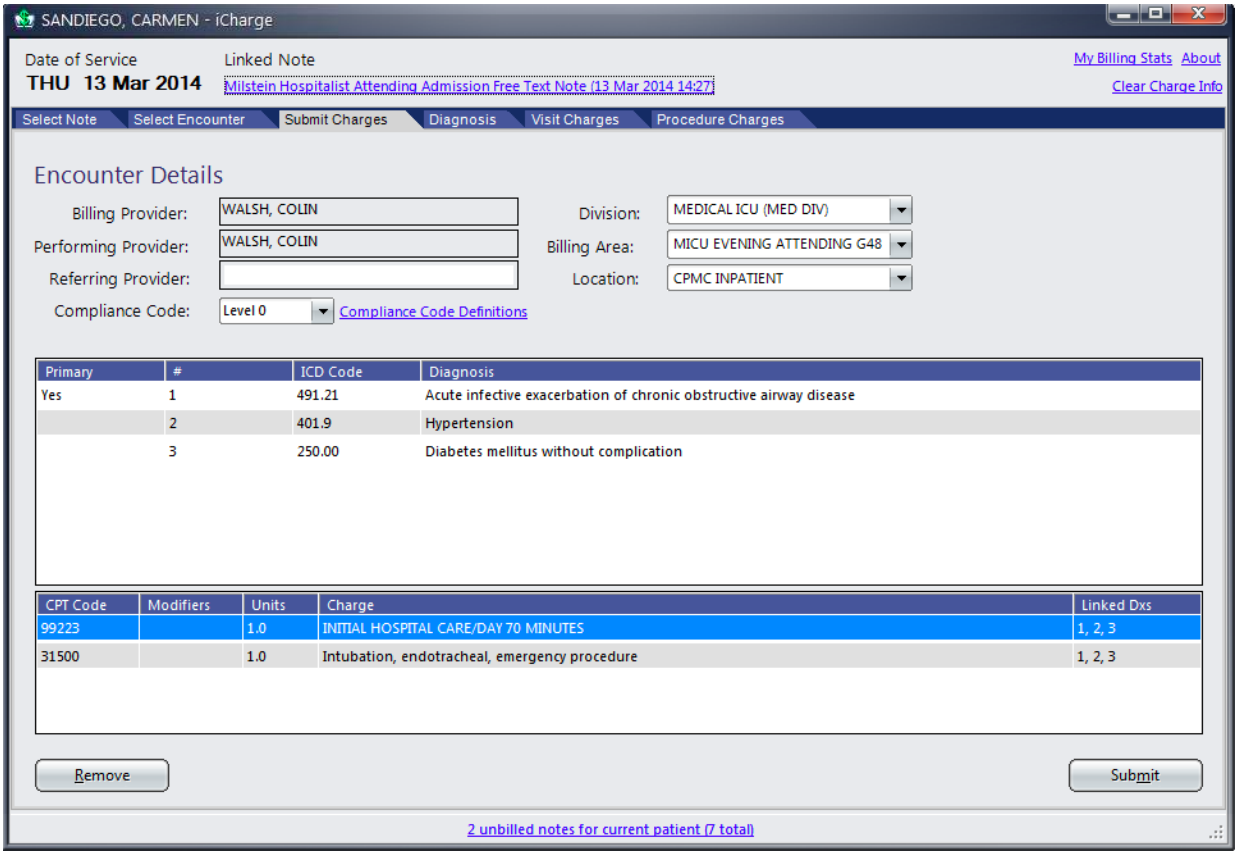

Figure 2. Screenshot of iCharge illustrating the "Note History" feature, where clinicians could review their billing history for each note authored in the inpatient electronic health record.

Workflow & Cognitive Support Characteristics

For health information technology to be most effective, it should provide users with the cognitive support necessary to complete the tasks it is designed to accomplish. (1) Informatics experts have observed that clinical information systems often lack adequate usability testing and demonstrate an apparent lack of clinical input in the design process. (2) The iCharge application was designed to be closely integrated with practitioners' documentation workflow. After a note was electronically signed by an attending physician in the EHR, a pop-up reminder (Figure 3) prompted him or her to generate a bill. Through this workflow, iCharge automatically associated the bill with its supporting documentation. Alternately, physicians could use a "Note History" function in iCharge to review and edit the billing status of all of the notes they authored in a specified time period. Using this function, clinicians could keep track of billable notes they had authored, but for which they had not yet submitted a bill. From within iCharge, clinicians could also view basic statistics about their billing practices compared to other iCharge users (e.g., number of bills submitted, average number of diagnosis codes included in each bill).

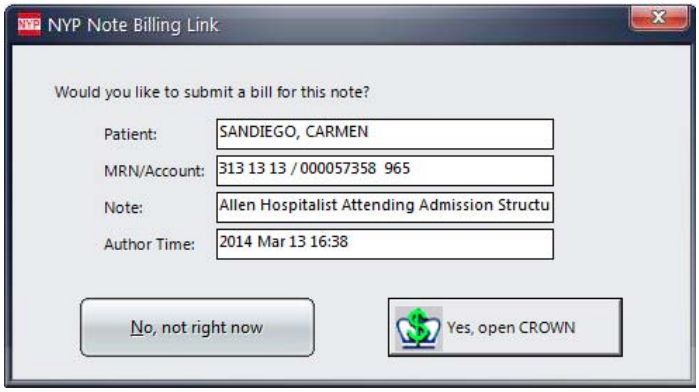

Figure 3. Reminder that appears upon signing an electronic note, prompting clinicians to submit a bill.

The iCharge application was designed to enable fast and efficient searching of diagnoses, which is an important feature as institutions throughout the U.S. prepare for the transition from ICD-9 to ICD-10 billing diagnosis codes. The diagnosis selection module allowed users to select from a patient's previous diagnoses and from lists of 'personal' and 'group' favorites (e.g., the 'Pediatric

Infectious Disease' group contained 16 frequently used billing diagnosis codes). A full catalog search provided suggestions for codes based on partial matches of numerical codes or text descriptions of ICD-9, ICD-10, or IMO (Intelligent Medical Objects) concepts. IMO (Northbrook, IL) provides an extensive terminology of physician-friendly terms that are mapped to ICD codes; the terminology has been incorporated into several commercial EHR systems. The iCharge diagnosis selection module was configured to prompt the clinician to specify a more granular code if an ICD-9 code was selected which mapped to more than one ICD-10 code.

In November 2013, iCharge was modified so that every billing diagnosis was automatically saved to the inpatient EHR's problem list. Prior to that time, physicians could manually save billing diagnoses to the problem list with an additional mouse click. The auto-save function was added as part of an institutional effort to improve the comprehensiveness and accuracy of the problem list.

Measurements

We retrospectively reviewed the system logs generated by iCharge and the inpatient EHR to evaluate system use. With data from the institution's practice management system, we calculated the average "turnaround time" for charges—the number of days between the date of service on a bill and the date the bill arrived in the practice management system.

For a three-month period, we measured monthly use of iCharge in terms of number of users, number of bills submitted, and patients with bills submitted. We queried from the inpatient EHR during the same time period the number of attending physicians authoring notes, number of notes authored, and number of patients with notes authored. We also measured from iCharge the mean number of billing diagnoses included per charge, as well as the average number of new diagnoses added to the inpatient Problem List per patient. Finally, we assessed the delay in days between the time a note was authored in the inpatient EHR and a corresponding charge was submitted via iCharge.

Results

The iCharge application was first made available to beta users in January 2011 and deployed to all attending physicians during the subsequent months. Its use was optional, but over time, the majority of billing clinicians in the institution began using the application (Figure 4). No formal training was conducted to instruct clinicians on the use of the application; however, one of the authors (PDS) created a short instruction guide, referred to locally as a "job aid," and other training materials that were made available to users of the application. By February, 2014, the majority of inpatient services were using iCharge, though some continued to bill using other means. A typical bill submission in iCharge required 30–60 seconds to complete.

Adoption

Use of iCharge was measured by reviewing audit log data from November 1, 2013 to February 1, 2014. Table 1 shows the number of users, charges submitted, average diagnoses per charge, average number of new diagnoses added for each patient.

Table 1. Use of an integrated billing application during three months at Columbia University Medical Center.

Measure	Nov 2013	Dec 2013	Jan 2014
Attending physician EHR note authors	775	793	805
Patients with notes authored by attending physicians	5,040	4,981	5,214
Total attending physician notes authored	32,424	31,413	33,901
iCharge users	427	430	436
Patients with charges submitted via iCharge	4,178	4,050	4,369
Total charges submitted via iCharge	23,225	23,364	24,616
Average number of billing diagnoses per charge in iCharge	2.70	2.81	2.80
Average number of new diagnoses added to inpatient problem list per patient via iCharge	2.54	2.68	2.45

Timeliness of Billing

Figure 5 shows a histogram of charges submitted in iCharge based on day of note authoring. The vast majority of charges were submitted on the same day that the supporting documentation (i.e., the attending physician's follow-up note) was authored. Approximately 9 months after iCharge was implemented, **t**he average turnaround time for charges had decreased from 5.67 days to 4.42 days (95% CI=0.09).

Problem List Impact

For the three months prior to enabling the auto-save of billing diagnoses to the inpatient EHR problem list, the number of manual save events (where physicians clicked to add their billing diagnoses to the problem list) averaged 37.1/day. After the auto-save feature was implemented, billing diagnoses were added to the problem list every time a charge was submitted; on average, 757 times/day. Duplicate diagnoses were not added. The average number of new diagnoses added to the problem list for each patient after the auto-save feature was added was about 2.5/patient (Table 1).

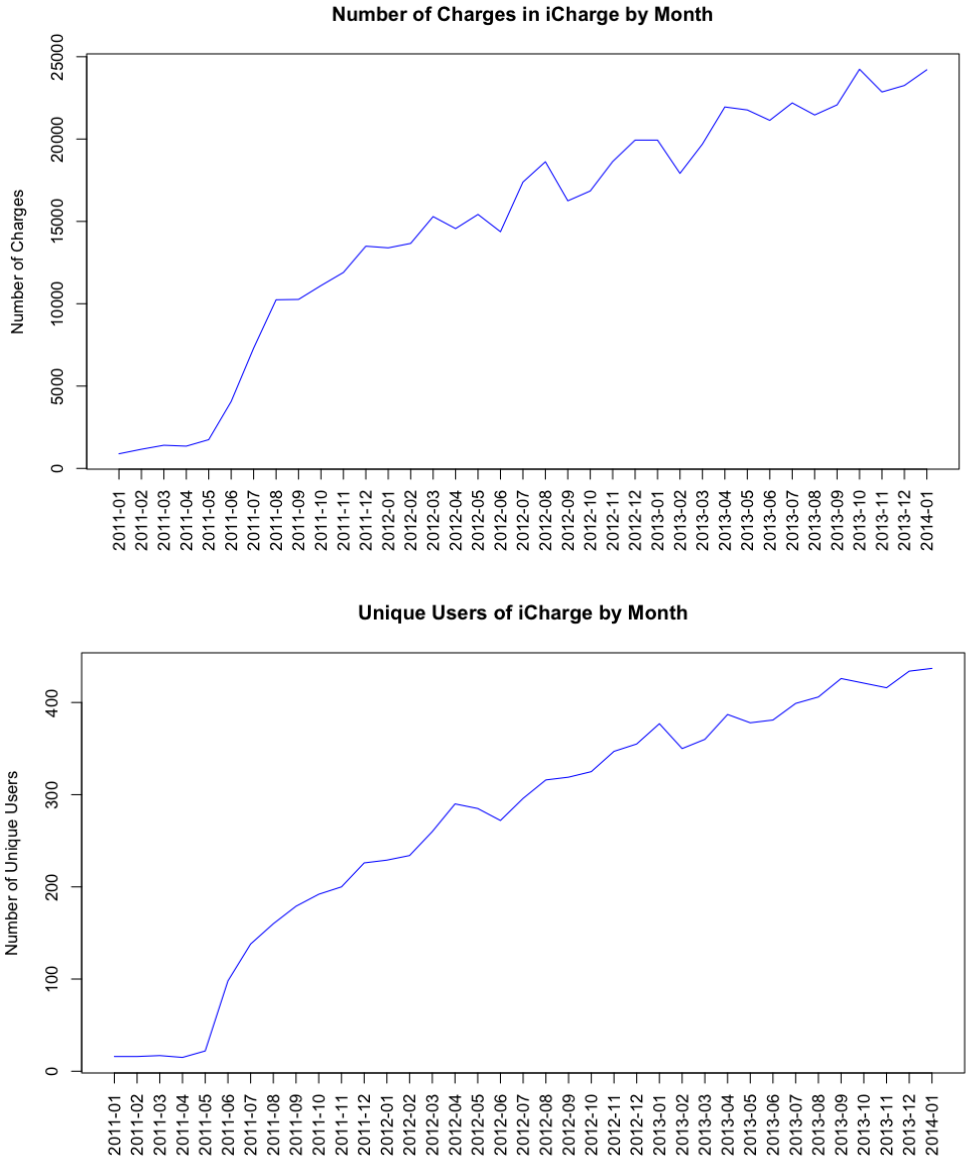

Figure 4. Monthly count of submitted bills and unique users of iCharge.

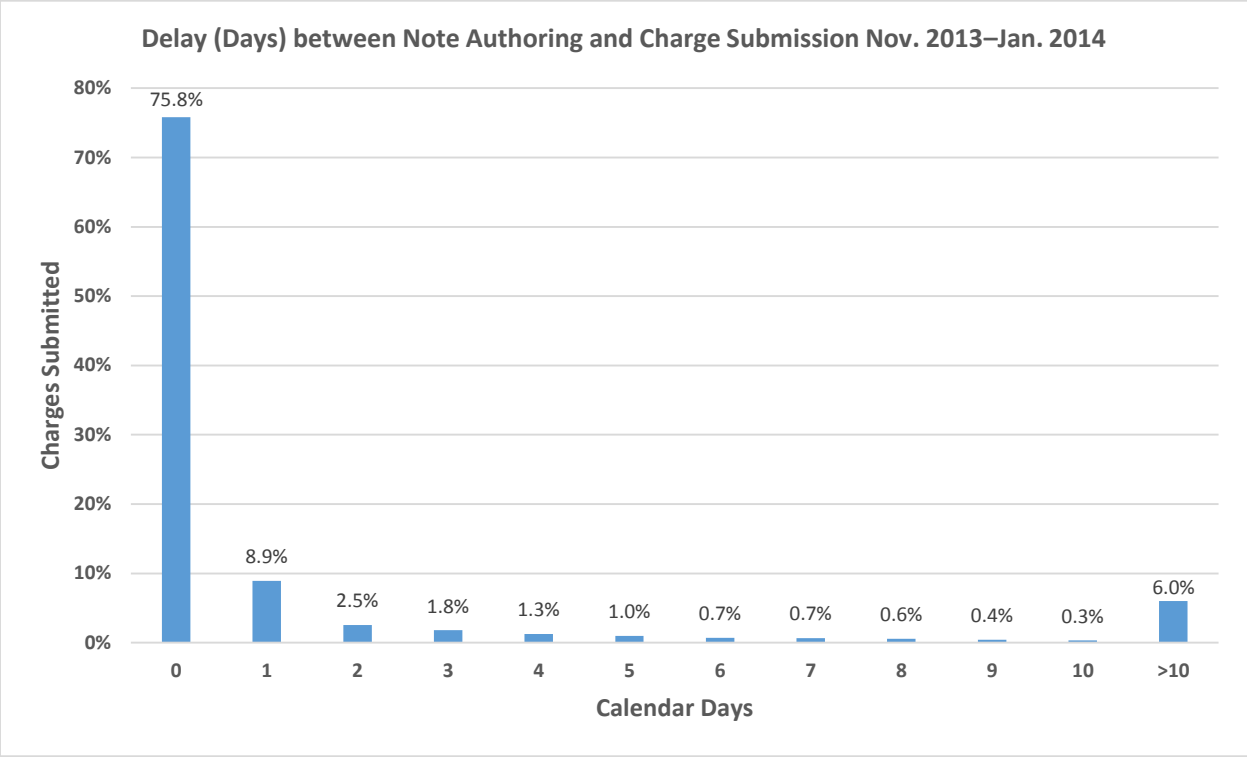

Figure 5. Frequency of charges submitted in iCharge based on day of note authoring.

Discussion

Importance of Workflow Integration

Even the most promising new informatics interventions may have little impact if they do not fit into clinical workflows (3, 4). The iCharge application was voluntarily adopted by over 400 physicians at our medical center primarily because it was closely integrated into their existing documentation workflow. With iCharge, physicians were no longer required to log into multiple systems, maintain multiple patient lists, or rely on their own memory to determine which notes had corresponding bills.

In spite of the fact that EHRs are frequently viewed as a means to promote "improved billing and collection," questions remain regarding the return on investment of these systems. (5-9). Unlike iCharge, the billing functionality in many commercial EHRs is not closely aligned with note-writing, even though there is strong evidence that tying note-writing to inpatient charge capture improves key financial indicators (10). Not only did iCharge offer clinicians the tools to better manage their documentation/billing workflow, it facilitated the creation of administrative reports that uncovered previously undetected trends in charge capture among providers, groups, and departments across our organization.

Benefits and Challenges with Implementing Custom Software in Commercial EHR Environment

Healthcare delivery organizations that use a single EHR system in across all care settings may have less need for solutions like iCharge; however, there are many valid reasons for institutions to develop custom software applications. For example, few institutions are likely to be perfectly happy with any commercial EHR system "out of the box." Most EHR vendors include some capability to develop custom software to address local needs. Moreover, because of the breadth and complexity of healthcare information technology, few organizations can rely on a single software vendor to meet all of their needs. Thus, interfaces and system integration will always be necessary. While many informatics discussions focus on interoperability at the data or system level (11), we believe that "workflow

integration" will become increasingly important. The iCharge project is one successful example of integrating workflows across disparate information systems.

Custom software development is not without its challenges. Healthcare delivery organizations are seldom staffed adequately to engage in large-scale software development efforts, particularly when it comes to testing, documentation, and maintenance. Information technology decision-makers should be judicious and pragmatic in deciding when to "build" and when to "buy" (12). Our organization has experienced a degree of success with custom application development to fill gaps that remained after installing a commercial EHR. We have benefitted from the vendor's open architecture, which enables us to create workflow-sensitive cognitive support tools, including for patient safety activities and regulatory/operational requirements (13).

Improving Problem List Documentation

One of the side benefits of using iCharge was that structured problems, in the form of diagnosis codes, were automatically added to hospital patients' problem lists. On average, patients whose physicians billed using iCharge gained an additional 2.5 problems. The need for a standardized approach to coding a problem list has been emphasized in the literature, but expecting providers to spend additional time coding problems in addition to their usual clinical work places demands on overall productivity (14-16). Prior work has outlined a number of useful approaches to increasing the number of problems on the problem list, including natural language processing, semantic annotation, predictive algorithms (17-22). In contrast to these approaches, the "auto-save" approach in iCharge may be less expensive both financially (i.e., in terms of human effort) and computationally.

Over the years, informatics experts have debated whether ICD-9 codes are sufficiently granular to be beneficial as a coding format for a patient problem list (23-27). We recognize that billing codes—in any format—may not perfectly represent the nuances of clinical care (28, 29), but we also believe that even a basic coded problem list has important clinical implications to ensure alerts are triggering on appropriate patients and that medications are being prescribed to those cohorts who need them (30, 31). The U.S. Meaningful Use financial incentive program requires hospitals to maintain a coded, structured problem list, and the program allows ICD-9 codes as a suitable format for encoding problems. Though it will likely involve a painful transition for many organizations, ICD-10 will provide clinicians with an order of magnitude more codes--and considerable more granularity—than ICD-9 codes afford. Thus, we anticipate that our method for automatically converting provider billing codes to problems on the problem list will continue to yield benefits for our organization, and may also generalize to others.

Conclusion

The integrated billing application that we created within our commercial EHR environment streamlines clinicians' documentation and billing workflow and simultaneously populates the inpatient problem list using billing diagnosis codes. The application has been widely adopted at our institution, demonstrating the importance of health information technology that matches the needs of busy clinicians. The success of the application provides evidence that innovative solutions can be implemented within the framework of a commercial EHR system.

Mining Consumer Health Vocabulary from Community-Generated Text

Abstract

Community-generated text corpora can be a valuable resource to extract consumer health vocabulary (CHV) and link them to professional terminologies and alternative variants. In this research, we propose a pattern-based text-mining approach to identify pairs of CHV and professional terms from Wikipedia, a large text corpus created and maintained by the community. A novel measure, leveraging the ratio of frequency of occurrence, was used to differentiate consumer terms from professional terms. We empirically evaluated the applicability of this approach using a large data sample consisting of MedLine abstracts and all posts from an online health forum, MedHelp. The results show that the proposed approach is able to identify synonymous pairs and label the terms as either consumer or professional term with high accuracy. We conclude that the proposed approach provides great potential to produce a high quality CHV to improve the performance of computational applications in processing consumer-generated health text.

Introduction

Over the past decade, there has been a significant increase in the consumption of online health information by the general public. According to a 2013 Pew Research Center survey, 72% of U.S. adult Internet users have looked for health information online; and, among them, 59% have sought information about specific medical conditions.[1] However, it has been long recognized that laypersons and healthcare professionals think about and express health-related concepts very differently,[2] for example, "dry mouth" vs. "xerostomia" and "flu" vs. "influenza". This mismatch in the terminology and style of writing could diminish laypersons' ability to effectively find and comprehend online health information written by professionals or experienced patients.

On the other hand, community-generated data on the Internet have also been increasingly used as a source of information to support professional needs such as public health surveillance and scientific discovery.[3] For example, scientists at Google analyzed search queries submitted by millions of users worldwide to detect the outbreak and spread of influenza-like epidemics,[4] and pharmaceutical companies are routinely monitoring online social conversations for post-market drug research.[5-8] In order to properly extract relevant concepts from community-generated text corpora, a high-quality consumer health vocabulary (CHV) is often needed to specify how a particular health-related concept may be expressed differently in laypersons' terms vs. in a professional language. The accuracy and comprehensiveness of CHVs can be crucial to the performance of computational tools that make use of community-generated health text such as health-related tweets and patient posts in online health forums.

Many resources are available for describing and classifying medical concepts used in the professional settings, such as the Systemized Nomenclature of Medicine Clinical Trials® (SNOMED-CT®), the Logical Observation Identifiers Names and Codes (LOINC), and other biomedical vocabularies and ontologies included in the Unified Medical Library System (UMLS) Metathesaurus. However, vocabularies providing consumer-oriented health terms are relatively less mature. This fact diminishes the performance of named-entity recognition tools for processing community-generated text[9] as well as the potential for building applications that could "translate" professional language into layperson terms to improve readability and facilitate comprehension (e.g. to support the OpenNotes project that shares clinician notes with patients[10]).

Community-generated text corpora could serve as a valuable resource to extract laypersons' expressions of medical concepts (i.e., consumer terms) and their corresponding professional expressions. Wikipedia is one such rich resource that is frequently updated and popularly accessed by the general public. It is estimated that the medical entries on Wikipedia are accessed more than 180 million times a month, and about 1,000–2,000 edits are being made to them each day.[11] Further, it is also estimated that about half of the Wikipedia users who edit the medical entries are healthcare professionals; the remainder are patients, families, and the general public.[11] Thus, it is likely that the

Wikipedia medical entries contain both the professional terminology and laypersons' terms, linked by some semantic relationships (e.g., "influenza, commonly known as the flu"), which provides the basis for this research.

In this paper, we propose a pattern-based text-mining approach to identify pairs of professional terms and their consumer variants from Wikipedia, in addition to their alternative spellings and synonyms. We also describe a computational approach to validate the extractions and to label the terms in a pair as either "professional" or "consumer". This approach is based on the frequencies of a term appearing in MedLine,[12] which indexes scientific papers produced by the professional community, and in MedHelp,[13] a popular online health forum where the content is mainly generated by laypersons. A subsequent manual review of the extracted and labeled pairs of entities was conducted to validate the results generated by the computational approach. The results are very promising.

Background

The use of Wikipedia by laypersons and medical professionals has become a subject of active research in recent years. Several studies have shown that Wikipedia is one of the leading online destinations for health information seekers.[14-16] For example, recent surveys reported that 60% of European doctors use Wikipedia for professional purposes,[14] and nearly 50% of U.S. physicians who go online for information on specific medical conditions use Wikipedia.[15,16] These studies corroborate the findings published in peer-reviewed articles on the use of Wikipedia as a source of information for scientific and medical professionals,[17-19] as well as medical students.[20-25] Studies have also shown a growing use of online medical resources including Wikipedia by patients, caregivers, and healthcare consumers,[26-29] and that Wikipedia articles often appear in the top results provided by Web search engines.[30]

Identifying all medical entities from free text is an active area of research in natural language processing. Lexico-syntactic pattern-based approaches have been well established for over thirty years and have supported numerous information extraction tasks such as hyponym identification,[31] semantic classification,[32,33] meronym identification,[34] and large scale information extraction over the Web.[35] This paper builds on similar ideas to identify and leverage key textual patterns that are frequently used to present synonymous terms in Wikipedia. Automatic term recognition (ATR) techniques, sometimes called named entity recognition (NER) techniques, have also been proposed to identify valid candidate terms in biomedical text corpora,[36-40] using sequential models[41-43] and term scoring approaches.[44,45] In this study, we investigated if the rich formatting styles used by editors in Wikipedia and other wiki-based corpora give sufficient cues to extract consumer vocabulary terms with high accuracy.

Methods

In this section, we present the process used to identify and extract names of medical entities and their alternate synonym variants from Wikipedia. Figure 1 summarizes the system design, and the following paragraphs describe the process in detail.

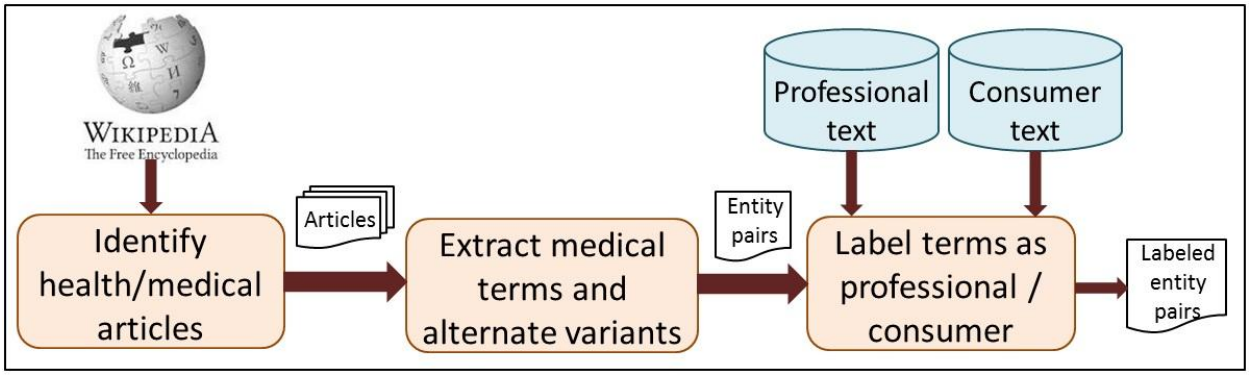

Figure 1. System work flow to extract and label professional and consumer health vocabulary.

Identifying relevant Wikipedia articles

Wikipedia releases periodic snapshots of all the articles published on the website, along with any associated metadata.[46] Each article contains the title, revision information, and the complete text. The text is typically unstructured and the formatting information, such as bold face or italicized fonts, citation information, and hyperlinks to other Wikipedia articles, is added with a marked up schema using special character sequences (such as two consecutive square brackets, three consecutive apostrophes, etc.). For this study, we considered the complete English language Wikipedia, which consists of over four million articles, and nine million additional pages for redirects, stubs, lists, and category pages.

Most Wikipedia articles also contain a list of tags that specify, for each article, a set of relevant categories from Wikipedia's hierarchical topic classification scheme.[47] At the top most level, this scheme consists of twenty five categories. Two of these are *Health* and *Medicine*. These top-level categories are further divided into additional sub-categories. For example, *Clinical medicine* is a sub-category of *Medicine*, and *Medical diagnosis* is a sub-category of *Clinical medicine*. The complete category hierarchy can be obtained by repeatedly traversing the sub-category links.

We collected a list of all sub-categories for *Health* and *Medicine* down to a depth of three, using an external Wikipedia tool called CatScan.[48] CatScan recursively searches an article category to find all articles, sub-categories, images, etc. This resulted in a list of 2,331 candidate categories. Once the relevant categories were identified, all four million Wikipedia articles were programmatically checked to retain only those articles that were tagged with at least one of the candidate categories. This narrowed the number of potential medically relevant articles to about 46,000, which constitutes about 1.2% of all articles in English Wikipedia.

Extracting medical terms and their common alternate names

Wikipedia articles are often written and formatted to serve as an introduction to the topic of the article.[49] Typically, the first sentence is formatted such that the article title appears in bold face as the subject of the definition or introduction. If the title also has alternate forms, such as abbreviations, alternate spellings, or significant alternate titles, these also appear as bold face immediately following or adjacent to the first occurrence of the title. For example, the Wikipedia article on "xerostomia"[50] starts as:

> **Xerostomia** (also termed **dry mouth** or **dry mouth syndrome**) is the medical term for the subjective symptom of dryness in the mouth, …

informing readers that "dry mouth" and "dry mouth syndrome" are alternative names for "xerostomia".

This relatively consistent style lends itself to devising automated text-mining and information extraction techniques. Through an iterative process of reviewing medical articles on Wikipedia, we identified a list of phrases that generally connected a medical concept term to its alternate terminology. Table 1 lists twelve examples of common linking phrases.

Table 1. Common linking phrases.

also called	commonly called	sometimes called	also termed
also known as	commonly known as	sometimes known as	previously known as
also referred to as	commonly referred to as	sometimes referred to as	colloquially known as

In addition to the linking phrases, parentheses also serve as a textual clue to introduce alternate spellings, abbreviations, and synonyms. Multiple alternate terms are mentioned in a comma-separated list, or separated by conjunctions such as "or" and "and". Each alternate form is typeset in bold face or italicized text. Additionally, hyperlinks are used to link phrases to articles about other related concepts.

Wikipedia articles were parsed to identify the title, and the leading text paragraph. All bold face, italicized, and hyperlinked phrases in the lead paragraph were identified as candidates. The common linking patterns were applied to extract pairs of linked candidate entities. For instance, applying this technique to the example above would generate two pairs: ("xerostomia", "dry mouth") and ("xerostomia", "dry mouth syndrome").

Labeling terms as consumer or professional

Although Wikipedia articles mention the alternate variants for a term, they do not specify which terms are likely to be used by consumers and which ones by professionals. Hence, simply extracting these relationships directly from Wikipedia does not provide enough detail to build a CHV, or to map between consumer and professional terms because there is no label assigned to each term.

It can be difficult to categorize terms as belonging to professional or consumer vocabulary. Frequently, health terms used by professionals migrate or evolve into popular vernacular as they become well known.[51] The acceptance or preference of a term can be measured, however, based on how often the term is used by the community. Specifically, if a term is more prominently used in professional text that is generated by and primarily intended for medical professionals, it can be regarded as professional. Conversely, if a term is frequently used by laypersons but not as often by medical professionals, then the term is more likely to be in a consumer-preferred vocabulary.

To quantitatively measure the propensity of a term T to be a consumer-oriented term, we define the following measure:

CHV_propensity (T) = count(T occurs in a consumer text corpus) / (size of the consumer text corpus)

Similarly, we can measure the propensity of a term T to be a professional term, as

PROF_propensity (T) = count(T occurs in a professional text corpus) / (size of the professional text corpus)

We propose that a term is more likely to be a consumer-oriented term if and only if its CHV_propensity is higher than its PROF_propensity. We refer to this intuition as the *propensity argument*.

To label a pair of terms (A, B) as professional or consumer with respect to one another, we can extend the propensity argument to the following. A is said to be the professional term and B is said to be the consumer term, if

$$\frac{\text{PROF\_propensity (A)}}{\text{CHV\_propensity (A)}} > \frac{\text{PROF\_propensity (B)}}{\text{CHV\_propensity (B)}}$$

or alternately,

$$\frac{\text{PROF\_propensity (A)}}{\text{PROF\_propensity (B)}} > \frac{\text{CHV\_propensity (A)}}{\text{CHV\_propensity (B)}}$$

which is the same as saying

$$\frac{\text{count(A occurrences in professional text)}}{\text{count(B occurrences in professional text)}} > \frac{\text{count(A occurrences in consumer text)}}{\text{count(B occurrences in consumer text)}} \quad \text{(Eq. 1)}$$

Conversely, if the condition is not met, then A is said to be the consumer term and B is said to be the professional term. Note that when comparing two terms using Eq. 1, the relative sizes of the corpora do not matter. However, the statistics collected over large corpora are more robust. Even when text corpus sizes are large, some concepts might occur infrequently or not appear at all. Such cases are avoided by smoothing the counts using Laplace smoothing.[52]

We chose online health discussion forums as a representative of consumer language. We crawled all the questions and comments posted by members on community discussion forums on MedHelp.[13] MedHelp is one of the earliest and well-known online forums dedicated to supporting user-driven discussions on health or healthcare related topics. The dataset consists of approximately thirty million messages posted by about a million unique users, and contains approximately 450 million words. This dataset has been a subject of study in other research endeavors.[53] In the following analysis, we refer to this as the **consumer text corpus**.

As a representative of professional text, we chose the abstracts of articles published in scientific journals and included in the 2012 MEDLINE®/PubMed® Baseline distribution.[12] To create a comparable corpus (in terms of word counts) to the consumer text corpus described earlier, we processed two million citations from the Baseline distribution that corresponded to papers published between 2008 and 2012. Titles were excluded from the generated professional text corpus. In the following analysis, we refer to this corpus as the **professional text corpus**.

To evaluate the accuracy of labeling professional and consumer terms in the extracted pairs, a medical expert conducted a manual review. First, the extracted pairs were filtered such that both terms appeared at least five times in both professional and consumer text corpora. A sample of 100 pairs was then randomly selected from this filtered set and manually judged and coded by a medical expert as one of the following classes: (a) valid pairing with correct labeling, (b) valid pairing with incorrect labeling, (c) pairs of equivalent concepts that either have alternative spellings or are synonymous, (d) pairs of related items, but not in a professional-consumer setting, such as an "is-a" relationship, or (e) invalid pairings. The pairs coded as equivalent or related (classes (c) or (d) above) were further coded to check if they were spelling variants, in case of equivalent pairs, or had a hierarchical ("is-a") relationship, if they were initially coded as related. The analysis of the expert judgment is presented in the Results section.

Results

Extracting pairs of medical concepts and their alternate names

Applying these techniques over the filtered set of medical articles from Wikipedia, we obtained 2,721 pairs of concepts and their consumer-preferred alternate names. Table 2 lists the linking patterns used, along with number of concept pairs each pattern generated. We also list a few examples of pairs extracted using that pattern.

Table 2. Patterns used to find pairs of alternate names, along with the count of pairs extracted and a few examples.

Linking pattern	Count	Examples
also known as	1695	(hematocrit, packed cell volume); (hair removal, epilation); (leukopenia, leukocytopenia); (dentures, false teeth)
also called	604	(heat therapy, thermotherapy); (hypersalivation, ptyalism); (nephroptosis, floating kidney); (dark therapy, scototherapy)
commonly known as	157	(nitrous oxide, laughing gas); (calcium oxide, quicklime); (pleurothotonus, Pisa syndrome); (*nepeta cataria*, catnip)
also termed / referred to as	106	(vertebral osteomyelitis, spondylodiskitis); (periapical cyst, radicular cyst); (red blood cells, erythrocyte); (posterior ramus syndrome, Maigne syndrome)
commonly called / referred to as	61	(peripheral vascular disease, peripheral artery disease); (actaea, baneberry); (schizophasia, word salad); (unnecessary health care, overtreatment)
sometimes called / termed	45	(high blood pressure, arterial hypertension); (chalicosis, flint disease); (hemiballismus, ballism); (irritable male syndrome, Del syndrome)
sometimes known as / referred to as	33	(pentazonia, giant pill millipedes); (hypochondria, health phobia); (ocular dominance, eyedness); (sexual addiction, sex addiction)
previously known as / called / referred to as	14	(acute kidney injury, acute renal failure); (erythrovirus, parvovirus B19); (periodic limb movement disorder, nocturnal myoclonus); (ankylosing spondylitis, Bechterew's disease)
colloquially known as / called / referred to as	6	(halitosis, bad breadth); (coal workers pneumoconiosis, black lung disease); (asystole, flatline); (central facial palsy, central seven)
Total pairs	**2721**	

We observe that a majority of extracted pairs come from the pattern "also known as". Further, 90% of the extracted pairs come from the top three patterns. We also observe that for some patterns such as "commonly known as" or "colloquially known as", the consumer-preferred terminology usually occurs as the second part of the extracted pair. However, these patterns contribute only about 8% of the extracted pairs. In pairs extracted using other patterns, the consumer term could appear in either positions.

Labeling the extracted pairs

To evaluate the accuracy of labeling the terms in each extracted pair as "professional" or "consumer" terms, a medical expert reviewed a sample of 100 pairs, as described in the Methods section. Each pair was manually coded by the expert as one of the following classes: (a) valid pairing with correct labeling, (b) valid pairing with incorrect labeling, (c) pairs of equivalent concepts that either have alternative spellings or are synonymous, (d) pairs of related items, but not in a professional-consumer setting, such as an "is-a" relationship, or (e) invalid pairings. Table 3 summarizes the results.

Table 3. Classification of 100 pairs of extractions, with examples. In the examples provided, the professional term as defined by the expert reviewer is shown first and the consumer term is shown second.

Code	Class of instance	Counts	Example pairs
(a.0)	Valid pairing with correct labeling	54	(icterus, jaundice); (pyrosis, heartburn); (oral candidiasis, oral thrush); (somnambulism, sleepwalking); (tinea, ringworm)
(b.0)	Valid pairing with incorrect labeling	4	(chronic renal disease, chronic kidney disease); (ovum, eggs); (brucellosis, Mediterranean fever); (hyperplasia, proliferation)
(c.1)	Alternative spelling variants	8	(leukoplakia, leucoplakia); (fecal incontinence, faecal incontinence); (post-concussion syndrome, postconcussive syndrome)
(c.2)	Synonyms or equivalent	23	(orthostatic hypotension, postural hypotension); (viral load, viral titer); (Lugols iodine, Lugols solution); (mouthwash, mouth rinse); (fecal incontinence, anal incontinence);
(d.1)	Is-a mapping	2	(cannabinoid, endocannabinoid); (radiology, radiation oncology)
(d.2)	Related concepts	9	(hypersensitivity, intolerance); (medical test, diagnostic technique); (medical procedure, technique); (pain management, pain medicine); (keratosis, keratotic); (suffering, aversive); (nerve, innervation); (tracheotomy, tracheostomy); (coccidioidomycosis, cocci)

From Table 3, we first observe that 89% of the pairs are between synonymous or equivalent concepts (Table 3, rows (a.0), (b.0), (c.1), and (c.2)), while the remaining instances were mainly between related items that are not an exact synonym of one another. In the current study, since the focus is on identifying medical terms and their equivalent consumer terms, related concepts (Table 3, rows (d.1) and (d.2)) are less desirable than the valid mappings. None of the 100 extracted pairs were judged invalid or to be between unrelated medical concepts.

Among the 89 pairs identified as valid pairs, 58 pairs (65.2%) were judged to be valid mappings between a professional term and a consumer term. The remaining pairs were either synonyms or equivalent concepts, both of which are valid professional terms. It is instructive to note that even when two terms are profession terms, one is often more widely accepted and used in consumer-generated corpora. For example, the terms "orthostatic hypertension" and "postural hypotension" appeared with similar frequencies in the professional text corpus, but the latter variant was observed 7.5 times more frequently than the former in the consumer text corpus. Hence, our approach labeled "postural hypotension" as the consumer term in the above example pair.

The approach to label terms as consumer or professional was also fairly accurate. For four pairs, the expert labels mismatched those assigned automatically (using the propensity argument, Eq. 1). Comparing against the 54 instances that were judged and labeled the same, this leads to a labeling accuracy of 93.1%. All four instances have been listed as examples in the table (Table 3, row (b.0)).

Identifying new mappings between professional and consumer terms

Finally, we also compared the pairs obtained by the proposed method against the CHV files made available by the open access and collaborative (OAC) CHV initiative.[54] Our approach generated many new pairs that were not included in the existing databases of consumer health vocabulary. Table 4 lists a few such examples of pairs extracted from Wikipedia articles.

Table 4. Examples of new pairs of professional and consumer terms that are not included in available CHV datasets.

Professional term	Equivalent consumer term
ambulatory surgery	outpatient surgery
arterial hypertension	high blood pressure
asphyxiation	lack of oxygen
Biofilms	Plaque
conjunctivitis	pink eye
dermatophytosis	Ringworm
Ethanol	drinking alcohol*
Ethanol	pure alcohol
Fatigue	Lethargy
fertilization	Conception

Professional term	Equivalent consumer term
immunoglobulins	Antibodies
nasopharyngitis	common cold
neuroleptics	Antipsychotics
nutrition	Nourishment
orthostatic hypotension	postural hypotension
periodontitis	gum disease
rofecoxib	Vioxx
social care	home care
stuttering	Stammering
uncompensated care	charity care

* The CHV mentions the pairing between ethanol and drinking alcohol, but lists it as an incorrect mapping instance.

Discussion

One of the benefits of using Wikipedia as a source to identify alternate names is that popular variant names are often nominated by the community and thus mentioned in the Wikipedia article about the primary concept. As language itself evolves, new variants might be introduced,[51] and existing variants might change in popularity. Regularly updating the CHV using the latest snapshot of Wikipedia articles provides one way to keep them current and relevant. Since errors in Wikipedia articles often get corrected by other editors, periodic update of extracted pairs can therefore help eliminate erroneous instances of extracted pairs. For instance, we observed that the latest version of Wikipedia (updated after our analyses were conducted) correctly removed the mention of "radiation oncology" as a variant form for "radiology" (see Table 3, row (d.1)). In the same vein, the professional and consumer text corpora could also be frequently updated to monitor the usage of such terms in the respective communities.

The approach of using free text to compute statistics is subject to the entity disambiguation problems. For example, the term "cocci" has multiple meanings – it could be used either as a shortened term for the disease "coccidioidomycosis", or as the plural form of "coccus". Failure to disambiguate between these two concepts could lead to mislabeling. Although this is a limitation of most statistical and shallow, frequency-based approaches, such occurrences are relatively infrequent.

We have not measured the recall of such pattern-based approaches, to extract *all* instances of consumer terms or alternate variants. Further study is also needed to understand if the words used in the patterns could improve the labeling of terms as professional or consumer. For example, if the pattern is "commonly known as" or "colloquially called", it is more likely that the succeeding concept is a consumer term.

Concerns have been raised about use of Wikipedia as a resource of information in the scientific literature. Bibliometric analysis has shown an increased rate of citing Wikipedia articles in peer-reviewed health science journal publications in recent years,[55,56] and studies have found several limitations with respect to depth of discussion and readability in Wikipedia articles.[57,58] Efforts are underway to encourage medical professionals to actively contribute to Wikipedia,[59] and, in collaboration with other medical and healthcare experts and medical journals, to improve the overall quality of medical articles in Wikipedia.[60,61] Although such concerns are important issues to address in the future, they are beyond the current scope of research presented in this paper.

Conclusion

In this study, we demonstrated the effectiveness of a novel approach that uses community-generated corpora such as Wikipedia to mine pairs of professional terms and their equivalent consumer terms. We measured the propensity of

a term to be a consumer term based on its relative frequencies appearing in the consumer or professional contexts, and demonstrated how this information could be used to properly label the terms. The empirical evaluation results are promising, suggesting that the proposed approach is able to identify and differentiate consumer and professional terms from the Wikipedia corpus with high accuracy. The methods proposed in this paper can therefore be used to augment, update, and maintain existing consumer health vocabularies to enhance the performance of computational applications designed to improve the readability, parsing, and understandability of community-generated health text.

Adverse Drug Event-based Stratification of Tumor Mutations: A Case Study of Breast Cancer Patients Receiving Aromatase Inhibitors

Chen Wang, PhD, Michael T. Zimmermann, PhD, Naresh Prodduturi, Christopher G. Chute, MD, Dr.PH, Guoqian Jiang, MD, PhD
Department of Health Sciences Research, Division of Biomedical Statistics and Informatics, Mayo Clinic, Rochester, MN

Abstract

Adverse drug events (ADEs) are a critical factor for selecting cancer therapy options. The underlying molecular mechanisms of ADEs associated with cancer therapy drugs may overlap with their antineoplastic mechanisms; an aspect of toxicity. In the present study, we develop a novel knowledge-driven approach that provides an ADE-based stratification (ADEStrata) of tumor mutations. We demonstrate clinical utility of the ADEStrata approach through performing a case study of breast invasive carcinoma (BRCA) patients receiving aromatase inhibitors (AI) from The Cancer Genome Atlas (TCGA) (n=212), focusing on the musculoskeletal adverse events (MS-AEs). We prioritized somatic variants in a manner that is guided by MS-AEs codified as 6 Human Phenotype Ontology (HPO) terms. Pathway enrichment and hierarchical clustering of prioritized variants reveals clusters associated with overall survival. We demonstrated that the prediction of per-patient ADE propensity simultaneously identifies high-risk patients experiencing poor outcomes. In conclusion, the ADEStrata approach could produce clinically and biologically meaningful tumor subtypes that are potentially predictive of the drug response to the cancer therapy drugs.

1 Introduction

Adverse drug events (ADEs) have been well recognized as a cause of patient morbidity and increased health care costs in the United States. With rapid developments in genomics technology, the contribution of genetic factors to ADEs is being considered and has already influenced clinical recommendations for drug dosage and toxicity (1, 2), thus representing a major component of the movement to pharmacogenomics and individualized medicine (3, 4). Genetic susceptibility is an important feature of severe ADEs and there is considerable interest in developing genetic tests to identify at-risk patients prior to prescription (5). Preliminary studies also suggested that drug therapies based on an individual's genetic makeup may result in a significant reduction in adverse outcomes (6).

To conduct a pharmacogenomics study of an ADE, ideally, multiple sources of evidence should be integrated to fully characterize the potential pharmacogenomics mechanism relevant to the ADE. For instance, a project known as PharmGKB (7, 8), initiated by the National Institute of Health (NIH), has a mission of collecting and disseminating human-curated information about the impact of human genetic variation on drug responses. In our previous studies, we proposed a knowledge-driven framework that aims to support pharmacogenomics-target prediction of ADEs (9). In the framework, we integrated a semantically annotated literature corpus, Semantic MEDLINE, with a semantically coded ADE knowledge base known as ADEpedia (10) using a Semantic Web-based framework. We developed a knowledge-discovery approach leveraging a network-based analysis of a protein-protein interaction (PPI) network to mine the knowledge of drug-ADE-gene interactions.

The recent advances in sequencing technology have underpinned the progress in several large-scale projects to systematically compile genomic informatics related to human cancer (11, 12). A notable example is The Cancer Genome Atlas (TCGA) (13) and projects that have focused on identifying links between cancer and genomic variation. More promisingly, TCGA Pan-Cancer Project (14) has been initiated to assemble coherent datasets across tumor types, analyze the data in a consistent fashion, and finally provide comprehensive interpretation. Tumor stratification has been regarded as one of the fundamental goals of cancer informatics, enabling Pan-Cancer studies in which the molecular profiles of tumors are used to determine subtypes (15), regardless of the organ in which it is manifest. In particular, the somatic mutation profile is emerging as a rich new source of data for uncovering tumor subtypes with different causes and clinical outcomes. A network-based stratification using the knowledge of molecular signaling could produce robust tumor subtypes that are biologically informative and have a strong association to clinical outcomes and emergence of drug resistance (15).

Preliminary studies have demonstrated that the underlying molecular mechanism of common ADEs known to cancer therapy drugs may overlap with that of the efficacy of the therapeutic drugs themselves. For example, breast cancer patients receiving aromatase inhibitors (AI) have a high incidence of musculoskeletal adverse events (MS-

AEs); about half of patients treated with AIs have joint-related complaints (16, 17). Musculoskeletal complaints have been the most frequent reason given by patients on a clinical trial comparing the non-steroidal AI anastrozole with the steroidal AI exemestane as adjuvant therapy for early breast cancer (18). A case-control genome-wide association study (GWAS) from a Mayo Clinic group identified SNPs associated with MS-AEs in women treated with AIs, one of which created an estrogen response element (18). Another study in the same group at Mayo Clinic confirmed that single nucleotide polymorphisms (SNPs) in the aromatase CYP19 gene contribute to response to neoadjuvant AI therapy (19), two of which are significantly associated with both a greater change in aromatase activity after AI treatment and higher plasma estradiol levels pre- and post-AI treatment.

The objective of the present study is to develop a novel knowledge-driven approach that provides an ADE-based stratification of tumor mutations (ADEStrata). Our assumption here is that the ADE-based tumor stratification would potentially produce clinically and biologically meaningful tumor subtypes that are predictive of the drug response to the cancer therapy drugs. To test the assumption, we performed a case study of breast cancer patients receiving the AIs from TCGA. We utilized a variant prioritization tool upon the somatic mutation profiles of TCGA breast invasive carcinoma (BRCA) patients treated with three AI drugs. The phenotype input of the variant prioritization tools contains a set of MS-AEs represented by standard Human Phentoype Ontology (HPO) terms. We utilized the prioritized variants to cluster the target patients into subgroups and investigated their associations with clinical outcomes.

2 Materials and Methods

2.1 Materials

2.1.1 SIDER: A Side Effect Resource

The SIDER (SIDe Effect Resource) is a public, computer-readable side effect resource that contains reported adverse drug reactions(20). The information is extracted from public documents and package inserts; in particular, from the United States Food and Drug Administration (FDA) Structured Product Labels (SPLs). The standardized Coding Symbols for a Thesaurus of Adverse Reaction Terms (COSTART), which are part of the Unified Medical Language System (UMLS) Metathesaurus, were used as the basic lexicon of side effects. In the present study, we utilized the latest version SIDER 2 that was released on October 17, 2012.

2.1.2 HPO: Human Phenotype Ontology

The HPO project aims to provide a standardized vocabulary of phenotypic abnormalities encountered in human diseases (21). The HPO is being developed in collaboration with the OBO Foundry using information from Online Mendelian Inheritance in Man (OMIM) and medical literatures. The ontology contains more than 10,000 terms and equivalence mappings to other standard vocabularies such as MedDRA and UMLS. In the present study, we used the latest version of HPO-MedDRA mapping file that is publicly available from the HPO website (22).

2.1.3 eXtasy: A Variant Prioritization Tool

eXtasy is a pipeline developed at the University of Leuven, for ranking the likelihood that a given nonsynonymous single nucleotide variants (nSNVs) is related to given phenotype (23, 24). The pipeline utilizes a genomic data fusion methodology (25) that takes into account multiple strategies to detect the deleteriousness of mutations and prioritizes them in a phenotype-specific manner. The ultimate goal of the tool is to discriminate between putatively mildly deleterious rare variants and actual disease-causing variants. The eXtasy tool is open-source and publicly downloadable from its github site (26). The eXtasy pipeline takes a Variant Call File (VCF) and one or more gene prioritization files. Each prioritization file is pre-computed for a specific phenotype (HPO term). In the present study, we downloaded and installed the tool on a local Ubuntu server.

2.1.4 TCGA Data Portal

TCGA Data Portal provides a platform for researchers to search, download, and analyze data sets generated by TCGA (27). It contains clinical information, genomic characterization data, and high level sequence analysis of the tumor genomes. There are two data access tiers: Open Access data tier and Controlled Access. The data of more 30 tumor types are available from the data portal. As of February 2014, there are 1043 cases of breast invasive carcinoma (BRCA) with data. In the present study, we utilized the BRCA clinical data (including clinical drug data and follow-up data) and somatic mutation data through the Open Access data tier.

2.2 Methods

2.2.1 Identifying HPO ADE Terms Relevant to Aromatase Inhibitors

In the present study, we aim to conduct variant prioritization in a manner that can be guided by the ADEs relevant to AI drugs. In other words, the ADEs induced by AI drugs are treated as the phenotypes required by the eXtasy tool. In order to enable the use of the eXtasy tool for variant prioritization in a phenotype-specific manner, we need to identify the phenotypes that are represented in HPO terms.

We first mapped the ADE terms represented in MedDRA UMLS concept unique identifiers (CUIs) from the SIDER 2 database file to the HPO terms using an HPO-MedDRA mapping file produced by HPO development team. Second, we annotated those HPO terms with a flag using the eXtasy HPO term list to indicate whether a HPO-based ADE term can be processed by eXtasy or not. Third, we retrieved those entries (with drug-ADE pairs) using the drug names “anastrozole”, “exemestane” and “letrozole” which are the third-generation AI drugs. We reviewed all the ADE terms and identified those ADE terms belonging to musculoskeletal adverse events (MS-AEs) and their HPO term annotations.

2.2.2 Identifying Patient Cohorts by AI Drugs and Somatic Mutations from TCGA

We utilized the clinical drug file of the BRCA patients from TCGA data portal through its Open-Access HTTP Directory. The spelling corrections were taken for all variants of the three drugs to maximize the sample size of the patient cases. We then identified a set of patient cases (represented by patient barcodes) that were prescribed for the three AI drugs (AI cases).

We also downloaded the somatic mutation file of the BRCA patients from TCGA data portal in a Mutation Annotation Format (MAF). The format is a tab-delimited file containing somatic mutations for each patient. As eXtasy requires a VCF file as input, we converted the MAF file into a collection of VCF files. Each VCF file contains somatic mutations for a single patient tumor sample. We combined all VCF files for all AI cases into a single VCF file using the patient barcodes identified in the step above.

2.2.3 Variant Prioritization Using HPO ADE Terms

As mentioned above, we installed an instance of the eXtasy tool in a local server and ran the tool with a custom Ruby script. The input consists of a VCF file (produced in the Section 2.2.2) and a set of pre-computed gene prioritization files for those phenotypes represented by the HPO ADE terms of interest (identified in the Section 2.2.1). The output is a file with scores for the individual variants’ likelihood of impacting an individual HPO term. Order statistics (25) and aggregate scores are generated and range from 0 to 1, where 0 is likely to be disease-causing and 1 unlikely (in contrast with the normal eXtasy scores). This is a pseudo p-value that represents the probability that a variant is high-ranking in all different phenotypes given the null-hypothesis of random rankings. To understand how the variants affect function, we first classified the input variants into three functional impact categories, calling a variant “high” if it is a frameshift, nonsense, nonstop, or splice-site; and “medium” if it is a missense; and “silent” if it is a mutation not causing protein coding changes. And then we analyzed the function of those variants scored by eXtasy for AI-related HPO terms.

2.2.4 Tumor Mutation Stratification and Clinical Outcome Association Studies

We first selected statistically significant variants based on the eXtasy order statistics (pseudo p-value <0.05). Second, we aggregated genes affected by these prioritized variants across 1,320 canonical pathways collected from the Molecular Signature Database (MSigDB) (28, 29). In order to reduce false discoveries, multiple criteria were applied to further filter out less relevant pathways (binomial distribution p-value >0.05) or pathways containing too few genes (<10 genes). We excluded pathways with less than 10 genes, based on the consideration that small pathways are often subcomponents of larger pathways, and inclusion of them tends to introduce unnecessary redundancy. Third, we performed hierarchical clustering to highlight pathway-level patterns among AI-treated patients.

We used overall survival (OS) time (months) as a clinical endpoint to measure the outcome of TCGA patients in the identified cohort. We performed both univariate analysis and multivariate cox-regression to assess the association of clusters (produced by hierarchical clustering) with survival. In multivariate analysis, patient age and tumor stage were adjusted for to evaluate the independent contribution of each cluster. We also analyzed the distribution of patient age and tumor stage in the clusters identified.

3 Results

Out of 4,492 unique MedDRA terms represented by the UMLS CUIs from the SIDER database file, 2,827 (62.9%) MedDRA terms had mappings to 1,491 unique HPO terms. Out of the 1,491 HPO terms, 844 (56.6%) HPO terms are included in the eXtasy phenotype list. We identified 6 unique HPO terms representing the MS-AEs relevant to three AI drugs. The 6 HPO terms are *HP:0003418|Back pain, HP:0002653|Bone pain, HP:0003011|Abnormality of musculature, HP:0001369|Arthritis, HP:0009763|Limb pain, and HP:0002758|Osteoarthritis*. Table 1 shows the SIDER database entries with HPO terms identified for the musculoskeletal adverse events (MS-AEs) relevant to three AI drugs.

Table 1. Entries with HPO terms identified for the musculoskeletal adverse events (MS-AEs) relevant to three AI drugs

Drug label	Meddra umls cui	Meddra label	HPO id	HPO label	HPO Term in eXtasy
anastrozole	C0004604	Back pain	HP:0003418	Back pain	YES
anastrozole	C0151825	Bone pain	HP:0002653	Bone pain	YES
anastrozole	C0026857	Musculoskeletal disorder	HP:0003011	Abnormality of musculature	YES
anastrozole	C0003864	Arthritis	HP:0001369	Arthritis	YES
exemestane	C0004604	Back pain	HP:0003418	Back pain	YES
exemestane	C0151825	Bone pain	HP:0002653	Bone pain	YES
exemestane	C0030196	Pain in extremity	HP:0009763	Limb pain	YES
exemestane	C0026857	Musculoskeletal disorder	HP:0003011	Abnormality of musculature	YES
exemestane	C0029408	Osteoarthritis	HP:0002758	Osteoarthritis	YES
letrozole	C0004604	Back pain	HP:0003418	Back pain	YES
letrozole	C0026857	Musculoskeletal disorder	HP:0003011	Abnormality of musculature	YES
letrozole	C0151825	Bone pain	HP:0002653	Bone pain	YES
letrozole	C0030196	Pain in extremity	HP:0009763	Limb pain	YES
letrozole	C0003864	Arthritis	HP:0001369	Arthritis	YES

Using the clinical drug file of TCGA BRCA patients, we identified a cohort of 212 patients who were prescribed with one of the three AI drugs (AI cases).

The algorithm eXtasy ranks coding variants according to their probability of being related to a given phenotype. We found that 23.8% of the input variants are silent and are ignored by eXtasy, while 11.6% are of high impact (see section 2.2.3) and almost assuredly affect the normal physiologic function of the affected gene. Of the variants scored by eXtasy for AI-related HPO terms, 43% are highly conserved among placental mammals. Variants were prioritized for each patient across the MS-AE phenotypes represented by 6 HPO terms (listed in Table 1), producing aggregate prioritization scores (max and order statistics). Table 2 lists the top 20 prioritized variants.

Table 2. Top 20 variants prioritized for the MS-AE phenotypes using the eXtasy in the AI cases

From the eXtasy output for the AI cases, 2,164 statistically significant variants were selected for pathway enrichment and clustering analysis. Among 1,320 canonical pathways, 63 of them passed the filtering criteria defined in section 2.2.4. By hierarchical clustering, 3 distinct patient clusters, organized by pathways (affected by prioritized variants), were identified and are displayed in Figure 1 containing 91, 60, and 22 patients each. Patients in Cluster 1 exhibit relatively silent pathway aberrations, while Cluster 2 and Cluster 3 have much stronger pathway activities. A summary of the 63 selected pathways, enriched in MS-AE relevant variants, can be found in Supplemental Table 1 posted at http://catargets.org.

Table 3 shows the results of the univariate and multivariate cox-regression analysis for the three clusters. We found that although Cluster 3 has a relatively small number of patients, the cluster is significantly association with poorer survival time in both univariate and multivariate analysis. Table 4 shows the distribution of age and stage in the 3 clusters identified. There is no significant association between the 3 clusters and age/stage, although we noticed that Cluster 3 is enriched with more Stage 2 patient cases.

Figure 2 shows a Kaplan-Meier plot of survival time for the 3 clusters, derived from our pathway-level analysis. Interestingly, Cluster 2 does not have a significantly altered survival time, despite its similarity to Cluster 3. The exception is for a few activated pathways responsible for DNA damaging repair and apoptosis. In addition, we observed that many patients in Cluster 1 have somatic variants associated with ATM/thyroid pathways, while Cluster 2 has many other pathway features but lacks the ATM/thyroid pathway enrichment. Cluster 3, however, has the pathway features of both Cluster 1 and Cluster 2. This “two hits” pattern may account for the worse survival outcome associated with Cluster 3.

4 Discussion

In this study, we demonstrated that the ADE-based tumor stratification could produce clinically and biologically meaningful tumor subtypes that are potentially predictive of the drug response to the cancer therapy drugs. The preliminary results from the case study of TCGA breast cancer patients receiving AI drugs are very promising. We consider that our study approach and results have several important implications in terms of how to further understanding of disease, drug action or to improve treatment outcome. First, it would be possible that new patients can be assigned to different groups to inform clinical decision-making. Second, our approach could be potentially used in prediction of treatment outcomes or probability of ADEs based on tumor genome. Third, it would be possible that our study results could be used to gain a greater understanding of mechanism of action of targeted drugs or underlying causes of ADEs.

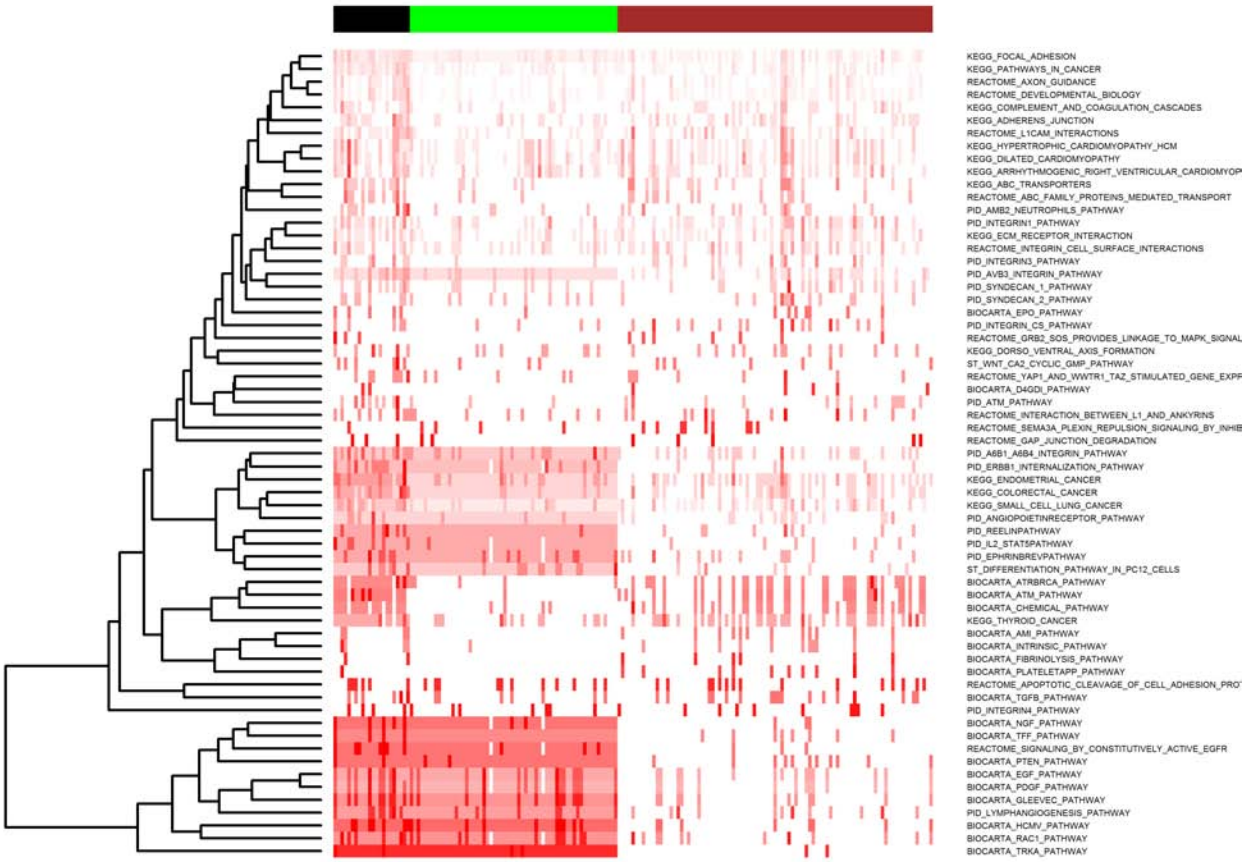

Figure 1. This ordered heatmap shows pathway-level clustering of 173 patients treated with AI across 63 pathways-enriched MS-AE relevant variants. The color of heatmap from white to red indicates low to high percentages (0% to 100%) of genes affected by MS-AE relevant variants. Column color-bar on top of the heatmap indicates three clusters of samples: Cluster 1 (brown), Cluster 2 (green) and Cluster 3 (black). Note that the number of the patients (n=173) with pathway enrichment is less than total number of the identified cohort (n=212) is because not all patients have prioritized variants listed.

Table 3. The univariate and multivariate cox-regression analysis results of cluster labels. In multivariate analysis, patient age and tumor stage were adjusted for to determine the independent contribution of cluster membership. * denotes p<0.05.

	Univariate analysis		***Multivariate analysis***	
	p-value	**HR [95% CI]**	**p-value**	**HR [95% CI]**
Cluster 2 (n=60) (Cluster 1 as ref)	0.63	0.57 [0.06, 5.55]	0.64	0.57 [0.06, 5.76]
Cluster 3 (n=22) (Cluster 1 as ref)	0.03*	5.03 [1.13, 22.55]	0.04*	4.86 [1.07, 22.161]
Overall model (log-rank test)	0.02*	NA	0.07	NA

Table 4. The disribution of age and stage in the 3 clusters identified. * p-value for age vs. cluster association was computed using ANOVA test; p-value for stage vs. cluster association was computed using Fisher's exact test.

One of the key components of our approach is to leverage known ADE knowledge for tumor stratification. We found that a semantically coded ADE knowledge base is extremely useful for extracting known ADEs relevant to target drugs. We utilized the SIDER ADE dataset, in which the ADEs are annotated with the MedDRA codes

represented by UMLS CUIs. In addition, the HPO team has produced a mapping file between MedDRA UMLS CUIs and HPO terms. These standard codes facilitated our ability to integrate and identify ADE terms across different datasets. For example, in the present study, eXtasy requires HPO terms as phenotype input and we were able to identify those MS-AE terms from the SIDER dataset represented in UMLS CUIs.

Use of standard phenotype/diagnosis codes enables the potential of an automatic mechanism to retrieve a set of ADE codes for a specific patient or disease domain. Although we manually identified and retrieved 6 ADE codes related to MS-AEs in this study, it would be valuable to build a valueset definition mechanism based on the semantic hierarchical relationship (eg, parent-child relation) asserted in standard terminologies, ideally through standard terminology services such as the recent development of the OMG/HL7 standard - common terminology services 2 (CTS2) (30, 31). Drug data normalization is another typical use case for utilizing standard terminologies and an important prerequisite for accurate ADE association. We noticed that the scope of drug name normalization must move beyond synonym mapping (itself a difficult task) as commonly used public resources also contain spelling errors and other types of irregularities. For example, from TCGA clinical drug data, the names "CYOTXAN", "CYTOXAN", "CYTOXEN", "CYCLOPHASPHAMIDE", "CYCLOPHOSPHAMID" are used to record the drug "Cyclophosphamide". A more detailed investigation on drug data normalization is beyond the scope of the present study and is addressed in a separate paper (32).

We also found that the severity and frequency of the ADEs are important factors for enabling our tumor stratification approach. As we mentioned in the Introduction section, breast cancer patients receiving AIs have a high incidence of MS-AEs; about half of patients treated with AIs have joint-related complaints (16, 17). Musculoskeletal complaints have been the most frequent reason given by patients on a clinical trial comparing the non-steroidal AI anastrozole with the steroidal AI exemestane as adjuvant therapy for early breast cancer (18). We believe that an ADE knowledge base with such severity and frequency information would be greatly useful in selecting the ADE phenotypes for tumor stratification, which is one of the goals of our ongoing ADEpedia project. In a previous study, we have developed an approach to build a severe ADE knowledge base based on the FDA Adverse Event Reporting System (AERS) reporting data (33). In this work, we propose a computational approach to screen genomic variants from individual patients and relate them to the probability of that patient experiencing an ADE while on a particular treatment.

In this study, we utilized the variant prioritization tool eXtasy for two primary reasons. First, eXtasy uses summary statistics of multiple criteria to evaluate the importance and contextual relevance of nonsynonymous SNVs according to conservation, interaction networks derived from experimental and knowledge databases, gene ontology, etc. This provides a succinct computable mechanism for aggregating knowledge associated with the nonsynonymous SNVs. Second, variant prioritization is guided by specific phenotypes, which in particular are organized using standard HPO terms. This provides a standard interface, allowing us to use the ADEs in HPO terms as input to the tool. In the future, we plan to evaluate the eXtasy tool in comparison with other variant prioritization algorithms. Pre-filtering the variants to only those we believe likely to affect function may be worth exploring, but may suffer from eXtasy having less power to make an appropriate association. The eXtasy algorithm only utilizes non-synonymous variants; all silent mutations (about 23.8%) are filtered out. It is intuitive that those affecting splicing, frameshift, or truncating would be more impactful than missense variants, but they are also more rare.

The rich cancer genomic data produced by TCGA Research Network provides a major opportunity to develop an integrated picture of commonalities, differences and emergent themes across tumor lineages. TCGA Pan-Cancer project (14) envisions that there are six types of omics characterization that create a data stack for maximizing the potential of integrative analysis. The six types comprise mutation, copy number, gene expression, DNA methylation, MicroRNA, reverse-phase proteomic arrays (RPPA) and clinical data. Hofree, *et al*, introduced a network-based stratification (NBS) method to integrate somatic tumor genomes with gene networks, which could identify subtypes in ovarian, uterine and lung cancer cohorts from TCGA (15). They demonstrated that the subtypes are predictive of clinical outcomes such as patient survival, response to therapy or tumor histology. By integrating mRNA, microRNA (miRNA), and DNA methylation next-generation sequencing data from TCGA, Volinia, *et al*. performed survival analysis on a cohort of 466 patients with primary invasive ductal carcinoma (IDC), and produced an integrated RNA signature that has been demonstrated prognostic to the IDC patients (34). The novelty of the present study is to build a tumor stratification method that utilizes the ADE-based variant prioritization, with the assumption that the underlying molecular mechanism of common ADEs known to cancer therapy drugs may overlap with that of the efficacy of the therapeutic drugs themselves, or have common indications. Although not presently utilizing the full data stack, our approach did identify subtypes predictive of patient survival time. We believe that an integrative

analysis with more omics data types would provide greater insights into the underlying biological mechanisms of the identified subtypes.

Since the impact of an individual variant is often difficult to interpret, in particular those only mutated in one (or a few) patient(s), directly comparing the landscape of genomic differences across patients is of great difficulty. To address the challenge, we performed a pathway enrichment analysis with multiple criteria and identified 63 canonical pathways that are highly related to the prioritized variants selected using the MS-AE phenotypes. In general, the definition of a pathway is a convenient abstraction for underlying molecular regulations, but cross-talk between pathways is often observed. Capitalizing upon cross-talk, we were able to perform a hierarchical clustering analysis to highlight the pathway-level patterns for the somatic variants among AI treated patients. Three clusters were identified, in which we found that the pathway pattern in Cluster 1 demonstrated its own characteristics in terms of pathway aberrations in comparison with the pathway patterns in Cluster 2 and 3. More promisingly, clinical outcome association analysis demonstrated that the survival time among the three clusters is significantly different, with Cluster 3 having the worst survival time (see Figure 2). We find that Clusters 2 and 3 have a similar pathway pattern in general, except for a few activated pathways responsible for DNA damaging repair and apoptosis. This perhaps represents a "two hits" pattern for Cluster 3 that may be responsible for the poorer survival outcome. We consider that our pathway-based clustering approach would make the findings from clinical outcome association studies more interpretable.

In summary, we developed a novel knowledge-driven approach that provides an ADE-based stratification of tumor mutations. We demonstrated that the prediction of per-patient ADE propensity simultaneously identifies high-risk patients experiencing poor outcomes. We plan to evaluate and validate our approach by incorporating more other data types (eg, germline variants) and other tumor types, and explore its potential in enabling pan-cancer studies in the future. The datasets and supplementary results produced by the study are publicly available at http://catargets.org.

Clinical Risk Prediction by Exploring High-Order Feature Correlations

Fei Wang, Ping Zhang, Xiang Wang, Jianying Hu
IBM T. J. Watson Research Center, Yorktown Heights, NY
{fwang,ping,wangxi,jyhu}@us.ibm.com

Abstract

Clinical risk prediction is one important problem in medical informatics, and logistic regression is one of the most widely used approaches for clinical risk prediction. In many cases, the number of potential risk factors is fairly large and the actual set of factors that contribute to the risk is small. Therefore sparse logistic regression is proposed, which can not only predict the clinical risk but also identify the set of relevant risk factors. The inputs of logistic regression and sparse logistic regression are required to be in vector form. This limits the applicability of these models in the problems when the data cannot be naturally represented vectors (e.g., medical images are two-dimensional matrices). To handle the cases when the data are in the form of multi-dimensional arrays, we propose *HOSLR*: High-Order Sparse Logistic Regression, which can be viewed as a high order extension of sparse logistic regression. Instead of solving one classification vector as in conventional logistic regression, we solve for K classification vectors in *HOSLR* (K is the number of modes in the data). A block proximal descent approach is proposed to solve the problem and its convergence is guaranteed. Finally we validate the effectiveness of *HOSLR* on predicting the onset risk of patients with Alzheimer's disease and heart failure.

1 Introduction

Predictive modeling of clinical risk, such as disease onset [1] or hospitalization [2], is an important problem in medical informatics. Effective risk prediction can be very helpful for the physician to make proper decision and provide the right service at point-of-care.

Typically we need three steps to perform patient clinical risk prediction:

1. Collecting all potential risk factors from patient historical data and utilizing them to properly represent each patient (e.g., as a vector [1][3]).
2. Identifying important risk factors from the risk factor pool collected in the first step, such that the value change of the selected risk factors could generate big impact on the predicted risk.
3. Training a proper predictive model based on the patients represented with the selected risk factors from the second step. Such model will be used to score the clinical risk of new testing patients.

One representative clinical risk prediction work that follows those three steps is the work by Sun *et al.* [1], where the goal is to predict the onset risk for potential heart failure patients. The authors first collect all potential risk factors from the two year patient electronic health records, and then designed an scalable orthogonal regression method to identify important risk factors, which will be used to train a logistic regression model for risk prediction at last. The authors showed that they can achieve the state-of-the-art performance as well as identify clinically meaningful risk factors for heart failure.

Note that in practice, depending on the concrete risk factor identification method and predictive model, step 2 and 3 could be combined into one step, i.e., a unified model can be constructed for both prediction and risk factor identification (e.g., LASSO [4]). This will make the constructed model more integrative and interpretable. Sparse Logistic Regression [5] is one such model. As is known to all that logistic regression is a popular model for clinical risk prediction [6] [1][3]. However, the pool of potential risk factors is usually very large and noisy, which would affect the efficiency and performance of predictive modeling. The main difference between sparse and convectional logistic regression is it adds an one norm regularizer on the model coefficients to encourage the model sparsity, so that only

those *important* risk factors will contribute to the final predictions. In recent years people have also been doing research on constructing different regularization terms to enforce different sparsity structures on the model coefficients, such as the ℓ_p norm [7], group sparsity [8] and elastic net regularization [9].

One limitation of the existing sparse logistic regression type of approaches is that they assume vector based inputs, which means that we need to have a vector based representation for each patient before we can use those methods to evaluate the patient's clinical risk. However, we are in the era of *big data* with *variety* as one representative characteristic, so does medical data, i.e., there are many medical data are not naturally in vector form. For example, typical medical images (e.g., X-Ray and MRI) are two dimensional matrices, with some more advanced medical imaging technologies can even generate three-dimensional image sequences (e.g., functional Magnetic Resonance Imaging (fMRI)). In a recent paper, Ho *et al*. [10] proposed a *tensor* (which can be viewed as high order generalization of matrix) based representation of patient Electronic Health Records (EHRs) to capture the interactions between different *modes* in patient EHRs. For example, medication order information for every patient could be captured by a 2nd order tensor with 2 modes, where each mode is an aspect of a tensor: a) medication and b) diagnosis. With such a representation we can take into consideration the correlation between diagnosis and drugs when predicting the patient risk. If there are more inter-correlated modes in the data then we will need to represent the patient in higher order tensors. In these cases, if we still want to apply logistic regression one straightforward way is to stretch those matrices and tensors into vectors as people did in image processing, but this will lose the correlation information among different dimensions. Moreover, after stretching the dimensionality of the data objects will become very high, which will make traditional sparse logistic regression inefficient.

In recent years, there has been a lot of research on extending traditional vector based approaches to 2nd (matrix based) or higher order (tensor based) settings. Two representative examples are two-dimensional Principal Component Analysis (PCA) [11] and Linear Discriminant Analysis [12], which have been found to be more effective on computer vision tasks compared to traditional vector based PCA and LDA. Recently, Huang and Wang [13] developed a matrix variate logistic regression model and applied it in electroencephalography data analysis. Tan *et al.* [14] further extended logistic regression to tensor inputs and achieved good performance in a video classification task.

In this paper, we propose *HOSLR*, a *H*igh-*O*rder *S*parse *L*ogistic *R*egression method that can perform prediction based on matrix or tensor inputs. Our model learns a linear decision vector on every mode of the input, and we added an ℓ_1 regularization term on each decision vector to encourage sparsity. We developed a *Block Proximal Gradient* (BPG) [15] method to solve the problem iteratively. The convergence of the proposed algorithm can be guaranteed by the Kurdyka–Lojasiewicz inequality [16] (for proof details please see a more technical version of this paper [17]). Finally we validate the effectiveness of our algorithm on two real world medical scenarios on the risk prediction of patients with Alzheimer's Disease and Heart Failure.

The rest of this paper is organized as follows. Section 2 reviews some related works. The details along with the convergence analysis of *HOSLR* is introduced in Section 3. Section 4 presents the experimental results, followed by the conclusions in Section 5.

2 Related Work

Logistic regression [18] is a statistical prediction method that has widely been used in medical informatics [1][6][19]. Suppose we have a training data matrix $\mathbf{X} = [\mathbf{x}_1, \mathbf{x}_2, \cdots, \mathbf{x}_n] \in \mathbb{R}^{d\times n}$, where $\mathbf{x}_i \in \mathbb{R}^d$ $(1 \leqslant i \leqslant n)$ is the i-th training data vector with dimensionality d, and associated with each $\mathbf{x}_i$ we also have its corresponding label $y_i \in \{+1, -1\}$. The goal of logistic regression is to train a linear decision function $f(\mathbf{x}) = \mathbf{w}^\top \mathbf{x} + b$ to discriminate the data in class +1 from the data in class -1 by minimizing the following logistic loss

$$\ell_{org}(\mathbf{w}, b) = \frac{1}{n}\sum_{i=1}^{n} \log\left[1 + \exp(-y_i(\mathbf{w}^\top \mathbf{x}_i + b))\right] \tag{1}$$

where $\mathbf{w} \in \mathbb{R}^d$ is the decision vector and b is the bias. They can be learned with gradient descent type of approaches.

In many medical informatics applications, the data vectors $\{\mathbf{x}_i\}_{i=1}^n$ are sparse and high-dimensional (e.g., each patient could be a tens of thousands dimensional vector with bag-of-feature representation [1]). To enhance the interpretability

of the model in these scenarios, we can minimize the following ℓ_1-regularized logistic loss

$$\ell_{sp}(\mathbf{w}, b) = \frac{1}{n}\sum_{i=1}^{n} \log\left[1 + \exp(-y_i(\mathbf{w}^\top \mathbf{x}_i + b))\right] + \lambda\|\mathbf{w}\|_1 \tag{2}$$

where $\|\cdot\|_1$ is the vector $\ell 1$ norm and $\lambda > 0$ is a factor trading off the prediction accuracy and model sparsity. The resultant model is usually referred to as sparse logistic regression model [5][20]. Compared with the conventional logistic regression model obtained by minimizing $\mathcal{J}_{org}$, the $\mathbf{w}$ obtained by minimizing $\mathcal{J}_{sp}$ is sparse thanks to the ℓ_1 norm regularization. In this way, we can not only get a predictor, but also know what are the feature dimensions that are important to the prediction (which are the features with nonzero classification coefficients).

Sparse logistic regression has widely been used in health informatics because it can achieve a good balance between model accuracy and model interpretability. For example, sparse logistic regression has been used in the prediction of Leukemia [21], Alzheimer's disease [22] and cancers [23]. In recent years people also designed different regularization terms [7][8][9] to enforce more complex sparsity patterns on the learned model. However, all these works require a vector based data representations. Under this framework, if the data naturally come as tensors (like medical imaging), we need to first stretch them into vectors before we can apply sparse logistic regression. This may lose the correlation structure among different modes in the original data, while for the *HOSLR* method proposed in this paper, we directly work with data in tensor representations. Fig.1 provides a graphical illustration on the difference of traditional vector based logistic regression and high order logistic regression when working on multi-dimensional data.

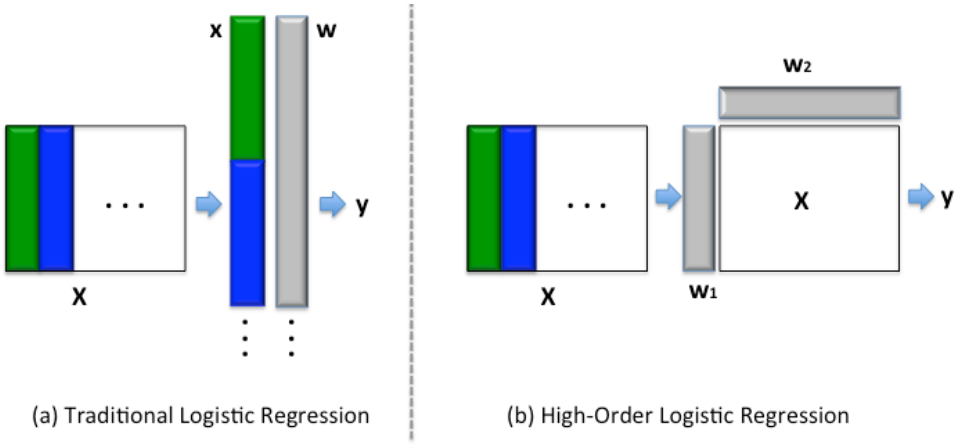

Figure 1: Traditional vector based logistic regression and high-order logistic regression work on multi-dimensional data.

3 Methodology

We introduce the details of *HOSLR* in this section. First we will formally define the problem.

3.1 Problem Statement

Without the loss of generality, we assume each observation is a tensor $\mathcal{X}^i \in \mathbb{R}^{d_1 \times d_2 \times \cdots d_K}$, suppose its corresponding response is $y^i \in \{0, 1\}$, then *HOSLR* assumes

$$y^i \leftarrow \mathcal{X}^i \times_1 \mathbf{w}^1 \times_2 \mathbf{w}^2 \cdots \times_K \mathbf{w}^K + b \tag{3}$$

where $\times_k$ is the mode-k product, and $\mathbf{w}^k \in \mathbb{R}^{d_k \times 1}$ is the prediction coefficients on the k-th dimension. Then

$$\mathcal{X}^i \times_1 \mathbf{w}^1 \times_2 \mathbf{w}^2 \cdots \times_K \mathbf{w}^K = \sum_{i_1=1}^{d_1}\sum_{i_2=1}^{d_2}\cdots\sum_{i_K=1}^{d_K} w^1_{i_1} w^2_{i_2} \cdots w^K_{i_K} X^i_{i_1 i_2 \cdots i_K} \tag{4}$$

Let $\mathcal{W} = \{\mathbf{w}_1, \mathbf{w}_2, \cdots, \mathbf{w}_K\}$ be the set of prediction coefficient vectors. The loss we want to minimize is

$$\begin{aligned} \ell(\mathcal{W}, b) &= \frac{1}{n}\sum_{i=1}^{n} \ell(\mathcal{X}_i, y_i, \mathcal{W}) = \frac{1}{n}\sum_{i=1}^{n} \ell(y_i, \mathcal{X}^i \times_1 \mathbf{w}^1 \times_2 \mathbf{w}^2 \cdots \times_K \mathbf{w}^K + b) \\ &= \frac{1}{n}\sum_{i=1}^{n} \ell(y_i, f_{(\mathcal{W},b)}(\mathcal{X}^i)) \end{aligned}$$

where for notational convince, we denote

$$f_{(\mathcal{W},b)}(\mathcal{X}^i) = \mathcal{X}^i \times_1 \mathbf{w}^1 \times_2 \mathbf{w}^2 \cdots \times_K \mathbf{w}^K + b \tag{5}$$

The loss function we considered in this paper is *Logistic Loss*:

$$\ell_l(\mathcal{W}, b) = \log[1 + \exp(-y_i f_{(\mathcal{W},b)}(\mathcal{X}^i))] \tag{6}$$

We also introduce the regularization term

$$\mathcal{R}(\mathcal{W}) = \mathcal{R}_1(\mathcal{W}) + \mathcal{R}_2(\mathcal{W}) = \sum_{k=1}^{K} \lambda_k \|\mathbf{w}^k\|_1 + \frac{1}{2}\sum_{k=1}^{K} \mu_k \|\mathbf{w}^k\|_2^2 \tag{7}$$

which is usually referred to as *elastic net* regularization [24]. This regularizer is a combination of ℓ_1 and ℓ_2 norm regularizations, thus it can achieve better numerical stability and reliability [24]. Then the optimization problem we want to solve is

$$\min_{\mathcal{W}} \mathcal{J}(\mathcal{W}, b) = \ell(\mathcal{W}, b) + \mathcal{R}(\mathcal{W}) \tag{8}$$

We adopt a *Block Coordinate Descent* (BCD) procedure to solve the problem. Starting from some initialization $(\mathcal{W}_{(0)}, b_{(0)})$, at the i-th step of the t-th round of updates, we update $(\mathbf{w}^k_{(t)}, b_{(t)})$ by

$$(\mathbf{w}^k_{(t)}, b_{(t)}) = \arg\min_{(\mathbf{w},b)} \left[\ell(\mathcal{W}^{1\sim(k-1)}_{(t)}, \mathbf{w}, \mathcal{W}^{(k+1)\sim K}_{(t-1)}, b) + \lambda_k \|\mathbf{w}\|_1 + \frac{\mu_k}{2}\|\mathbf{w}\|_2^2\right]$$

where $\mathcal{W}^{1\sim(k-1)}_{(t)} = \left\{\mathbf{w}^1_{(t)}, \mathbf{w}^2_{(t)}, \cdots, \mathbf{w}^{k-1}_{(t)}\right\}$ and $\mathcal{W}^{(k+1)\sim K}_{(t-1)} = \left\{\mathbf{w}^{k+1}_{(t-1)}, \mathbf{w}^{k+2}_{(t-1)}, \cdots, \mathbf{w}^{K}_{(t-1)}\right\}$.

Algorithm 1 Block Coordinate Descent Procedure

Require: Data set $\{\mathcal{X}_i, y_i\}_{i=1}^n$, Regularization parameters $\{\lambda_k, \mu_k\}_{k=1}^K$
1: **Initialization**: $(\mathcal{W}_{(0)}, b_{(0)})$, $t = 0$
2: **while** Not Converge **do**
3: **for** $k = 1 : K$ **do**
4: Update $(\mathbf{w}^k_{(t)}, b_{(t,k)})$ by solving problem (9)
5: $t = t + 1$
6: **end for**
7: **end while**

3.2 Proximal Gradient Descent

Algorithm 2 summarized the whole algorithmic flow of our algorithm, where $\alpha^k_{(t)} = \lambda_k/(\tau^k_{(t)} + \mu_k)$ and $\mathcal{S}_{\alpha^k_{(t)}}$ is the component-wise shrinkage operator defined as

$$\left(\mathcal{S}_{\alpha^k_{(t)}}(\mathbf{v})\right)_i = \begin{cases} v_i - \alpha^k_{(t)}, & \text{if } v_i > \alpha^k_{(t)} \\ v_i + \alpha^k_{(t)}, & \text{if } v_i < -\alpha^k_{(t)} \\ 0, & \text{if } |v_i| \leqslant |\alpha^k_{(t)}| \end{cases} \tag{9}$$

At each iteration the most time consuming part is evaluating the gradient, which takes $O(n\prod_{i=1}^K d_i)$ time, that is linear with respect to data set size and data dimension. The detailed algorithm derivation can be referred to [17].

Algorithm 2 Block Proximal Gradient Descent for Multilinear Sparse Logistic Regression

Require: Data set $\{\mathcal{X}_i, y_i\}_{i=1}^n$, Regularization parameters $\{\lambda_k, \mu_k\}_{k=1}^K$, $r_0 = 1$, $\delta_\omega < 1$

Initialization: $(\mathcal{W}_{(0)}, b_{(0)})$, $t = 1$
while Not Converge **do**
  for $k = 1 : K$ **do**
    Compute $\tau_{(t)}^k$ with $\tau_{(t)}^k = \frac{\sqrt{2}}{n} \sum_{i=1}^n \left(\left\| \nabla_{\mathbf{w}^k}^{(t,k)} f_{(\mathcal{W},b)}(\mathcal{X}^i) \right\|_2 + 1 \right)^2$
    Compute $\omega_{(t)}^k$ with $\omega_{(t)}^k = \min\left(\omega_{(t)}, \delta_\omega \sqrt{\frac{\tau_{(t-1)}^k}{\tau_{(t)}^k}}\right)$
    Compute $\widetilde{\mathbf{w}}_{(t)}^k$ with $\widetilde{\mathbf{w}}_{(t)}^k = \mathbf{w}_{(t-1)}^k + \omega_{(t)}^k(\mathbf{w}_{(t-1)}^k - \mathbf{w}_{(t-2)}^k)$
    Update $\mathbf{w}_{(t)}^k$ by $\mathbf{w}_{(t)}^k = \mathcal{S}_{\alpha_{(t)}^k}\left(\frac{\tau_{(t)}^k \widetilde{\mathbf{w}}_{(t)}^k - \nabla_{\mathbf{w}^k} \ell_{(t)}^k(\widetilde{\mathbf{w}}_{(t)}^k, b_{(t,k-1)})}{\tau_{(t)}^k + \mu_k}\right)$
    Compute $\widetilde{b}_{(t,k)}$ with $\widetilde{b}_{(t,k)} = b_{(t,k-1)} + \omega_{(t)}^k(b_{(t,k-1)} - b_{(t,k-2)})$
    Update $b_{(t,k)}$ by $b_{(t,k)} = \widetilde{b}_{t,k} - \frac{1}{\tau_{(t)}^k} \nabla_b \ell_{(t)}^k(\mathbf{w}_{(t)}^k, \widetilde{b}_{(t,k)})$
  end for
  if $\ell(\mathcal{W}_{(t-1)}, b_{(t-1,K)}) \leqslant \ell(\mathcal{W}_{(t)}, b_{(t,K)})$ **then**
    Reupdate $\mathbf{w}_{(t)}^k$ and $b_{(t,k)}$ using $\mathbf{w}_{(t)}^k = \mathcal{S}_{\alpha_{(t)}^k}\left(\frac{\tau_{(t)}^k \widetilde{\mathbf{w}}_{(t)}^k - \nabla_{\mathbf{w}^k} \ell_{(t)}^k(\widetilde{\mathbf{w}}_{(t)}^k, b_{(t,k-1)})}{\tau_{(t)}^k + \mu_k}\right)$ and $b_{(t,k)} = \widetilde{b}_{t,k} - \frac{1}{\tau_{(t)}^k} \nabla_b \ell_{(t)}^k(\mathbf{w}_{(t)}^k, \widetilde{b}_{(t,k)})$, with $\widetilde{\mathbf{w}}_{(t)}^k = \mathbf{w}_{(t-1)}^k$ and $\widetilde{b}_{(t,k)} = b_{(t,k-1)}$
  end if
  $t = t + 1$
end while

4 Experiments

In this section we will present the experimental results on applying *HOSLR* to predict the onset risk of potential Alzheimer's Disease patients from their fMRI images, and the onset risk of potential heart failure patients from their EHR data.

4.1 Experiments on Predicting the Onset Risk of Alzheimer's Disease

Alzheimer's disease (AD) is the most common form of dementia. It worsens as it progresses and eventually leads to death. There is no cure for the disease. AD is usually diagnosed in elder people (typically over 65 years of age), although the less-prevalent early-onset Alzheimer's can occur much earlier. There are currently more than 5 million Americans living with Alzheimer's disease and that number is poised to grow to as many as 16 million by 2050. The care for has been the country's most expensive condition, which costs the nation $203 billion annually with projections to reach $1.2 trillion by 2050 [25].

Early detection of AD is of key importance for its effective intervention and treatment, where *functional magnetic resonance imaging or functional MRI* (fMRI) [26] is an effective approach to investigate alterations in brain function related to the earliest symptoms of Alzheimer's disease, possibly before development of significant irreversible structural damage.

In this set of experiment, we adopted a set of fMRI scans collected from real clinic cases of 1,005 patients [27], whose cognitive function scores (semantic, episodic, executive and spatial - ranges between -2.8258 and 2.5123) were also acquired at the same time using a cognitive function test. There are three types of MRI scans that were collected from the subjects: (1) FA, the fractional anisotropy MRI gives information about the shape of the diffusion tensor at each voxel, which reflects the differences between an isotropic diffusion and a linear diffusion; (2) FLAIR, Fluid attenuated inversion recovery is a pulse sequence used in MRI, which uncovers the white matter hyperintensity of the brain; (3)

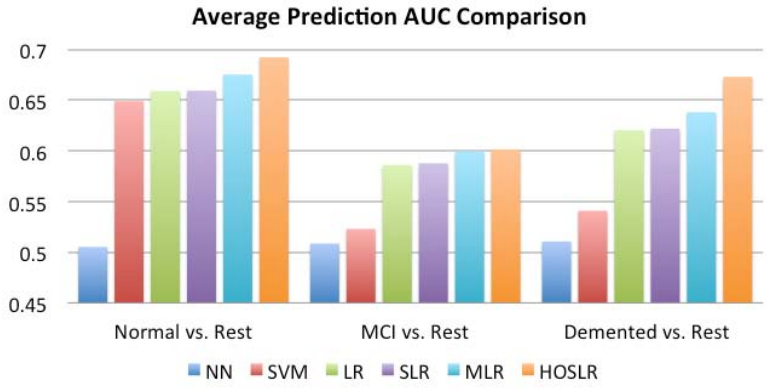

Figure 2: Average prediction AUC over 5-fold cross validation comparison for different methods.

GRAY, gray MRI images revealing the gray matter of the brain. In the raw scans, each voxel has a value from 0 to 1, where 1 indicates that the structural integrity of the axon tracts at that location is perfect, while 0 implies either there are no axon tracts or they are shot (not working). The raw scans are preprocessed (including normalization, denoising and alignment) and then restructured to 3D tensors with a size of $134 \times 102 \times 134$. Associated with each sample we have a label, which could be either *normal*, *Mild Cognitive Impairment* (MCI) or *demented*.

We constructed three binary classification problems to test the effectiveness of our *HOSLR* method, i.e., *Normal* vs. *Rest* (MCI and Demented), *MCI* vs. *Rest* (Normal and Demented), *Demented* vs. *Rest* (Normal and MCI). For *HOSLR*, because the input fMRI images are three dimensional tensors, we set the ℓ_1 term regularization parameters on all three dimensions equal, i.e., $\lambda_1 = \lambda_2 = \lambda_3$ and tune it from the grid $\{10^{-3}, 10^{-2}, 10^{-1}, 1, 10, 10^2, 10^3\}$ with five fold cross validation. The ℓ_2 term regularization parameters are set to $\mu_1 = \mu_2 = \mu_3 = 10^{-4}$. For comparison purpose, we also implemented the following baseline algorithms:

- **Nearest Neighbor** (NN). This is the one nearest neighbor classifier with standard Euclidean distance.
- **Support Vector Machine** (SVM). This is the regular vector based SVM method.
- **Logistic Regression** (LR). This is the traditional vector based logistic regression method.
- **Sparse Logistic Regression** (SLR). This is the vector based sparse logistic regression.
- **Multilinear Logistic Regression** (MLR). This is equivalent to *HOSLR* with all $\ell 1$ regularization parameters setting to 0.

We use *LIBLINEAR* [28] for the implementation of LR and SLR, and *LIBSVM* [29] for the implementation of SVM. Note that in order to test those vector based approaches, we need to stretch those fMRI tensors into very long vectors (with dimensionality 1,831,512). Fig.2 summarized the average performance over 5-fold cross validation in terms of Areas Under the receiver operating characteristics Curve (AUC) values. The data we used are the FLAIR images. From the figure we can observe that *HOSLR* beats all other competitors in all three tasks. This is because *HOSLR* can not only take into consideration the spatial correlation between three different dimensions in those fMRI images, but also exploring their joint sparsity structures (the FLAIR images are sparse in nature).

4.2 Experiments on Predicting the Onset Risk of Congestive Heart Failure Patients

Congestive heart failure (CHF), occurs when the heart is unable to pump sufficiently to maintain blood flow to meet the needs of the body, is a major chronic illness in the U.S. affecting more than five million patients. It is estimated CHF costs the nation an estimated $32 billion each year [30]. Effective prediction of the onset risk of potential CHF

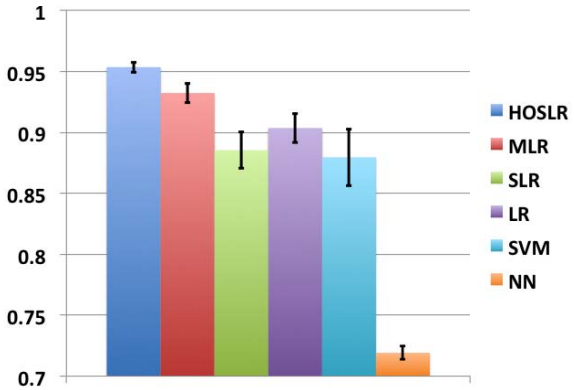

Figure 3: Prediction performance for different methods on the CHF onset prediction task in terms of averaged AUC value with 5-fold cross validation along with their standard deviations.

patients would help identify the patient at risk in time, and thus the decision makers can provide the proper treatment. This can also help save huge amount of unnecessary costs.

The data set we use in this set of experiments is from a real world Electronic Health Record (EHR) data warehouse including the longitudinal EHR of 319,650 patients over 4 years. On this data set, we identified 1,000 CHF case patients according to the diagnostic criteria in [3]. Then we obtained 2,000 group matched controls according to patient demographics, comorbidities and primary care physicians similar as in [3]. We use the medication orders of those patients within two years from their operational criteria date (for case patients, their operational criteria dates are just their CHF confirmation date; for control patients that date is just the date of their last records in the database). On each medication order we use the corresponding pharmacy class according to the United States Pharmacopeial (USP) convention[1] and the primary diagnosis in terms of Hierarchical Condition Category (HCC) codes [31] for the medication prescription. In total there are 92 unique pharmacy classes and 195 distinct HCC codes appeared in those medication orders. Therefore each patient can be represented as a 92×195 matrix, where the (i, j)-th entry indicates the frequency that the i-th drug was prescribed during the two years with the j-th diagnosis code as primary diagnosis.

The parameters for *HOSLR* are set in the same manner as the experiments in last subsection. For comparison purpose, we also implemented NN, SVM, LR, SLR, MLR and reported the averaged AUC value over 5-fold cross validation along with their standard deviations on Fig.3. From the figure we can get similar observations as we saw in Fig.2.

Another interesting thing to check is which medications and diagnosis play key roles during the decision. Because in this set of experiments we have two feature modes: medications and diagnosis, we will get two decision vectors $\mathbf{w}_{\text{med}}$ and $\mathbf{w}_{\text{diag}}$, one on each mode. The bilinear decision function in this case can be written as

$$f(\mathbf{X}) = \mathbf{w}_{\text{med}}^\top \mathbf{X} \mathbf{w}_{\text{diag}} = \mathbf{1}^\top \left((\mathbf{w}_{\text{med}} \mathbf{w}_{\text{diag}}^\top) \odot \mathbf{X} \right) \mathbf{1} \tag{10}$$

where $\mathbf{1}$ denotes all-one vector of appropriate dimension, $\odot$ is element-wise matrix product. The importance of the (i, j)-th feature X_{ij} to the decision can be evaluated as $w_{\text{med}}(i) w_{\text{diag}}(j)$. Therefore if both the magnitudes of $w_{\text{med}}(i)$ and $w_{\text{diag}}(j)$ are large, then the feature pair (medication i, diagnosis j) will definitely be important. We list in Table 1 the top diagnoses and medications according to their coefficient magnitudes in $\mathbf{w}_{\text{diag}}$ and $\mathbf{w}_{\text{med}}$. From the table we can see that the diagnoses are mainly hypertension, heart disease and some common comorbidities of heart failure including chronic lung disease (e.g., *Chronic Obstructive Pulmonary Disease* (COPD) [32]) and chronic kidney disease [33]. The top medications include drugs for treating heart disease such as Beta blockers and calcium blockers, and medicine for treating lung disease such as *Corticosteroids*. There are also medicine for treating heart failure related symptom, such as Gout, which is a well-known Framingham symptom [34]. Vaccine is also an important treatment for reducing the stress on heart [35].

5 Conclusions

We propose a high order sparse logistic regression method called *HOSLR* in this paper, which can directly take data matrices or tensors as inputs and do prediction on that. *HOSLR* is formulated as an optimization problem and we propose an effective BCD strategy to solve it. We validate the effectiveness of *HOSLR* on two real world medical scenarios on predicting the onset risk of Alzheimer's disease and heart failure. We demonstrate that *HOSLR* can not only achieve good performance, but also discover interesting predictive patterns.

Abstract

Disease risk prediction has been a central topic of medical informatics. Although various risk prediction models have been studied in the literature, the vast majority were designed to be single-task, i.e. they only consider one target disease at a time. This becomes a limitation when in practice we are dealing with two or more diseases that are related to each other in terms of sharing common comorbidities, symptoms, risk factors, etc., because single-task prediction models are not equipped to identify these associations across different tasks. In this paper we address this limitation by exploring the application of multi-task learning framework to joint disease risk prediction. Specifically, we characterize the disease relatedness by assuming that the risk predictors underlying these diseases have overlap. We develop an optimization-based formulation that can simultaneously predict the risk for all diseases and learn the shared predictors. Our model is applied to a real Electronic Health Record (EHR) database with 7,839 patients, among which 1,127 developed Congestive Heart Failure (CHF) and 477 developed Chronic Obstructive Pulmonary Disease (COPD). We demonstrate that a properly designed multi-task learning algorithm is viable for joint disease risk prediction and it can discover clinical insights that single-task models would overlook.

1 Introduction

Disease risk prediction [1] has been extensively studied in the literature. The latest trends include building risk prediction models based on a large amount of features from Electronic Health Record (EHR) databases and adopting state-of-the-art machine learning algorithms, such as Generalized Linear Regression, Support Vector Machine, Bayesian Networks, etc. [2, 3, 4]. What many existing risk prediction models have in common is that they are designed to be single-task, i.e. they only predict the risk of a single disease at a time. With a given target disease, a single-task risk model would select features that are most informative for this particular target, and then train the model using the training data set.

However, in practice we often have training data for multiple different yet related target diseases at the same time, e.g. hypertension and heart diseases, diabetes and cataract, depression and obesity, etc. In these application scenarios, single-task risk models have two significant limitations. First, by treating different target diseases separately, they fail to identify the underlying correlation between these diseases such as their common causes, similar symptoms, comorbid conditions, and distinguishing factors. These information are sometimes more important to clinical practitioners than risk prediction itself because they lead to insights on the underlying mechanisms of diseases. Second, applying a single-task model limits us to the training data that have been labeled for that particular disease, even though the training data from other related diseases can also be helpful. For instance, a single-task model will not be able to augment a small training data set labeled for heart failure with another large training data set labeled for hypertension, even though it is common knowledge that hypertension is closely related to heart failure and share many important risk predicators.

In the machine learning literature multi-task learning has been extensively studied [5, 6, 7]. However, existing multi-task learning techniques cannot be directly applied to the problem of EHR-based risk prediction because the validity of each algorithm relies on the specific assumption it makes about task relatedness and these assumptions often fail to hold for many clinical applications. For example, some models assume different tasks are close to each other as if they are derived from the same underlying distribution [7, 8], or alternatively, assume the tasks have group structure and are similar within each group [9, 10, 11]. Other models formalize task relatedness by assuming all tasks share a latent feature space [6, 5, 12]. Our proposed framework falls into this category.

In this paper we explore the viability of designing a multi-task framework for EHR-based risk prediction. In order to do this, we first need to define the relatedness between multiple diseases. In particular, we make the assumption that

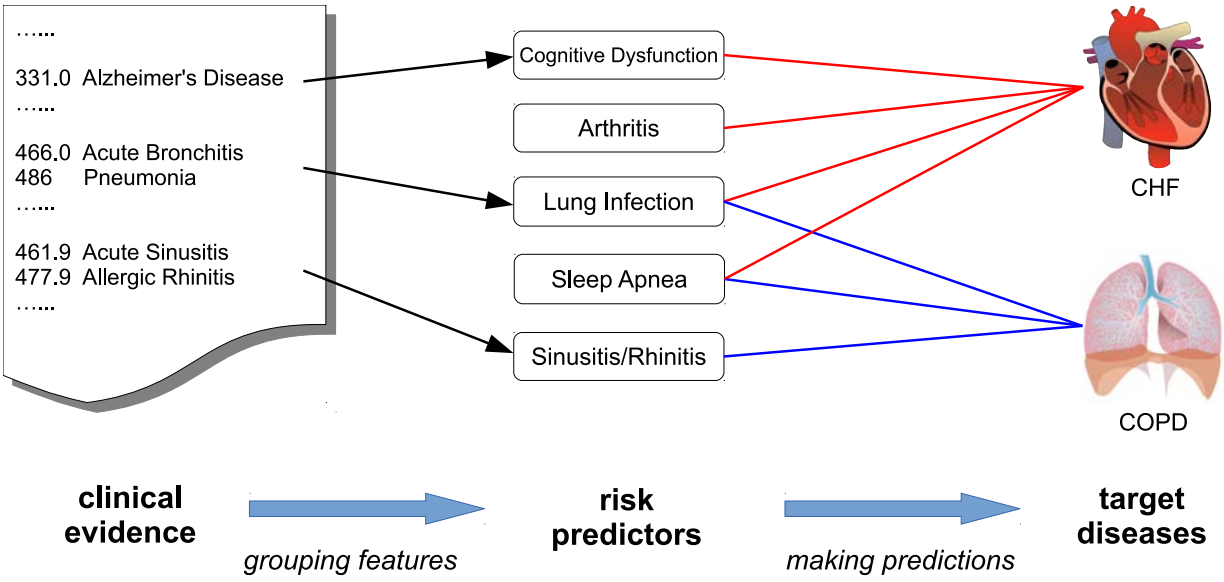

Figure 1: An intuitive example to demonstrate the problem setting for multi-task risk prediction. The lines between target diseases and risk predictors indicate strong connection. The arrows show the mapping from the raw clinical evidence (diagnosis code in this case) to the high-level risk predictors. We want to learn both the lines and the arrows.

if two (or more) diseases are related then they must share some common risk predictors and these risk predictors can be characterized by groups of the clinical evidence from the EHR database.

To intuitively understand what our assumption implies in practice, consider a group of individuals who are at risk of two diseases: Congestive Heart Failure (CHF) and Chronic Obstructive Pulmonary Disease (COPD). Traditional risk models attribute the risks directly to the raw medical features from the EHR database, such as individual diagnosis codes, lab results, vitals, etc., which are often noisy and sparse [13]. Under our framework, we attribute the risks to some higher-level latent risk predictors, which are modeled as groups of the raw medical features. As show in Figure 1, our two target diseases, CHF and COPD, share some common risk predictors such as sleep apnea, hypertension, respiratory system infection [14, 15, 16, 17]. Therefore, studying them jointly will help us more accurately pinpoint these underlying predictors and consequently facilitate the risk prediction. In addition, these two diseases also have their own risk predictors, such as Rhinitis for COPD and Arthritis for CHF. It will be beneficial to identify such predictors because they can help us better distinguish these two diseases with very similar symptoms and comorbidities [18].

Given our mild assumption, which will hold for a wide range of diseases and EHR data, our goal becomes how to jointly identify these common predictors across different diseases. To do so, we develop an optimization based formulation that simultaneously learns the feature groups and predicts the risk for all diseases based on the identified predictors. We show how to solve our objective function efficiently using an alternating minimization algorithm. To validate our proposed framework, we apply it to a real EHR database with 7,839 patients, among which 1,127 developed Congestive Heart Failure and 477 developed Chronic Obstructive Pulmonary Disease. By using diagnosis codes as underlying features, we demonstrate that our model is able to identify a meaningful set of shared risk predictors for CHF and COPD and good prediction accuracy ensues.

2 Study Design

We chose two tasks for joint prediction: CHF onset and COPD onset. CHF and COPD are well known to have significant overlap in terms of common comorbidities, risk factors, and symptoms [14, 15, 16]. In fact they are so

similar that in practice they are often misdiagnosed for each other [18]. Thus it is highly desirable if we could risk stratify them jointly and identify not only the common predictors that they share but also the unique predictors that distinguish them.

Our study is on a real-world EHR data warehouse including the records of 319,650 patients over 4 years. We identified 1,127 CHF case patients with 3,850 control match, and 477 COPD case patients with 2,385 control match. We extracted the same features for both cohorts, namely ICD-9 diagnosis codes.

2.1 CHF Cohort Construction

We defined CHF diagnosis using the following criteria (which are similar to the criteria used in [3]): (1) ICD-9 diagnosis of heart failure appeared in the EHR for two outpatient encounters, indicating consistency in clinical assessment; (2) at least one medication were prescribed with an associated ICD-9 diagnosis of heart failure. The diagnosis date was defined as the first appearance in the EHR of the heart failure diagnosis. These criteria have also been previously validated as part of Geisinger Clinical involvement in a Centers for Medicare & Medicaid Services (CMS) pay-for-performance pilot [19]. With this criteria, we extracted from the database 1,127 CHF case patients. Following the case-control match strategy in [3], a primary care patient was eligible as a control patient if they are not in the case list, and had the same PCP as the case patient. Approximately 10 eligible clinic-, sex-, and age-matched (in five-year age intervals) controls were selected for each heart failure case. In situations where 10 matches were not available, all available matches were selected. Following this strategy, we got CHF 3,850 control patients, so on average each case patient was matched with approximately 3 controls.

2.2 COPD Cohort Construction

We defined COPD diagnosis also using two criteria: (1) the occurrence of at least one COPD-related ICD-9 diagnosis code; (2) the prescription of at least one COPD-related medication. The diagnosis date was defined as the date when both criteria were met. In the end we identified 477 COPD case patients. We matched these case patients by identifying control patients were similar in age, sex, and PCP. An eligible control patient should also have a valid ICD-9 outpatient diagnosis which is not (a) a symptom code (b) a screening diagnosis, or (c) a COPD-related diagnosis. In the end we identified 2,385 control patients, which gave us a 1:5 case-control match.

2.3 Feature Extraction

For all patients we extracted their ICD-9 codes from the EHR database. We only considered the medical records that occurred from 540 days prior to the diagnosis date till 180 days prior to the diagnosis date. In other words, we used about a year worth of data to make prediction at least half a year before the disease onset. Patients who had insufficient amount of records were not included. For control patients, we set the last day of their available records as the diagnosis date and followed the same rule. In total there were 4,784 unique ICD-9 codes from all patients. After removing infrequent features, i.e. ICD-9 codes that occurred to fewer than 100 different patients (case and control combined), we had 267 distinct features left. In total 80,472 medical records were considered, which indicates our input data was extremely sparse. After features were extracted, we discarded the temporal order within the observation window and used binary encoding to record wether or not a certain feature was assigned to a certain patient during that time.

3 Model Derivation

Objective: Suppose we have T target diseases (tasks), D features from the EHR database, and N_t patients for the t-th task. For each task we have an observation matrix $X_t \in \mathbb{R}^{D\times N_t}$. The (j,i)-th entry of X_t denotes the occurrence of feature j to patient i. $\mathbf{x}_{t_i}$ is the i-th column of X_t. $\mathbf{y}_t \in \{-1,1\}^{N_t}$ is the response vector for task t: $\mathbf{y}_{t_i} = 1$ means patient i is diagnosed disease t, -1 otherwise. $U \in \{0,1\}^{D\times K}$ is a mapping from the D medical features to K groups. The rows of U sum up to one, which means each feature belongs to one group. $\mathbf{w}_t \in \mathbb{R}^K$ is the regression coefficients

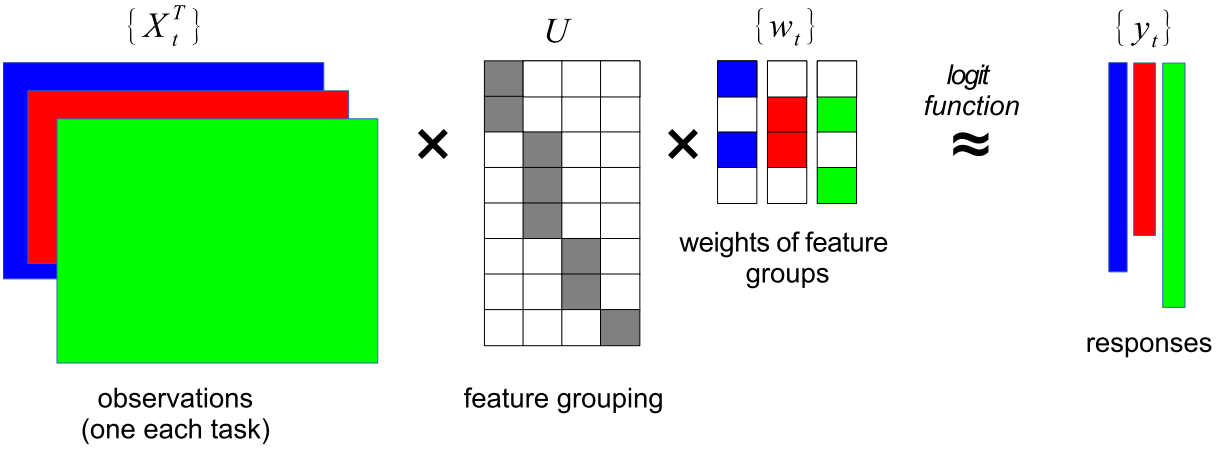

Figure 2: An illustration of our multi-task learning framework. The clinical features from the EHR database are assigned into feature groups, as defined by the assignment matrix U that is shared across all diseases. $\{X_t, \mathbf{y}_t\}$ are input and we want to learn U and $\{\mathbf{w}_t\}$. In this illustration, $D = 8, K = 4, T = 3$.

over the K feature groups for the t-th disease. A positive entry in $\mathbf{w}_t$ means that feature group contributes positively to the risk of disease t and vice versa. Figure 2 is an illustration of our framework.

Our objective is to learn the feature grouping U and the regression coefficients $\{\mathbf{w}_t\}$ simultaneously and jointly over T diseases. Formally it can be written as:

$$\underset{\{\mathbf{w}_t \in \mathbb{R}^K\}, U \in \{0,1\}^{D \times K}}{\operatorname{argmin}} \sum_{t=1}^{T} \left(\frac{1}{N_t} \sum_{i=1}^{N_t} \log(1 + \mathbf{e}^{-\mathbf{y}_{t_i} \mathbf{x}_{t_i}^T U \mathbf{w}_t}) + \lambda \|\mathbf{w}_t\|_1 \right) \quad \text{s.t.} \sum_{k=1}^{K} U_{dk} = 1, \forall d = 1, \ldots, D \tag{1}$$

where $\|\cdot\|_1$ is element-wise $\ell 1$ norm $\|A\|_1 = \sum_{i,j} |A_{ij}|$, $\lambda > 0$ is a user-specified parameter.

Interpretation: The first term inside the summation of Eq.(1) is the empirical loss. Here we choose the logistic loss, one that is mostly commonly used for clinical risk models. The second term is a regularizer that enforces sparsity on the regression coefficients $\mathbf{w}_t$. Intuitively this term wants each disease to be explained by a smaller number of groups (thus a simpler explanation). Additional regularizers can be added according to the practical needs. The constraint term in Eq.(1) says the rows of U should sum up to 1, which implies the K feature groups are a disjoint partition of the D medical features. This is to make the feature groups semantically distinct.

Eq.(1) is intractable due to the combinatorial nature of U. To overcome this, we relax the constraint on U by allowing the entries in U to take real values. After the relaxation, our objective becomes:

$$\underset{\{\mathbf{w}_t \in \mathbb{R}^K\}, U \in \{0,1\}^{D \times K}}{\operatorname{argmin}} \sum_{t=1}^{T} \left(\frac{1}{N_t} \sum_{i=1}^{N_t} \log(1 + \mathbf{e}^{-\mathbf{y}_{t_i} \mathbf{x}_{t_i}^T U \mathbf{w}_t}) + \lambda \|\mathbf{w}_t\|_1 \right) \quad \text{s.t. } U^T U = I_K \tag{2}$$

Note that the orthogonality constraint now replaces the original constraint in Eq.(1) to enforce distinction among different groups. Eq.(2) now allows an efficient solution.

Optimization: To solve the objective function in Eq.(2), we alternate between U and $\{\mathbf{w}_t\}$ by fixing one and updating the other to minimize Eq.(2) until a local optimum is reached. When U is fixed, Eq.(2) becomes:

$$\underset{\{\mathbf{w}_t \in \mathbb{R}^K\}}{\operatorname{argmin}} \sum_{t=1}^{T} \left(\frac{1}{N_t} \sum_{i=1}^{N_t} \log(1 + \mathbf{e}^{-\mathbf{y}_{t_i} \tilde{x}_{t_i}^T \mathbf{w}_t}) + \lambda \|\mathbf{w}_t\|_1 \right) \tag{3}$$

where $\tilde{x}_{t_i}^T = \mathbf{x}_{t_i}^T U$. This is a set of T standard $\ell 1$-regularized logistic regression problems [20] and can be solved independently using a variety of ready-to-use solvers.

Table 1: Feature groups identified by our model with top-5 features with highest weights ($K = 3$).

Weights	ICD-9	Description
Feature Group 1: Predictors shared by CHF and COPD ($\mathbf{w}_{CHF} = 2.176, \mathbf{w}_{COPD} = 1.390$)		
0.329	715	Osteoarthrosis and Allied Disorders
0.257	729	Disorders of Soft Tissues
0.246	724	Disorders of Back
0.229	V72	Special Investigations and Examinations
0.227	719	Cardiac Dysrhythmias
Feature Group 2: Predictors mainly associated with CHF ($\mathbf{w}_{CHF} = 1.739, \mathbf{w}_{COPD} = 0.767$)		
0.248	427	Cardiac Dysrhythmias
0.224	250	Diabetes Mellitus
0.196	414	Chronic Ischemic Heart Disease
0.120	429	Ill-Defined Descriptions of Heart Disease
0.109	411	Acute Ischemic Heart Disease
Feature Group 3: Predictors mainly associated with COPD ($\mathbf{w}_{CHF} = 0.082, \mathbf{w}_{COPD} = 5.084$)		
0.318	493	Asthma
0.171	592	Kidney Stones
0.162	388	Disorders of Ear
0.148	461	Acute Sinusitis
0.144	305	Tobacco Use Disorder

When $\{\mathbf{w}_t\}$ is fixed, Eq.(2) becomes

$$\underset{U \in \mathbb{R}^{D \times K}}{\operatorname{argmin}} \sum_{t=1}^{T} \frac{1}{N_t} \sum_{i=1}^{N_t} \log(1 + \mathbf{e}^{-\mathbf{y}_{t_i} \mathbf{x}_{t_i}^T U \mathbf{w}_t}), \text{ s.t. } U^T U = I_K \tag{4}$$

We solve this subproblem by using the Augmented Lagrange Multipliers method, which minimizes the following Lagrangian of Eq.(4):

$$F(U, \Lambda) = \sum_{t=1}^{T} \frac{1}{N_t} \sum_{i=1}^{N_t} \log(1 + \mathbf{e}^{-\mathbf{y}_{t_i} \mathbf{x}_{t_i}^T U \mathbf{w}_t}) + \text{tr}(\Lambda(U^T U - I_K)) + \frac{\rho}{2} \|U^T U - I_K\|_F^2 \tag{5}$$

where $\Lambda \in \mathbb{R}^{K \times K}$ is the Lagrange multipliers and $\rho > 0$ is a given constant.

4 Results

4.1 Identified Feature Groups

The key difference between our multi-task model and the single-task models is that our model uses feature groups instead of individual raw features as predictors. Therefore we first examine the feature groups identified from the real patient cohort for their clinical validity. An important parameter of our model is K, the number of the feature groups we want to project the raw features into. Generally speaking, K should increase with the number of tasks T to ensure enough descriptive power. Here since we only have two tasks, we set $K = 3$ for the clarity of presentation. Also for the sake of clarity, we pre-grouped ICD-9 codes into ICD-9 group codes, i.e. the first 3 digits. For each feature group we display in Table 1 the top ICD-9 group codes according to their weights, U_{ki}. A larger weight indicates this ICD-9 group code is associated more strongly with the feature group. For each feature group we also display its regression coefficients $\mathbf{w}_t$ for both tasks, from which we can tell how much this feature group as a predictor contributes to the risk of respective diseases.

The first group in Table 1 consists of ICD-9 codes that are associated with both CHF and COPD. We can see that they are mainly musculoskeletal disorders. These are common problems that can be caused either by CHF or COPD. The

second group consists of diagnosis that are mainly associated with CHF, such as heart arrhythmia, diabetes, ischemic heart diseases, and so on. These are all known risk factors for CHF. As a contrast, the third feature group shows diagnosis that are mainly associated with COPD, where we can find tobacco use, a leading risk factor for COPD, as well as asthma, a major comorbid condition for COPD.

Table 1 suggests that our model is indeed able to identify significant risk predictors across different tasks and group them based on whether they are shared by different tasks or only belongs to a specific task. However, we observe that there are still overlapping between the feature groups (e.g. 427 Cardiac Dysrhythmias in Group 1 and 2). This calls for more detailed investigation by physicians because the same ICD-9 (group) code can have different implications in different medical contexts. Therefore there is no simple "ground truth" on whether a specific feature should be associated with a specific target disease.

Note that after our relaxation from exclusive grouping to orthogonality constraint, every feature will appear not only in one feature group but in all feature groups with different weights (and the weights can be either positive or negative). Therefore, for each feature we need to consider the sum of its weights across all groups before we can interpret its overall contribution to the risk of task t.

4.2 Prediction Accuracy

Next we evaluate the performance of our approach in terms of prediction accuracy. The measurement we used was Area Under Receiver Operating Characteristic Curve (AUC) [21], which is a commonly used evaluation metric for risk prediction models. An AUC score of 1 means the prediction perfectly matches the ground truth whereas 0.5 means the prediction is no better than a random guess. We used 10-fold cross validation and report the median, the 25th, and the 75th percentiles as boxplot in Figure 3. For each fold we sampled 60% of the entire dataset for training and used the rest for validation.

We compare our approach (Multi-Risk) to two baseline methods. The first one is denoted Single-PCA. Instead of learning U jointly from all diseases, Single-PCA used a fixed U derived from the top-K principal components of all observed. Single-PCA represents the result we get in the single-task setting where the feature groupings are learned without supervision. The second baseline is denoted Single-Raw, which means U is set to be an identity matrix I_D. This is an extreme case of our framework where $K = D$ and all the raw features are used directly for logistic regression (without grouping). For all methods we used the same parameter settings for logistic regression. For Single-PCA and our model (Multi-Risk) we set $K = 3$.

From Figure 3 we observe that our model significantly outperformed Single-PCA after joint feature grouping. This is expected because the groupings are learned with supervision to maximize the discriminative power. On the other hand, the AUCs of our model and Single-Raw were comparable (no significant difference). However, we would like to point out that Single-Raw is designed to achieve the highest prediction accuracy possible without considering the potential association between different diseases, whereas our model can capture common predictors across different diseases without sacrificing prediction accuracy.

5 Discussion

This work is a first step towards multi-task clinical risk prediction. Our main purpose is to demonstrate that a properly designed multi-task learning objective can indeed capture the latent relatedness between different target diseases. It provides a principled way of identifying the common predictors and the discriminative predictors, both of which are clinically interesting. We also show that the identified feature groups can achieve the state-of-the-art prediction accuracy.

In our experiment, the two tasks shared a same training set. Namely, we have only one patient cohort and each patient was labeled for both tasks. This setting does not fully demonstrate the advantage of a multi-task risk model, which can combine disjoint patient cohorts from different tasks. For example, the CHF task can have one patient cohort labeled only for CHF from one database and the COPD task can have a different patient cohort (with different patients) labeled only for COPD. The only requirement is that these two cohorts must share the same feature space. Such augmentation

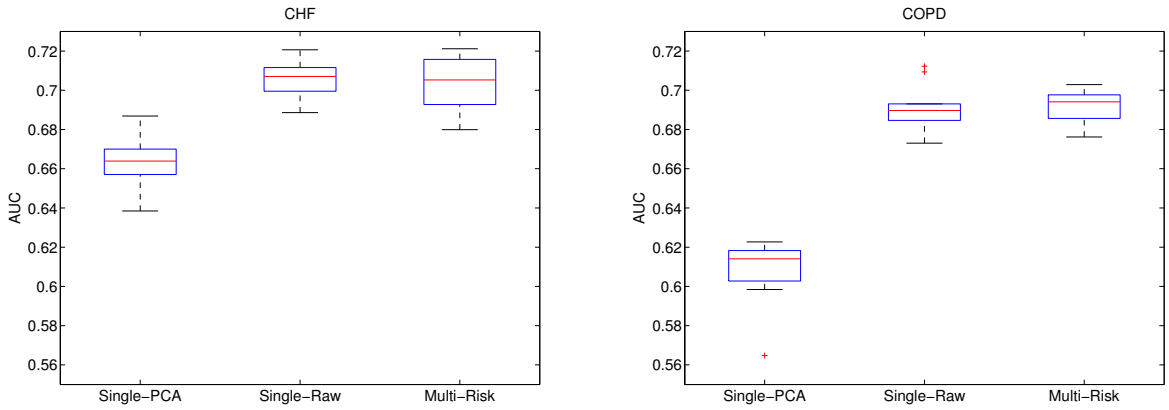

Figure 3: Accuracy of our model (Multi-Risk) for both tasks with comparison to two baseline methods. Showing the median, 25th, and 75th percentiles over 10-fold cross validation.

of the training data can potential further improve the risk prediction accuracy of our multi-task model and gives it advantage over the state-of-the-art single-task models. We leave this to future investigation.

Our multi-task learning framework can be extended in many aspects. For instance, it will be very interesting to jointly study multiple tasks from different problem domains. In our experiments, we used two similar tasks (disease onset prediction) that share the same feature set (ICD-9 codes). However, our framework can be extended to incorporate tasks from different domains, e.g. disease onset vs. hospitalization vs. need for social assistance, by grouping heterogeneous features together (diagnosis codes, medications, social behaviors, and so on). This will be a big step forward because we will be able introduce predictors from different domains for more comprehensive risk analysis.

A second direction to extend our model is to incorporate prior knowledge from domain experts. Currently our model only groups features based on how they contribute to the respective outcomes. It is not aware the clinical meaning of each feature, therefore the groups are not coherent in terms of clinical interpretation. This can be overcome if we incorporate prior knowledge into the model, which specifies the semantics of each group. For instance, domain experts can assign a few ICD-9 codes related to cardiovascular diseases to a certain group and let our model automatically identify the remaining ICD-9 codes that should also belong to the same group. Such integration can be achieved by carefully initializing U and/or introducing an additional term to regularize key entries in U.

In order to make our objective function tractable, we used the orthogonality constraint as a surrogate for exclusive group partition. The side effect of this relaxation was that U will have negative weights, which are not clinically interpretable. To overcome this, we can replace the orthogonality constraint with non-negativity constraint, i.e. $U \geq 0$. This change calls for a different optimization algorithm but produces more interpretable results.

6 Conclusion

In this work we explore a multi-task framework for joint disease risk prediction. Our framework exploits the assumption that related diseases share some common risk predictors that can be represented by groups of clinical evidence. We use the proposed model to simultaneously predict the onset risk of a CHF cohort and a COPD cohort. Preliminary results suggest that our model can identify both common and discriminative risk predictors for both diseases while pertaining good prediction accuracy. We discussed the potential of using our model to integrate patient cohorts from multiple sources and problem domains. We also discussed future improvements that can be made to enhance the interpretability of our model.

Abstract

Whole genome sequence (WGS) information could soon be routinely available to clinicians to support the personalized care of their patients. At such time, clinical decision support (CDS) integrated into the clinical workflow will likely be necessary to support genome-guided clinical care. Nevertheless, developing CDS capabilities for WGS information presents many unique challenges that need to be overcome for such approaches to be effective. In this manuscript, we describe the development of a prototype CDS system that is capable of providing genome-guided CDS at the point of care and within the clinical workflow. To demonstrate the functionality of this prototype, we implemented a clinical scenario of a hypothetical patient at high risk for Lynch Syndrome based on his genomic information. We demonstrate that this system can effectively use service-oriented architecture principles and standards-based components to deliver point of care CDS for WGS information in real-time.

Introduction

Having a patient's whole genome sequence (WGS) information available to guide clinical decision-making has been an important goal of genome research, as WGS information could be used to improve clinical diagnosis, guide preventative efforts, and inform therapeutic decisions in the clinic[1]. Indeed, several clinical examples illustrate how WGS information has been used for the clinical diagnosis and treatment of patients with rare or previously undiagnosed diseases[2–4]. A patient's WGS information available at the point of care can increase a clinician's capacity to practice personalized medicine in a routine clinical care setting[5]. In fact, as a result of the increasing availability of sequencing technology, as well as exponentially declining costs of obtaining one's genomic information, the application of WGS information to routine clinical care is becoming increasingly possible[6].

The need for clinical decision support for WGS

Although WGS information has the potential to be a valuable resource for clinical decision-making, its effective application to routine clinical care will likely be hindered by a number of challenges. Examples of such challenges include (1) static laboratory reports intended for human consumption, (2) the complexity of genetic analysis, (3) limited physician proficiency in genetics, and (4) the lack of genetics professionals in the clinical workforce[7]. Nevertheless, these challenges could be overcome by means of clinical decision support (CDS). CDS entails providing clinicians, patients, and other healthcare stakeholders with pertinent knowledge and/or person-specific information, intelligently filtered or presented at appropriate times, to enhance health and health care[8]. CDS provided within the clinical workflow, and at the point and time of decision-making within the electronic health record (EHR), has been shown to be the most effective way to deliver CDS to clinicians[9]. To realize the potential of genome-guided clinical care, CDS leveraging a patient's WGS information must be provided in real-time within the clinical workflow and the EHR[7].

Desiderata for integrating genomic information with the EHR and CDS

To address the complexity and challenges of integrating genomic information with EHRs, Masys *et al.* developed a set of desired technical requirements for EHRs to support the integration of genomic information[10]. See Table 1 for the list of these requirements.

Table 1. Desiderata for the integration of genomic data into EHRs described by Masys *et al*.

1.	Maintain separation of primary molecular observations from the clinical interpretations of those data
2.	Support lossless data compression from primary molecular observations to clinically manageable subsets
3.	Maintain linkage of molecular observations to the laboratory methods used to generate them
4.	Support compact representation of clinically actionable subsets for optimal performance
5.	Simultaneously support human-viewable formats and machine-readable formats in order to facilitate implementation of decision support rules
6.	Anticipate fundamental changes in the understanding of human molecular variation
7.	Support both individual clinical care and discovery science

Welch *et al.* developed an additional set of requirements, extending the Masys *et al.* desiderata, specifically addressing the technical requirements related to CDS for WGS information[11]. See Table 2 for a list of these requirements.

Table 2. Additional desiderata for the technical integration of WGS with CDS described by Welch *et al.*

8.	CDS knowledge must have the potential to incorporate multiple genes and clinical information.
9.	Keep CDS knowledge separate from variant classification.
10.	CDS knowledge must have the capacity to support multiple EHR platforms with various data representations with minimal modification.
11.	Support a large number of gene variants while simplifying the CDS knowledge to the extent possible.
12.	Leverage current and developing CDS and genomics infrastructure and standards.
13.	Support a CDS knowledge base deployed at and developed by multiple independent organizations.
14.	Access and transmit only the genomic information necessary for CDS.

Both of these efforts are aimed at providing guidance to system developers who are developing health IT capabilities for WGS information.

Proposed CDS architecture for WGS information

To satisfy the desiderata requirements described above, we previously proposed the use of a service-oriented architecture (SOA) to provide automatic CDS for WGS information at the point of care[12]. SOA is a software design approach which uses separate, independent software components known as services, which are self-contained components that have well-defined, understood capabilities[13]. SOA facilitates the reusability and standardization of processes, allowing for independent evolution and modifications to a particular service, reducing the burden of change on the overall system. Indeed, SOA offers many advantages to health information technology and CDS; as a result, its use is growing in health care[14]. Figure 1 shows a diagram of the SOA architecture proposed and described in further detail by Welch *et al*.[12]

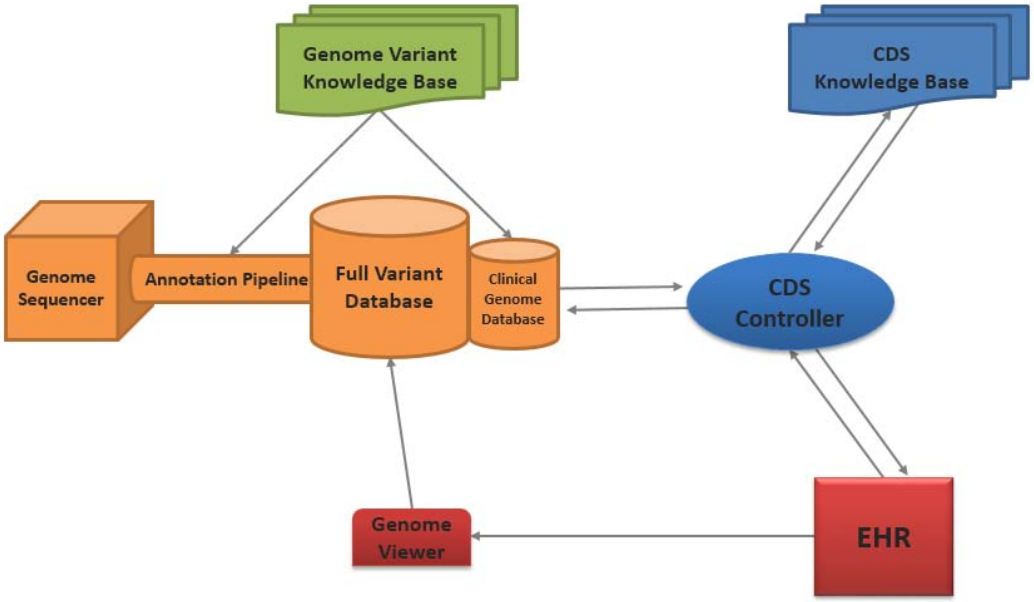

Figure 1: Overview of proposed CDS architecture for WGS information implemented as a prototype in this paper

A brief summary of each component is provided here:

- *Genome sequencing and annotation*- This component of the architecture is responsible for making the patient's genome information available and providing the genome with relevant annotations (e.g. location of variants relative to genes, impact of variants on genes, etc.). The annotation process leverages variant knowledge contained in the genome variant knowledge base.
- *Genome variant knowledge base*- This is a knowledge repository of known genome variants and assigned clinical interpretations. The primary responsibility of these knowledge repositories is to maintain the most up-to-date and accurate variant interpretations, which is important as variant interpretations are known to change over time.[15]
- *Genome database*- In the proposed architecture, a patient's genome is stored in a genome database, separate from clinical information (e.g. EHR). This database securely stores patients' genomes along with the most up-to-date variant interpretations from the genome variant knowledge base. This database also provides a standardized interface for access to a patient's genomic information.
- *CDS knowledge base*- The role of the CDS knowledge base is to process the patient-specific clinical and genomic information provided to it. It subsequently returns patient-specific, knowledge-based recommendations and/or information to support clinical care.
- *Electronic health record*- The EHR provides the patient's clinical information used by the CDS knowledge base. The EHR is also responsible for actions which trigger CDS requests and the presentation of CDS results within the clinical workflow.
- *CDS controller*- The CDS controller is responsible for processing a CDS request and assuring that all required data for CDS knowledge is available. If additional patient data is needed for CDS, the CDS controller makes a request to other data repositories (e.g. genome database) for the required information.

This manuscript describes our effort to build a functional prototype of the previously proposed CDS architecture for WGS information[12]. In this paper, we describe the open-source components and health IT standards used to develop this prototype. Furthermore, we describe the methods used to evaluate the prototype using a clinical use case involving a patient at increased risk for Lynch Syndrome. Finally, we have identified areas that will require additional research and development in the future. While others have built CDS capabilities for genomics[16–18], to our knowledge, this work is the first to describe a system that adheres to the technical desiderata[10,11] and uses a SOA approach to provide WGS-guided CDS within the clinical workflow and within the EHR.

Materials and Methods

Components used and configuration

Genome data acquisition and annotation

To obtain real WGS data used in this prototype, we used the 10Gen data set, which represents the first ten publicly available human genomes in a standardized genome variation format[19]. These genomes represent three different ethnicities (African, Asian, and Caucasian) and several sequencing platforms including SOLiD, Illumina, Sanger, Roche 454, CGenomics, and Helicos[20]. To prepare these genomes for clinical use, they were annotated using the Web-based Omicia Opal genome annotation platform.

Genome database

To persistently store a patient's annotated genomic information and make it available for CDS data requests, we implemented a relational database using MySQL Community Server (version 5.6.15) and the HeidiSQL open-source database manager[21]. In this database, we created a table named 'patient_genome' consisting of seven columns (with column names in quotes): (1) 'MRN' which is the patient's unique medical record number (MRN) that matches the patient's MRN in the Tolven open-source EHR; (2) 'gene' is the gene where the variant resides, represented using HUGO (Human Genome Organization) Gene Nomenclature Committee (HGNC) standardized nomenclature; (3) 'refSNP' is the reference SNP ID number; (4)'nuc_var' is the nucleotide variant represented in Human Genome Variation Society (HGVS) nomenclature; (5) 'pro_var' is the protein variant also represented in HGVS nomenclature; (6) 'interpretation' is the clinical impact of the variant provided by the ClinVar genome variant knowledge base; and (7) 'id' is an auto-incremented value for the primary key of the table. The 10Gen genomes were exported from Omicia as CSV files and then imported into the database through a database import process available through HeidiSQL.

To support external access to a patient's genomic data stored in the database, we developed a Web service interface deployed as a Java application within the JBoss Enterprise Application Platform version 6.1. This Web service

interface provides access to the database content using the HL7 Retrieve, Locate, and Update Service (RLUS) standard[22]. The RLUS specification can be adapted to different semantic content formats. For the present prototype, we used the HL7 Virtual Medical Record (vMR) as the semantic content format within the RLUS-based Web service.

ClinVar genome variant knowledge base

We used ClinVar as the genome variant knowledge base in this prototype. ClinVar is a publically available repository of human genome sequence variations and associated phenotypes supported by the National Center for Biotechnology Information of the U.S. National Library of Medicine[23]. ClinVar currently does not support service calls to its knowledge base, so we replicated this functionality by developing a second table in the genome database called 'genomekb' and imported a subset of ClinVar data into this table. A ClinVar full data release was downloaded directly from the ClinVar FTP site to a Linux server and transformed into a format suitable for database import using XSLT[24]. We created a SQL statement to update the interpretation field in the 'patient_genome' table from the interpretation field in the 'genomekb' table, based upon matches in the gene and variant between the two tables.

Tolven electronic health record

To store the patient's clinical information and provide a clinical workflow interface for CDS, we used the open-source Tolven electronic Clinician Health Record (eCHR™), which is provided as part of the Tolven Platform.[25] Tolven eCHR™ is an Office of the National Coordinator (ONC) certified clinical information system which supports basic clinical processes and information exchange. The Tolven Platform supports several additional components including ePrescribing, scheduling, and analytics. Tolven was selected because of (1) its open-source code; (2) its ability to be configured and customized; (3) its data model, which is based on the HL7 Reference Information Model; and (4) its use of several terminology standards such as Current Procedural Terminology (CPT), Logical Observation Identifiers Names and Codes (LOINC), and RxNorm. Furthermore, third-party plugins can be developed to extend the functionality of the Tolven Platform. We developed a plugin for Tolven using Java Enterprise Edition (version 1.6). The plugin is designed to serve three important purposes for the prototype: (1) to access the patient's clinical data stored in Tolven; (2) to create a vMR document containing the patient's data; and (3) to communicate with an external CDS Web service using the HL7 Decision Support Service (DSS) standard.

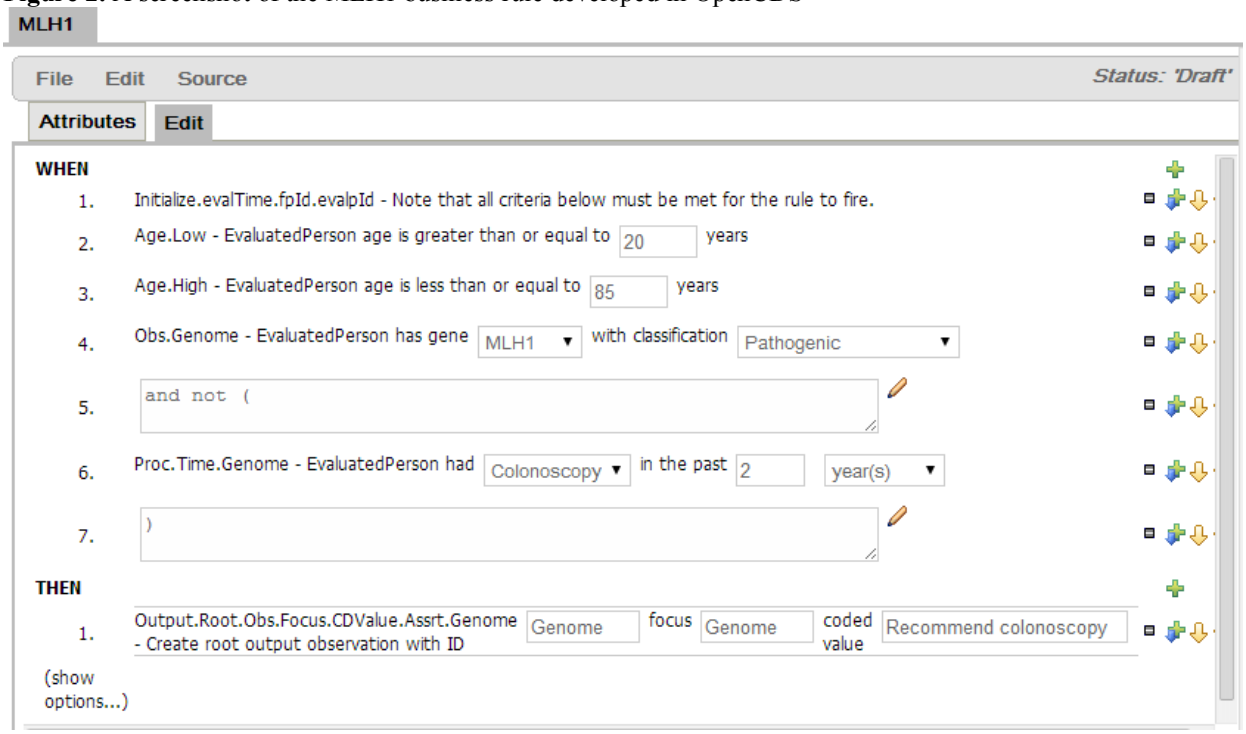
SwitchYard CDS controller

The CDS controller plays a central coordinating role in this architecture. It first processes a CDS request from Tolven and checks that all required data for CDS inferencing is available. In our prototype, it identifies that the genomic data is not available, so it makes a data request to the genome database for additional information. We used the open source solution SwitchYard (JBoss) to provide these functions. SwitchYard is a component-based SOA development framework which combines several useful components and functions for SOA into one application, including Apache Camel, Java Enterprise Edition, business process management (BPM), orchestration, routing, validation, and transformation. Within SwitchYard, we developed a composite service that includes five components: CamelServiceRoute, ProcessComponent, VerifyGenomeData, RequestGenomeData and IntegrateGenomeData. We also configured two Web service adaptors for SwitchYard to request and receive data from other components of the CDS architecture. These include (1) an adaptor for the HL7 RLUS standard to interface with the genome database Web service and (2) an adaptor for the HL7 DSS standard to interface with the Tolven EHR and OpenCDS.

OpenCDS

For the final component of the architecture, we used OpenCDS (http://www.OpenCDS.org) to serve as the CDS knowledge base. OpenCDS is an open-source, Java-based CDS framework designed to enable the delivery of CDS as a Web service compliant with the HL7 DSS standard. OpenCDS provides a knowledge authoring environment and CDS rules engine. Internally, OpenCDS uses the vMR as its data model and JBoss Drools as its inferencing engine. OpenCDS also manages and uses its own terminology within the Apelon Distributed Terminology System (DTS), with mappings created to standard terminologies such as SNOMED CT and LOINC. For this prototype, we deployed a new instance of OpenCDS and created the CDS rule logic in the Web-based knowledge authoring environment for Drools known as Guvnor. Figure 2 shows a CDS business rule authored in Guvnor and used in this prototype. After the CDS rule was created and tested in Guvnor, it was deployed within the OpenCDS run-time environment. Several vocabulary terms required by the rules were added to the OpenCDS terminology in the Apelon DTS instance used by OpenCDS.

Figure 2. A screenshot of the MLH1 business rule developed in OpenCDS



Standards Used

HL7 Decision Support Service standard

The DSS standard specifies a standard interface for providing CDS as a service and is adopted by both HL7 and the Object Management Group (OMG) standards development organizations[26]. The DSS standard includes three major interfaces including (1) *evaluation*, used to evaluate patient data and generate patient-specific results; (2) *metadata discovery*, to identify metadata and knowledge modules of a service; and (3) *query*, which is used to query for knowledge modules of interest. For this prototype, we used the evaluateAtSpecifiedTime request interface, which includes a payload section in which a base64 encoded version of the vMR is placed.

HL7 Virtual Medical Record standard

The Virtual Medical Record (vMR) is a standard HL7 clinical data model designed for CDS[27]. The vMR data model can represent patient-specific classes such as demographics, encounters, procedures, problems, medications, laboratory results, and observations. A patient's clinical data is modeled using these various vMR classes and elements. To represent the patient's genome information, we used the *ObservationResult* class. Within this class, *observationFocus* was used to represent the gene name in HGNC format, *observationValue* was used to represent the nucleotide variant in HGVS format, and *interpretation* was used to represent the variant clinical interpretation in LOINC.

HL7 Retrieve, Locate, and Update Service

The HL7 Retrieve, Locate, and Update Service (RLUS) defines the service interface to locate, retrieve, and update resources among and within healthcare organizations[22]. This specification was designed to support SOA in healthcare. The HL7 RLUS specification defines several methods including *describe*, *discard*, *get*, *initialize*, *list*, *locate*, and *put*. In our prototype, we used RLUS to request a patient's genomic information from the genome database using the *describe* and *get* methods. *Describe* returns a detailed schema definition and *get* retrieves patient data based on parameters supplied in the RLUS retrieval request.

Gene and variant nomenclature

Several genome standards were used to represent genomic information in this prototype. To represent genes, we used names approved by HGNC[28]. We used three types of standardized genome variant representations in the prototype:

(1) the refSNP number assigned to a sequence variant by dbSNP[29]; (2) the nucleotide variant in HGVS nomenclature format for coding sequence[30]; and (3) the protein variant in HGVS nomenclature for protein variation. Finally, we used LOINC to represent the possible interpretations of gene variants, which include pathogenic, presumed pathogenic, unknown significance, benign, and presumed benign[31].

The CDS process

The previous sections describe the components used in the prototype and their configurations. This section describes the overall process for providing patient-specific CDS using WGS information within the EHR. With all components of the prototype in place and functioning properly, the sequential steps of the application are as follows:

1. A patient's clinical data is recorded in Tolven by the clinician. When the patient's chart is modified and saved, a CDS request is triggered by the OpenCDS plugin in Tolven. The plugin proceeds to gather the patient's clinical data from Tolven and transform the data into the vMR format. When the patient's clinical data is all in vMR format, it is base64-encoded, placed into the DSS payload, and sent to the SwitchYard CDS controller.
2. When SwitchYard receives the DSS request with clinical data in vMR format, it validates the data against a vMR schema template defining the required data for the requested CDS knowledge module. In this case, SwitchYard identifies that the genomic data required by the CDS module is missing. It then creates a RLUS request to obtain that required information from the genome database.
3. The genome database Web service interface receives the RLUS request from SwitchYard. This interface retrieves the requested information from the genome database, which includes the gene and clinical interpretation (the return of specific variants are also available upon request). The interface creates a response RLUS message and inserts a vMR payload of the genomic information.
4. SwitchYard receives the RLUS response from the genome Web service interface and merges the genome vMR with the clinical data vMR from Tolven. If all the required data is present, a DSS request with the newly merged vMR is sent to OpenCDS.
5. OpenCDS receives the DSS request and processes the data contained in the vMR against rules in the requested knowledge module (MLH1). A CDS result is produced and sent back to SwitchYard in a DSS response.
6. SwitchYard receives the response from OpenCDS and forwards the message to Tolven.
7. When the Tolven plugin receives the response, it renders the response as an alert within the Tolven user interface, such that the CDS is provided within the clinical workflow and at the time of decision-making.

Clinical use case

To assess whether the prototype is functional, we implemented the following clinical scenario and evaluated the performance of the prototype.

Clinical use case: Lynch Syndrome risk assessment

Lynch syndrome (or hereditary nonpolyposis colorectal cancer) is an autosomal dominant genetic condition caused by pathogenic mutations in mismatch repair genes such as MSH2, MLH1, MSH6, and PMS2[32]. These mutations impact the ability of a cell to repair DNA replication errors that occur during cell division. As the cell continues to divide, these mutations continue to accumulate throughout the genome. These mutations may ultimately lead to uncontrolled cell proliferation and thus cancer. Patients who have a pathogenic variant in any of these genes possess the greatest risk for colorectal cancer, and they are also at increased risk for cancer in the stomach, intestines, liver, brain, skin and other body sites. Every year in the U.S., approximately 4,000-7,000 new cases of colorectal cancer are caused by Lynch Syndrome[32]. It is recommended that patients at increased risk for Lynch syndrome should receive a colonoscopy every one to two years starting around the age of 20 years[33]. While family history is a strong indicator for risk, genetic testing is the definitive test for a patient's Lynch Syndrome risk. Genetic screening for the disease, although currently expensive, will likely become easier when WGS information is clinically available for routine care[34]. Even then, some clinicians may not be familiar with Lynch Syndrome nor the best practices for risk mitigation and management. CDS can play an important role in the awareness and management of Lynch Syndrome.

Implementation of the clinical use case

To assess the ability of this prototype architecture to provide point-of-care CDS for Lynch Syndrome, we created and implemented the example clinical scenario found in Box 1. To implement this clinical scenario in the prototype, we created a new 32 year old patient in Tolven. For simplicity and demonstration purposes, we tested the architecture

using a single gene (MLH1) with a pathogenic variant. We assigned the publically available Venter genome to the test patient, which did not have a pathogenic mutation in the MLH1 gene[35]. Therefore, we created a known pathogenic MLH1 mutation (NG_007109.2:g.32058C>T). This genome change was created previous to a genome knowledge base update of the 'interpretation' database field in the patient_genome table. A CDS business rule representing the MLH1 recommendation for colonoscopy was created in Guvnor and deployed on the OpenCDS run time environment (see Figure 2). For simplicity, the CDS query is triggered automatically each time the patient's record is modified in Tolven.

Box 1: High-risk disease risk assessment clinical scenario

> The patient is a 32 years old male, with no personal history of colon cancer and no prior colonoscopies. The patient does not know his family health history. This patient previously had his genome sequenced, and this WGS information is available for assessment by CDS. This patient has a pathogenic mutation in the MLH1 gene, a gene associated with a high risk for Lynch Syndrome. The clinical recommendation established by his healthcare organization is to recommend that patients over 20 years old with pathogenic mutations in the MLH1 gene receive a recommendation if one has not been performed in the past 1-2 years.

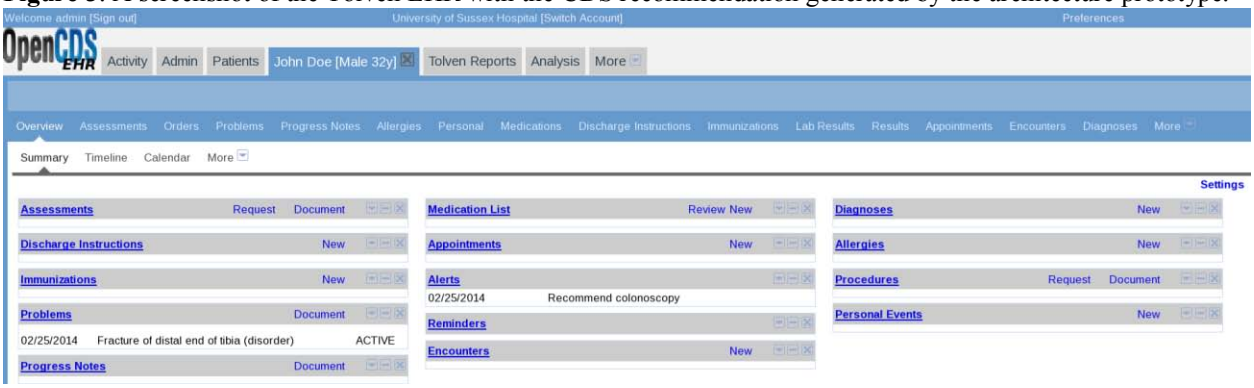
Performance evaluation

To test the performance of the architecture we used the free, open-source load testing software LoadUI (www.loadui.org) running on a Windows 7 (64-bit) machine with two processors and four gigabytes of RAM. In order to identify sources of latency, we tested each service component of the architecture separately, which included the genome application service running on a Linux Ubuntu 12.04 (64-bit) server with eight processors and 16 gigabytes of RAM, as well as the OpenCDS service running on a Linux CentOS v5.8 (64-bit) with four processors and four gigabytes of RAM. We also tested the performance of the SwitchYard CDS Controller (also running on the Linux Ubuntu server previously described) which included service calls to both the genome application and OpenCDS within its evaluation. As such, the evaluation of the CDS controller most closely represents the overall performance of the architecture. Each component was tested with a random load balance of 100 simultaneous users every 10 seconds using the same data requirements described in the clinical scenario. The overall performance evaluation was limited to 20 simultaneous users as a result of performance issues related to running Switchyard on a machine with limited processor capabilities.

Results

The objective of this study was to develop a functional prototype of our proposed architecture[12]. To that end, we implemented a prototype and verified that a patient with a clinical scenario described in Box 1 was evaluated properly by the prototype. Figure 3 shows a screenshot of the CDS recommendation successfully generated through the use of this prototype architecture within the Tolven EHR.

Figure 3. A screenshot of the Tolven EHR with the CDS recommendation generated by the architecture prototype.



Architecture performance

The genome application (which includes the service interface and database request) handled 3,109 requests over a five minute period. This genome application's fastest request took 25 milliseconds (ms), and the slowest took 697 ms, with an average of 40 ms (SD 47.44 ms). OpenCDS handled 3,015 requests over a five minute period. The fastest request took 7 ms, and the slowest took 914 ms, with an average of 12 ms (SD 17.04 ms). We also evaluated the performance of the CDS controller, which includes service calls to the genome application and OpenCDS and thus closely represents the overall performance of the architecture. Due to hardware limitations of our machine, we limited the

testing to 20 simultaneous users. The CDS controller handled 650 requests over a five-minute period. The fastest request took 356 ms the slowest took 4,243 ms, with an average of 944 ms (SD 621.04). It is important to note that the average response time was under one second. See Table 4 for a performance summary.

Table 4: Performance results of the architecture components using LoadUI

Component	Simultaneous Users	Total requests handled	Min request time (time in ms)	Max request time (time in ms)	Average request time (time in ms)	Standard deviation
Genome app	100	3109	25	697	**40**	47.77
OpenCDS	100	3015	7	914	**12**	17.04
Overall	20	650	356	4243	**944**	621.04

Discussion

As demonstrated by this prototype and demonstration, a service-oriented CDS architecture is able to support the provision of genome-guided CDS at the point of care within the EHR. Indeed, this prototype leverages standards and open-source solutions, and it is capable of integrating with current health IT architectures and workflows.

Issues identified

Throughout the process of developing the prototype of this architecture, several issues were identified. We used ClinVar as the genome variant knowledge base for this prototype because it was easily accessible and publically available. Unfortunately, ClinVar is still in a very early stage with regards to its variant knowledge base, limiting its ability to provide clinical interpretations for relevant variants. Specifically, the available variant knowledge in ClinVar is a small, but growing, subset of all available variant knowledge[36,37]. Nevertheless, it is expected that ClinVar will improve over time as more laboratories begin contributing their variant knowledge. Also, variants reported to ClinVar can range in quality on a scale from one to five stars, ranging from a single submitter's interpretation to variants reviewed and submitted by expert panels. This variable quality of variant interpretation or potential disagreement between submitters can be challenging for CDS to manage. Ideally, variant interpretations used in CDS should meet a minimum threshold of quality and confidence. A recent NIH-funded initiative called ClinGen is expected to improve the data available in ClinVar[38]. Although other genome variant knowledge bases are also available (such as the Human Genome Mutation Database), we did not integrate them with this prototype due to the time and cost associated with each integration. Integrating such variant knowledge bases into the architecture is an anticipated future effort. Nevertheless, once ClinVar becomes more developed, we believe it represents an ideal resource for genome variant knowledge management because of its public financing and its potential to become the largest single repository of genome variant knowledge[12].

Strengths and limitations

An important strength of this work is the use of freely available, open-source components. Indeed, anyone with sufficient training in the technologies used could rebuild this architecture without needing to purchase and use proprietary software or components. Another strength of the architecture is the use of available health IT standards wherever possible. Such standards and terminologies include the HL7 DSS standard, HL7 vMR standard, LOINC, HGNC, and HGVS. As a result, we were able to demonstrate that standards-based approaches could be used to deliver WGS CDS which could be leveraged to support interoperability with other health IT systems in the future.

A limitation of the study is that we only demonstrated this architecture working using a simple scenario in one clinical use case (Lynch Syndrome risk assessment). While, there are many other clinical and genomic scenarios (such as pharmacogenomics) that could be tested and demonstrated with this architecture, the scope of this effort was limited to assessing whether the proposed prototype could deliver standards-based CDS within a hypothetical clinical workflow and within the EHR. Nevertheless, we are planning to demonstrate the extensibility of the architecture with various clinical genomic use cases in future work. Another limitation of the study is that we have only integrated the CDS architecture with a single EHR using a simple CDS event trigger. While the primary aim of the current effort was to demonstrate minimum feasibility, future efforts will need to focus on integrating the architecture with other EHRs with more intuitive event triggers. Of note, the integration of SOA CDS capabilities into various EHRs is part of larger OpenCDS initiatives, outside the scope of the current research on CDS for WGS information.

Future directions

While we were able to demonstrate feasibility of this architecture using open-source solutions and standards, it took a significant amount of configuration of these components to make this possible. As a result, a future direction of this

research is to develop this CDS architecture into an easily deployable format for healthcare organizations to set up and run with minimal modification. Such a solution could potentially consist of a virtual machine image which includes a preconfigured genome database already linked to several genome variant knowledge bases, OpenCDS configured for genome rule authoring, and SwitchYard set up to support WGS-enabled CDS. Furthermore, it will be important to develop and include integration plugins for commercial EHR systems. Indeed, EHR systems are starting to support service capabilities, and future Meaningful Use guidelines may require all EHRs to support them, meaning this architecture has the potential to be used on a widespread basis for WGS CDS in the near future[39]. Likewise, as standards-based CDS integration with EHRs becomes more widespread, it will be important to test the functionality with end-users and conduct clinical trials evaluating the clinical impact of genome-guided CDS using this approach.

Another important future effort is to build the genomic CDS knowledge base and expand the current genome database. As this architecture supports a CDS knowledge base that can serve multiple health care organizations, it may be possible to develop a genomic CDS knowledge base which could be shared among these organizations. Such an effort could involve the collaboration of informaticists, geneticists, and clinical experts to implement published clinical genomics guidelines into a computable CDS knowledge representation. Furthermore, such experts could also review the literature and current clinical practices to develop new genomic CDS knowledge for clinical care. During this processes of developing a genomic CDS knowledge base, additional data requirements for inclusion in the genome database will likely be identified. For example, in the current version of the genome database, only genes and variants are included. While these data may be sufficient for Lynch Syndrome and other autosomal dominant use cases, these data would not be sufficient for autosomal recessive genetic conditions and other types of genomic use cases (e.g. SNP-based testing). As a result, it will be necessary to add additional genomic information for CDS, such as chromosome number, zygosity, tandem repeat number, or sequencing quality scores. These additional genomic data requirements could potentially be identified though a systematic review of the literature and the involvement of various domain experts.

Conclusion

Using WGS information in the clinic for routine clinical care may be challenging for clinicians to manage without assistance. CDS provided within the clinical workflow, at the time of decision-making, provides a feasible solution to enable genetically-guided personalized medicine. To evaluate this potential solution, we developed and tested a functional CDS architecture for WGS information using SOA design principles. Through this effort, we were able to demonstrate that a functional prototype of this approach is capable of providing genome-guided CDS within a hypothetical clinical workflow and within the EHR. While future research and development is necessary before such an approach can be used in a clinical setting, this study demonstrates that the approach is feasible and valid. We therefore speculate that this work will help guide future research and development on the use of WGS-based CDS to support personalized healthcare.

Stochastic Gradient Descent and the Prediction of MeSH for PubMed Records

W. John Wilbur MD, PhD and Won Kim PhD
National Center for Biotechnology Information, National Library of Medicine, National Institutes of Health, Bethesda, MD, U.S.A.

Abstract

Stochastic Gradient Descent (SGD) has gained popularity for solving large scale supervised machine learning problems. It provides a rapid method for minimizing a number of loss functions and is applicable to Support Vector Machine (SVM) and Logistic optimizations. However SGD does not provide a convenient stopping criterion. Generally an optimal number of iterations over the data may be determined using held out data. Here we compare stopping predictions based on held out data with simply stopping at a fixed number of iterations and show that the latter works as well as the former for a number of commonly studied text classification problems. In particular fixed stopping works well for MeSH® predictions on PubMed® records. We also surveyed the published algorithms for SVM learning on large data sets, and chose three for comparison: PROBE, SVMperf, and Liblinear and compared them with SGD with a fixed number of iterations. We find SGD with a fixed number of iterations performs as well as these alternative methods and is much faster to compute. As an application we made SGD-SVM predictions for all MeSH terms and used the Pool Adjacent Violators (PAV) algorithm to convert these predictions to probabilities. Such probabilistic predictions lead to ranked MeSH term predictions superior to previously published results on two test sets.

Introduction

The National Library of Medicine (NLM) produces the PubMed database of biomedical journal article citation records consisting of title, abstract (where available) and appropriate metadata. This data base currently contains over 23 million records and is growing at about 60,000 records per month. Most of these records have approximately a dozen key terms assigned to them from a controlled vocabulary known as Medical Subject Headings (MeSH). There are over 27,000 MeSH terms from which these key terms or index terms are assigned by humans. This involves significant human effort and expense. It is then natural that efforts would be made to mechanize some of this work. Such efforts have been of two types. First, there has been an ongoing effort to develop a system called the Medical Text Indexer (MTI) to predict MeSH assignments as suggestions for MeSH indexers at the NLM[1-9]. Second, there have been a number of investigations of machine learning methods and how they might be applied to the MeSH indexing problem in a more abstract setting with the purpose of understanding and comparing different approaches to this problem[6, 10-15]. The work we report here is of this latter type. We examine the Stochastic Gradient Descent (SGD) method for solving Support Vector Machines (SVMs)[16, 17] and develop an approach which we believe has broad applicability but is especially attractive for solving very large SVM problems. We show how to use this approach to improve MeSH suggestions over prior published work.

SGD has proved to be a very effective method of training machine learning algorithms[16, 17]. It has generally been found to confer a significant decrease in training time without sacrificing accuracy[17-19]. SGD can be applied to standard convex loss functions with regularization terms with good effect, but Zhang[17] suggested using SGD without the usual regularization term and performing the regularization with early stopping. This has become a widely practiced approach[20-22] and is implemented by dividing the training set into disjoint pieces consisting of a new training set and a validation set. Then on each training pass through the new training set one tests on the validation set and that number of iterations over the training data which is found to be optimal is recorded. One then trains on the original training set with this number of iterations and evaluates the results on the test set to rate the method. One of our contributions in this work is to show that on a number of text classification problems one can implement early stopping by just using a constant number of iterations and obtain the same performance as one obtains using the validation set approach.

In particular we find that SGD with a fixed number of eight iterations over the training data provides MeSH classification results as good as early stopping based on held out data and as good as several other popular methods which take much longer to train. Given the efficiency of the method we are able to apply it to each MeSH heading to make predictions. It would then be possible to use the SVM scores of all the MeSH terms for a given document to

rank the predictions for that document. However, different MeSH terms have different frequencies in the training data and this leads to classifier scores that are not directly comparable, i.e., one does not obtain the best result with such a ranking approach based on raw scores. This leads us to take a slightly different approach. We first divide the training data into two equal halves. For a given MeSH term we train a classifier on each half. We then apply the Pool Adjacent Violators (PAV) algorithm[23-26] to each classifier's scoring of the half of the training data on which it was not trained. The PAV algorithm converts raw scores to probabilities. As a consequence, for any previously unseen test document, we can apply the classifiers to obtain two raw scores and use the PAV models to convert these raw scores to probabilities. We average the two probabilities to obtain a single probability estimate for that MeSH term for the test document. Since probabilities are optimally comparable we use the resulting probabilities over all MeSH terms to make ranked MeSH term predictions. We find such predictions superior to predictions obtained by raw score ranking and also superior to previous published predictions.

Methods

The SGD Algorithm with Early Stopping Assume we are given N training points $\{(x_i, y_i)\}_{i=1}^{N}$ randomly and independently sampled from the same source distribution, where for each i, $x_i \in R^n$ and $y_i \in \{-1,1\}$. The objective is to learn a weight vector $w \in R^n$ so that the function

$$f_w(x) = \text{sgn}(w \cdot x) \tag{1}$$

has a high probability of agreeing with y if (x, y) is randomly sampled from the same source as the training data. Here the function sgn is known as the sign function and has the definition

$$\text{sgn}(x) = \begin{cases} 1, & x > 0 \\ 0, & x = 0 \\ -1, & x < 0 \end{cases}. \tag{2}$$

Then pseudocode for the SGD algorithm without regularization, but with early stopping is as follows.

SGD without regularization

Input: training data $\{(x_i, y_i)\}_{i=1}^{N}$; learning rate $\lambda > 0$.

Initialize: $w_0 = 0$; $t = 0$.

A. Randomly sample j, $1 \le j \le N$

B. If $y_j(w_t \cdot x_j) < 1$ set $w_{t+1} = w_t + \lambda y_j x_j$ and $t = t + 1$.

C. if stopping criterion satisfied return w_t else return to A.

Several issues require comment here. First, we do not deal with a threshold independent of the vectors x_i but assume that all vectors have a common added dimension which is also present in w and functions as threshold. Second, we do not randomly sample integers from the interval $[1, N]$ as in step A of the algorithm. Instead we do the training in rounds or passes over the training data and before each pass we re-randomize the order in which the integers in $[1, N]$ are visited. Third, we use a learning rate $\lambda = 0.002$. On all three of these points we are simply following[17]. Our pseudocode does not define the stopping criterion. Generally cross validation or held out data is used to determine a stopping point, but our purpose is to compare that approach to simply stopping at a fixed number of passes over the data without doing any cross validation.

Method of SGD Experiments By holding out training data, we may experimentally determine the optimal number of iterations of SGD for SVM with early stopping (L1 loss Minimization without regularization, hereafter we call it SGD-SVM)[20-22]. Let $D = \{(x_n, y_n), n = 1, \cdots, N\}$ be our data set, where x_n is a vector representing the

attributes of the nth instance and y_n is the binary class value of x_n. We randomly split the data into J equal parts $D_1, D_2 \cdots D_J$. Let D_j and $D^{(-j)} = D - D_j$ be the test and training sets for the jth fold of a J fold cross validation. For the jth fold we again randomly split the training set $D^{(-j)}$ into K equal parts $D_1^{(-j)} \cdots D_K^{(-j)}$. Defining $D_K^{(-j)}$ to be the held out or validation set, we may determine the optimal number of iterations of SVM-SGD. We train SGD-SVM on $D^{(-j)} - D_K^{(-j)}$ and let $Iter_j$ be the optimal iteration number for SGD-SVM evaluated on $D_K^{(-j)}$. We then apply SVM-SGD learning with $Iter_j$ iterations on $D^{(-j)}$, and measure the success of this learning on D^j. Note that random splits are done in such a way as to keep the number of negative records and the number of positive records the same or as close to the same as possible over all splits. The J different test results from the J different folds are combined by macro-averaging , which we believe is appropriate when all J experiments are very similar. We report mean average precision (MAP) and break even (BE) values[27] and macro-averaging means we compute the measure for each fold and then take a simple average over all folds for the final value reported. The break even value is sometimes also known as R-precision[27].

When we do the experiment without using held out data the protocol is simpler. As before, we randomly split the data into J equal parts $D_1, D_2 \cdots D_J$ and let D_j and $D^{(-j)} = D - D_j$ be the test and training sets for the jth fold of a J fold cross validation. But now $Iter_j$ is a fixed number for all j. One may ask how do we decide what this number should be. Our answer is empirical. We have observed what works well on the data from much experience based on cross validations and other experiments where we simply run the learning algorithm for a number of iterations and watch the performance. Our conclusions are surprisingly simple. For all the MeSH experiments we use 8 iterations and for all the other classification problems we study in this work we find 9 iterations give good results. We suspect this difference is due to the much larger size of the training data for MeSH than for any of the other problems we study.

Data Sets In addition to studying classification for MeSH assignment, we also study six smaller textual databases, each of which is associated with one or more classification problems. The databases and their sizes are listed in Table 1. Other than the PubMed database these sources were prepared previously by the authors and documented in[28] and to save space we refer the reader to this source for details. The PubMed database used is a March 2013 copy.

Table 1. Corpora used in this study. Given for each corpus is the number of defined sub-problems, the number of examples, and the number of features.

Database	classes	Examples	Features
REBASE	2	102,997	2,032,075

Reuters	10	27,578	46,623
PubMed	27	22,411,501	77,040,540

PubMed We study a March 2013 version of the PubMed database. As noted above, there are over 23 million records in PubMed representing as many journal articles mostly on diverse biomedical topics. More detail can be obtained online[29]. Each record in the database is represented by features consisting of the words and two word colocations contained in the title and abstract. A stoplist of function words are not allowed in these features, but no stemming is done. We divide this corpus into two thirds for training (14,941,100) and one third for testing (7,470,501). Most records in PubMed are manually assigned one or more MeSH headings. There are over 27 thousand terms in the MeSH vocabulary, giving rise to as many possible classification problems on this corpus. In a previous work[14], we studied 20 MeSH terms representing a range of frequencies. Each of these MeSH terms is listed

in Table 2 along with its frequency in the studied version of PubMed. Also shown in Table 2 are seven additional higher frequency MeSH terms that were selected for algorithm timing.

Table 2. MeSH terms used in this study of SGD-SVM on the PubMed corpus. Given for each MeSH term is the number of records indexed with that MeSH term and the percent this is of the total.

Results

SGD-SVM Experiments Three folds were used in all cross-validation experiments so that we set $J = 3$ and, where used, $K = 3$. Cross validation was used for all databases except WebKB and 20 Newsgroups which are already partitioned into training and test sets. In these latter two cases we still did the learning with an optimal number of iterations based on holding out a third of the training set to determine it versus doing the learning based on a fixed number of nine iterations over the training data.

Table 3. Results on small corpora for SGD-SVM with cross-validation and SGD-SVM with a fixed 9 iterations. Each row in the table contains the averages over all classification problems defined in that corpus. The last row averages over the corpora.

Set	SVM-SGD Cross Validation			SVM-SGD with Fixed 9 iterations

The results in Table 3 and Table 4 strongly support our contention that a fixed number of iterations gives as good performance for SGD-SVM as using held out data to determine an optimal number of iterations. We also compared SGD-SVM with three published SVM algorithms designed to work well on large training sets. These algorithms are PROBE[30], SVMPerf[31] and LibLinear[32]. Results for all algorithms are in Table 5. No single algorithm is superior to the others on all MeSH terms and SGD-SVM with a fixed 8 iterations is competitive with the others.

Table 5. Results on the PubMed corpus for the four algorithms: SGD-SVM with a fixed 8 iterations, PROBE, SVMperf and LibLinear. For each of the MeSH terms the MAP and BE are reported for a three-fold cross validation and the same folds were used for all the algorithms. The last row averages over the twenty MeSH terms.

In doing the computations for Table 5 it became evident that SGD-SVM was much faster than the other algorithms. To investigate the issue of computation time further we chose seven additional MeSH terms with high frequencies (thus large positive sets) where the calculation is more difficult. Statistics on these MeSH terms are listed in Table 2. Both performance and elapsed time (wall clock) are shown in Table 6. Two things stand out in Table 6. First, SGD-SVM performs better than PROBE or SVMPerf on these problems and at least as good as LibLinear. Second, PROBE averages between 4 and 5 hours, LibLinear between 8 and 9 hours and SVMPerf may take much longer (we stopped any calculation over 30 hours) for these problems. This in contrast with SGD-SVM which takes 10 minutes or less. We conclude from these experiments that in all circumstances, particularly for large training sets with positive sets of significantly large size, the SGD-SVM algorithm with a fixed 8 iterations is the preferred method.

Table 6. BE performance and elapsed time for classification of high frequency MeSH terms. Here SGD-SVM is with a fixed 8 iterations. All timings were conducted using a standalone multi-core computer with Intel Xeon CPUs with a clock speed of 2.67 GHz and 48 gigabytes of RAM. NA=not available.

Application to MeSH Assignment Given the speed and accuracy of SGD-SVM, we were led to contemplate calculations which would have been unthinkable in the past. There are over 27 thousand MeSH terms, but it is not difficult to train classifiers for all of them. The question is whether such a set of classifiers will yield superior performance in predicting MeSH assignments for unseen documents. To answer this question we decided to perform an experiment. There are two sets of PubMed documents on which experiments have been done in the past and with which we can compare our results. One set is known as NLM2007, is available at[33] and consists of 200 PubMed records originally selected in 1999 and used as a bench mark by several studies[2, 34, 35]. The second set is L1000, a set of 1,000 randomly selected PubMed records, created and studied in[34] and available at[36].

Based on these considerations we held out the two test sets and used the remainder of the March 2013 MEDLINE as training data. For each MeSH term we randomly divided the training set into two disjoint sets with each half having, as nearly as possible, the same number of documents with the MeSH term assigned and without the MeSH term assigned. We then trained one SGD-SVM classifier on each half. Once a classifier was trained we applied it to produce scores on the half of the documents where it had not been trained. Finally, we applied the Pool Adjacent Violators (PAV) algorithm to these scores to convert them to probabilities. This algorithm produces a probability function of scores that is non-decreasing as a function of score and gives a best fit to the actual data. Best fit here means if the probabilities are looked at as predictions of whether the MeSH term is assigned to a document or not, then the actual assignments observed in the data have maximum probability. No other non-decreasing probability function of score could assign a higher probability to the data. Since we have two trainings, one on each half of the training data, we have two probability functions. We then score the test documents for each training and convert each into a probability based on its PAV function and average these two probabilities to obtain our probability estimate that the MeSH term will be assigned to the test document. Space does not allow more detail regarding PAV, but we refer the reader to[25].

Evaluation. We give four measures of performance: precision, recall, F_1-score, and mean average precision (MAP) which evaluate success in automatic MeSH term assignment to MEDLINE citations. We use these metrics because they have been used for the same task in previous studies. These metrics are standards in the field and are described in[27]. For a given test document precision at rank 25 is the fraction of MeSH terms in the top ranked 25 which were assigned to that document by the human indexers and recall at rank 25 is the fraction of MeSH terms assigned by human indexers to that document which appear in the top 25 ranks of the prediction. The F_1-score at rank 25 is the harmonic mean of the precision and recall at rank 25. The average precision of a ranking for a document is the average of all precisions computed at ranks containing a correctly assigned MeSH term for that document. Finally, for a given set of test documents we compute these four measures for each document and average the results for each measure over all documents in the set and report this average. For average precisions this final average has been given the name of mean average precision or MAP.

We compare our approach to five other methods which were previously published in[34]. The first one is NLM's MTI system[2]. The second method is known as reflective random indexing[35]. The third and fourth are k-nearest neighbor methods. For these methods the neighbors are computed using the algorithm reported in[37]. The value of k determined to be optimal for both frequency and similarity approaches was studied in[34] and found to be 20. The fifth method is based upon a learning-to-rank algorithm which begins with the features used for ranking in the k-nearest neighbor methods and adds a number of other features and learns a weighting for these features that allows an improved ranking of the MeSH terms assigned to the k-nearest neighbors for all training documents at once. For more details see[34]. Table 7 and Table 8 list the results for the databases NLM2007 and L1000, respectively.

Table 7. Precision, recall, F-score over top 25 predictions, and MAP for different methods on the set NLP2007.

	Prec	Recall	F-Score	MAP
MTI	0.318	0.574	0.409	0.450
Reflective random indexing	0.372	0.575	0.451	N/A
Neighborhood frequency	0.369	0.674	0.476	0.598
Neighborhood familiarly	0.376	0.677	0.483	0.604
Learning-to-rank algorithm	0.390	0.712	0.504	0.626
SGD-SVM	0.390	0.712	0.504	0.640
SGD-SVM with PAV	0.405	0.740	0.524	0.681

Table 8. Precision, recall, F1-score over top 25 predictions, and MAP for different methods on the L1000 set.

	Prec	Recall	F-Score	MAP
MTI	0.302	0.583	0.398	0.462
Neighborhood frequency	0.329	0.679	0.443	0.584
Neighborhood similarity	0.333	0.687	0.449	0.591
Learning-to-rank algorithm	0.347	0.714	0.469	0.615
SGD-SVM	0.346	0.712	0.465	0.638
SGD-SVM with PAV	0.368	0.756	0.495	0.676

In these tables all results compared with SGD-SVM are taken from[34]. Two things need to be noted regarding these comparisons. First, for both NLM2007 and L1000 we used the PubMed IDs to find the current forms of the documents and our results are based on the current indexing of these documents. This is the only reasonable thing to do as our training data is all based on the current indexing. This current indexing could conceivably involve some changes that could affect the difficulty in assigning MeSH terms to a document. Since we produced the k-nearest neighbor results used in[34] and quoted in these tables, we recomputed these numbers as a check on any such possible change. We found the four measures to be identical to the numbers given here for the neighborhood frequency method for both NM2007 and L1000. For the neighborhood similarity method we found small variations. For NLM2007 the current F1-score is 0.480 (down 0.003) and the current MAP is 0.605 (up 0.001) and for L1000 the current F1-score is 0.449 (unchanged) and the current MAP is 0.592 (up 0.001). We present these results as evidence that the indexing task for NLM2007 and L1000, as they appear in the 2013 data used for this study, is substantially what it was when studied in[34] and in any case has not gotten easier. The second point we wish to make is that previous studies were limited to rankings of MeSH terms coming from a short list of neighbor documents (generally the top 20) and this limited the number of participants in the ranking to compute the MAP values reported in the tables. In our approach all MeSH are ranked for each document and this allows for a slight improvement in the MAP numbers.

We applied statistical tests to compare the MAP values produced by SGD-SVM with PAV with the Learning-to-rank results. Each method gives a figure for the average precision of MeSH assignment to a document. These pairs over all the documents in a set are then tested. The test methods and the corresponding p-values are given in Table 9.

Table 9. Comparison of SGD-SVM with PAV with Learning-to-rank. We applied the sign test, the Wilcoxon signed rank test, and the paired t test.

	NLM 2007	L1000
Sign test	1.2×10^{-9}	1.4×10^{-39}
Wilcoxon	6.0×10^{-12}	7.9×10^{-59}
Paired t test	2.5×10^{-4}	$<10^{-4}$

Discussion

From a theoretical point of view it is interesting to ask why SGD with early stopping works. In this regard it is useful to point out that what Zhang[17] calls SGD with early stopping is called by Collobert and Bengio[38] the margin perceptron algorithm. The latter authors point out that the wider the margin the better the performance is likely to be and that the margin is preserved by a small value of λ and by a small number of iterations. The small number of iterations is achieved by early stopping. However, as far as we can discern, it has not previously been appreciated that early stopping can be achieved with a fixed number of iterations for a whole class of problems.

The practical consequence of SGD with early stopping at a fixed number of passes over the data is an approximate halving of the training time. The first run with held out data to determine the optimal number of passes over the data proves unnecessary as documented in Table 3 and Table 4. SGD with early stopping is already a very useful approach on problems with large training data and using fixed iterations only adds to the benefit. With this approach there is no need to reduce the size of the training set to make the calculations feasible as done in[39]. We

used unigram and bigram features based on our own experience that this gives good performance[28]. We see that[39] also used unigram and bigram features, but due to our much larger training set sizes we had to deal with a much larger feature set (over 70 million features as compared with their approximately 2 million). In spite of this we can perform a single training run in 10 minutes and perform training over all MeSH terms in a couple of days on our compute farm using approximately 200 cpu's. While at this point we have not been able to directly compare our approach to that of[39], given that they use the same feature types and use a standard SVM approach, we would expect the two methods to perform at a similar level. The results of Table 5 and Table 6 support this conclusion.

We tested our approach on the test sets NLM2007 and L1000 because there are published results for several different methods on these sets[34] and because the particular method of testing on the top 25 predicted MeSH terms is very relevant to the MTI system at NLM. The suggestions to the MeSH indexers by the MTI system[6] are generally on the order of the top 25 terms. The precision, recall and F1 scores given in Table 7 and Table 8 are all computed for the top 25 predicted MeSH terms.

Conclusions

First, SGD with early stopping at a fixed number of iterations is an accurate and fast way to train a SVM classifier for large training sets. Second, when SGD-SVM is combined with the PAV algorithm the results on two previously studied test sets are superior to published results. We are currently collaborating with James Mork and Alan Aronson at the NLM testing whether results from SGD-SVM can be used to improve the MTI system.

Using String Metrics to Identify Patient Journeys through Care Pathways

Richard Williams, BA[1,2], Iain E. Buchan, MD, FACMI[1,2], Mattia Prosperi, M.Eng., Ph.D[1], John Ainsworth, BSc, MSc[1,2]

Abstract

Given a computerized representation of a care pathway and an electronic record of a patient's clinical journey, with potential omissions, insertions, discontinuities and reordering, we show that we can accurately match the journey to a particular route through the pathway by converting the problem into a string matching one. We discover that normalized string metrics lead to more unique pathway matches than non-normalized string metrics and should therefore be given preference when using these techniques.

Introduction

When faced with a patient's electronic health record (EHR) and a prescribed care pathway it is useful to know if that patient's care has deviated from the expected route through the pathway[1]. The degree of deviation from a pathway calculated with a distance metric, when combined with outcome data, could lead to the discovery of instances where the standard of care has been suboptimal leading to adverse outcomes, and also to instances of localized practice that lead to better outcomes.

However, before determining distance from a given route, we need accurately to determine which route through the pathway was traversed by the patient. This is a problem because routinely collected patient information is often poorly recorded with missing data, incorrect coding practice and data recorded out of sequence.

String metrics provide the distance between two strings and are usually based on algorithms for matching strings to patterns, with various degrees of approximation. They typically involve performing operations such as insertion, deletion and substitution. The string metric can be normalized[2,3] or non-normalized[4–6].

We attempt to discover the routes patients took through a care pathway by using string matching methods in a novel way with electronic health records from Salford, UK.

Related Work

Representing a care pathway in a format that can be readily interpreted by a computer is essential for analysis and also enables health information systems to provide decision support to health care professionals[7]. Computer-interpretable guidelines (CIGs) are computer representations of the clinical knowledge in a clinical guideline and are usually networks of tasks that occur over time[8]. A recent review of CIGs shows there is ongoing work on CIG modelling languages, their integration with EHRs, validation and verification of CIGs, compliance monitoring and sharing[9]. Most CIG modelling is based on Task-Network Models[8,9] of which our graph-based approach is a general case.

There is also a large body of work on process mining[10,11], frequent pattern mining, and the use of hidden Markov models for trajectory clustering[12] for healthcare data, which has been reviewed by Lakshmanan et al.[13] However, each of these techniques begin with the healthcare data and attempts to interpolate the pathways taken, whereas our approach differs by starting with a well-defined care pathway and attempts to discover the route taken.

Background

Care Pathways

Care pathways are structured guidelines for the assessment, diagnosis, and treatment of patients with a given condition[1,14–16]. They provide the ideal care that a patient should receive and are often represented as a flow chart[1,14]. In the UK, "NICE Pathways" (National Institute for Health and Care Excellence) offers pathways for over 150 conditions[17].

More formally, a care pathway flow chart can be represented as a directed graph, $G = (V, E)$, with V a set of nodes that represent clinical events such as diagnoses, measurements, procedures and treatments, and E a set of directed

edges that correspond to the permitted transitions between nodes. A transition can occur in a determined amount of time. Figure 1 shows an example of a care pathway represented as a directed graph, defined a priori by experts.

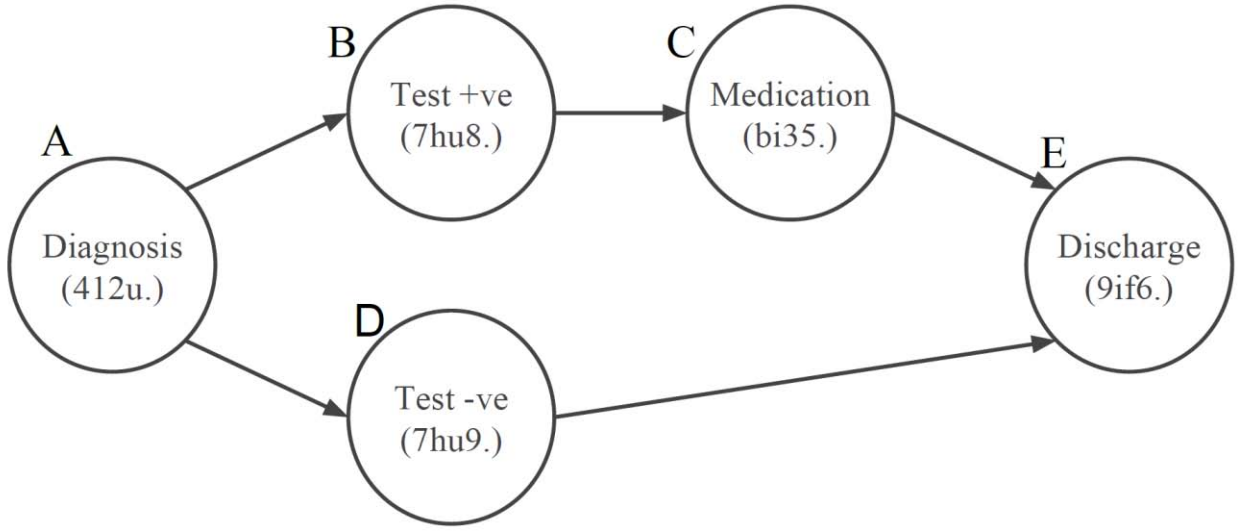

Figure 1: A graphical model of a simplified, coded care pathway. Clinical codes in parentheses.

SINAP

The Stroke Improvement National Audit Programme (SINAP)[18] is a data collection process for the purposes of clinical audit. It collects data about the care provided to stroke patients and includes several index events and the times they occurred. Here we examine data from Salford Royal Foundation Trust (SRFT) on 1078 patients with suspected strokes between 2010 and 2011. Figure 2 shows the approximate pathways that can be followed when a patient is admitted to hospital with a suspected stroke, covering the events recorded in the SINAP dataset. This is a simple pathway with only two decision points following when the patient is first seen and also after the patient has undergone brain imaging. The alphanumeric characters associated with each node in the pathway will be used later.

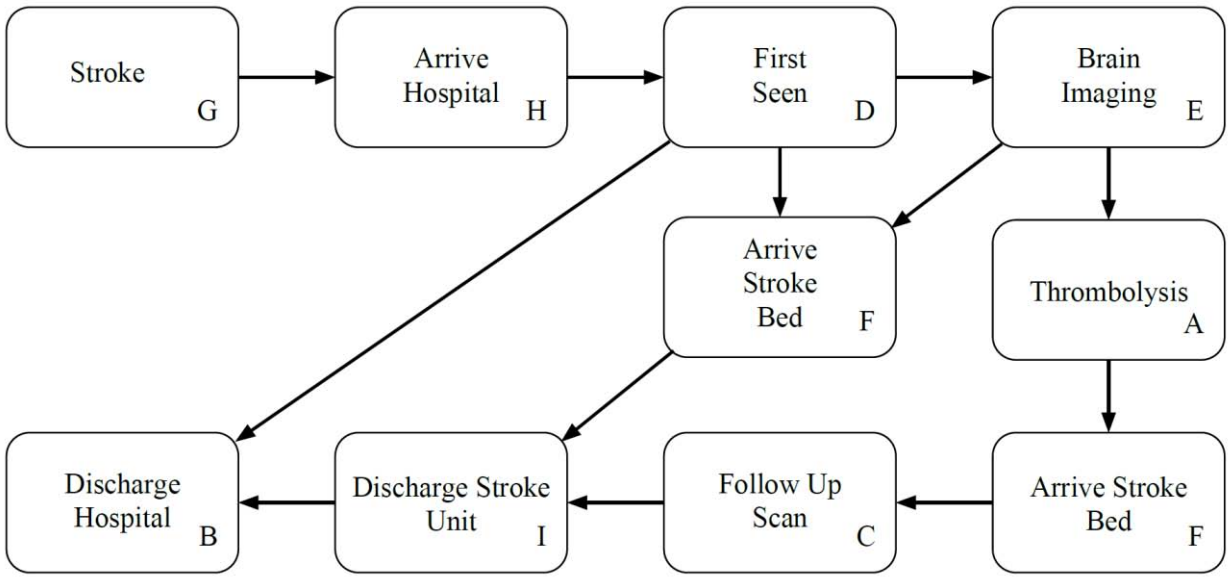

Figure 2: Stroke Improvement National Audit Programme (SINAP) pathway nodes as characters.

Electronic Health Record

A patient's EHR is typically a list of coded events and states describing their care. In the UK a variety of coding schemes are used, such as Read Codes v2[19], CTV3[19], ICD-10[20] and SNOMED[21]. The processes described in this paper can be used with any coding system: here we use the SINAP dataset that employs custom codes.

Method

Process

We first assign an alphanumeric character to each node in the graph. By using the Unicode[22] character set we can manage care pathways with up to 65,536 nodes. We then extract every possible route through the pathway as a string made up of the characters assigned to each node. For a graph G with n possible routes we construct the set $R = \{R_1, R_2, \cdots, R_n\}$, where each R_i is a string representing one of the n possible routes. For acyclic graphs such as the stroke pathway for the SINAP dataset this is straightforward via recursion. For a directed graph with cycles it is possible to repeat a cycle indefinitely so the number of possible routes is infinite. To avoid this we only allow each cycle to be repeated a finite number of times.

Due to the nature of our data, the events recorded are all covered by the pathway. In general, however, when using records from primary or secondary care, they may not be consistent with a care pathway event/transition graph. For a single patient we therefore extract all timed events from their record that occur on the pathway of interest, convert the events to characters, and concatenate the characters into strings according to their date-time order. The strings then represent the patient's journey through the care pathway.

If our dataset contains patients with multiple interactions with the pathway, we must then distinguish between distinct interactions with the care pathway by specifying a cut-off time. If ever the gap between adjacent patient events is greater than the cut-off, then we assume that the patient has left the pathway and any subsequent events form part of the patient's next visit to the pathway. This works well when the timescale of a pathway is shorter than the distances between them.

We then use the following string metrics to determine the distance between a patient pathway and each possible route through a care pathway.

Longest Common Subsequence

Formally, given two sequences $A = a_1 a_2 \cdots a_m$ and $B = b_1 b_2 \cdots b_n$ $(m \leq n)$ we say that A is a subsequence of B if there are indices $0 < j_1 < j_2 < \cdots < j_m \leq n$ such that $a_i = b_{j_i}$ is true for $i = 1,2, \ldots, m$.

Given two sequences $\boldsymbol{X}$ and $\boldsymbol{Y}$, $\boldsymbol{Z}$ is a common subsequence if it is a subsequence of both $\boldsymbol{X}$ and $\boldsymbol{Y}$. $\boldsymbol{Z}$ is the longest common subsequence (LCS) if $|\boldsymbol{Z}| >= |\boldsymbol{Z'}|$ for all common subsequences $\boldsymbol{Z'}$, where $|\boldsymbol{X}|$ is the length of $\boldsymbol{X}$. The LCS is not necessarily unique.

We are interested in which route through the pathway a patient took so we need to decide on a distance metric to convert the LCS into something more meaningful. An initial algorithm for a single patient is as follows:

1. Create a list of all the possible routes $\boldsymbol{R_1}, \ldots, \boldsymbol{R_n}$ through the care pathway
2. Filter the patient's events to just include pathway events and apply the time cut-off to give an event sequence $\boldsymbol{E} = \boldsymbol{E_1} \ldots \boldsymbol{E_m}$
3. For each route $\boldsymbol{R_i}$ calculate $\boldsymbol{L_i} = \boldsymbol{LCS}(\boldsymbol{R_i}, \boldsymbol{E})$
4. If $\boldsymbol{L_i} > \boldsymbol{0}$ calculate the distance $\boldsymbol{d_i} = \boldsymbol{max}(|\boldsymbol{R_i}|, |\boldsymbol{E}|) - |\boldsymbol{L_i}|$
5. Return the set of routes with the smallest distance

However, this only considers the discrepancy between the LCS and the pathway route; it doesn't take into account the length of the LCS. We can normalize the distance by either dividing by the LCS, or by dividing by the combined length of the two strings and step 4 above becomes either:

4. If $\boldsymbol{L_i} > \boldsymbol{0}$ calculate the distance $\boldsymbol{d_i} = \frac{\boldsymbol{max}(|\boldsymbol{R_i}|, |\boldsymbol{E}|) - |\boldsymbol{L_i}|}{|\boldsymbol{L_i}|}$

or

4. If $\boldsymbol{L_i} > \boldsymbol{0}$ calculate the distance $\boldsymbol{d_i} = \frac{\boldsymbol{max}(|\boldsymbol{R_i}|, |\boldsymbol{E}|) - |\boldsymbol{L_i}|}{|\boldsymbol{R_i}| + |\boldsymbol{E}|}$

We call these two methods LCS1 and LCS2 respectively.

Simple Edit Distance (Levenshtein Distance)

An alternative to the LCS is to consider the edit distance or Levenshtein distance[4]. The edit distance between two strings $\boldsymbol{X}$ and $\boldsymbol{Y}$ is the minimum number of operations required to convert $\boldsymbol{X}$ into $\boldsymbol{Y}$ where an operation is either: insert a character, delete a character or replace a character. When switching is allowed ($\boldsymbol{ab \rightarrow ba}$) the algorithm is the Damerau-Levenshtein[5,6]. The costs of inserting, deleting and replacing are given as $\boldsymbol{W_I}$, $\boldsymbol{W_D}$, and $\boldsymbol{W_R}$ respectively. It holds that $\boldsymbol{W_R \leq W_D + W_I}$, as we can always delete and then insert instead of substituting. By default the cost of each operation is 1.

The algorithm for our problem would be:

1. Create a list of all the possible routes $\boldsymbol{R_1, \ldots, R_n}$ through the care pathway
2. Filter the patient's events to just include pathway events and apply the time cut-off to give an event sequence $\boldsymbol{E = E_1 \ldots E_m}$
3. For each route $\boldsymbol{R_i}$ calculate the distance $\boldsymbol{d_i = LEV(R_i, E)}$
4. Return the set of routes with the smallest distance

Similarly we can do this for the Damerau-Levenshtein distance which we will notate as $\boldsymbol{d_i = DAM(R_i, E)}$.

Levenshtein Variants

Several versions of the Levenshtein Distance normalized to the length of the strings have been suggested. We notate the following as $\boldsymbol{NLEV}$[2].

$$\boldsymbol{NLEV(X,Y) = \frac{LEV(X,Y)}{|X| + |Y|}}$$

Also a normalized Levenshtein distance that satisfies the triangle equality and is therefore a true distance metric:

$$\boldsymbol{NLD(X,Y) = d_{N-GLD}(X,Y) = \frac{2 \cdot LEV(X,Y)}{\alpha \cdot (|X| + |Y|) + LEV(X,Y)}}$$

where α is whichever cost is greater out of insertion and deletion[3]. However, when $\boldsymbol{\alpha = 1}$, as is the case when all the weights are set to 1 by default, although the distances produced by NLD and NLEV will differ, the ordering of the matches will always be the same.

Finally, we consider a normalized version of the Damerau Levenshtein distance.

$$\boldsymbol{NDAM(X,Y) = \frac{DAM(X,Y)}{|X| + |Y|}}$$

We compare and contrast the different distance measures: LCS1, LCS2, LEV, DAM, NLEV, NLD and NDAM.

Data cleaning

Right censoring of the data is unlikely as once in hospital all end points are recorded. Most times in the data seem to be rounded to the nearest 10 or 15 minutes. This may potentially result in events appearing simultaneously or even out of order. There is also a risk of recollection or estimation bias as the data is often captured after the event.

When events occur at the same time there are several options available. The patient can be ignored, but this would result in a lot of data being excluded from the analysis. An alternative would be to perform the analysis on the data ordered randomly and let the string matching methods correct any discrepancies. However as we are interested in discovering the actual path the patient took, we can assume where possible the events occurred in the correct order.

For two events A and B on a pathway there is either: a one-way path from A to B, a one-way path from B to A, a path from A to B and B to A, or it is impossible to get from one to the other. For a group of events occurring at the same time if it is possible to order them in a unique way then we choose that as the order of the events. If it is not possible, because of a cycle or an unreachable node, then we discard that patient. For datasets where this is commonplace it may be better to include the patients discarded here and randomise the order of the cotemporaneous events. Alternatively we could just discard the events rather than the patient.

Similarly, events of unknown time, or those with just a date and not a time, can be inserted at the correct point of a patient record, if possible, or discarded if contradictions arise.

Data Management and Analysis Environment

The SINAP dataset was transferred to us via an encrypted external hard drive in CSV format. This was then uploaded to a Microsoft SQL Server 2008 database for analysis. Sequence matching was performed with C#.NET and all statistical analysis was done using R[23]. The sm library[24] was used for plotting density curves and the pROC[25] package was used for comparing Receiver Operating Characteristic (ROC) curves.

Results

Data Characteristics

The SINAP dataset contains 1078 patients of which 549 are female and 529 are male.

Table 1 shows the number of records that were cleaned using the above data cleaning process. Only 1 patient's route could not be uniquely re-ordered.

Table 1. Data cleaning results

Total patients	1078
Midnight events – able to insert	424
Simultaneous events – able to order	3
Midnight and simultaneous events – able to order	648
No midnight or simultaneous events – no need to order	2
Midnight events – unable to insert	1

There are 46 distinct pathways taken by the 1077 patients following time reordering. Table 2 shows the frequency of the top 10 patient pathways. The pathways that match the ICP are in bold. The route of GHDB should be a valid route however there are no patients in our cohort who followed this – suggesting this is not a valid route and the care pathway could be altered.

Table 2. Top 10 pathways – character sequences from figure 2.

Patient Record	Count	Comments
GHDEFIB	**275 (26%)**	**Valid route**
GHDFIB	**275 (26%)**	**Valid route**
GHDFEIB	122 (11%)	Valid route with E/F switched – lots of people so maybe a valid route.
GDHEFIB	63 (6%)	Valid route with D/H switched – can't be seen before you arrive.
GDHFIB	60 (6%)	Valid route with D/H switched – as above.
GHDEAFCIB	**56 (5%)**	**Valid route**
GHEDFIB	39 (4%)	Valid route with E/D switched – can't be imaged before first seen.
GHDEFACIB	37 (3%)	Valid with A/F switched.
GHFDIB	24 (2%)	D/F switched – can't arrive in specialist bed before being seen.
GDHFEIB	24 (2%)	D/H and E/F switched

It appears that there are some valid routes that aren't in our pathway. For those who don't get thrombolysed there are many people who arrive in a specialist stroke bed prior to their brain scan. Also there are many people who get "First Seen" before they arrive at the hospital. This seems nonsensical but could be valid if "First Seen" applied to GPs or ambulance staff. Finally there are patients who receive thrombolysis after getting to a specialist stroke bed which could also be a valid route. All other switches appear to be mistakes – for example having a brain scan prior to being first seen.

In order to determine how well each method works we must determine for each patient the most probable route taken. As our dataset is small we can do this manually by defining rules based on the data. We first assume that events that don't happen are rarely inserted and then classify the patients according to the following rules:

1. If a patient has thrombolysis or a follow up scan then assumes route GHDEAFCIB
2. Of those remaining, for any with a brain scan we assume route GHDEFIB

3. Of those remaining, for any with a stroke unit arrival or discharge we assume route GHDFIB
4. Of those remaining we assume GHDB

In addition to returning the correct result it is also of use if the distance measure returns a unique result. There will be situations where this isn't possible but in general string matching methods that return more unique results are preferable.

For each method, Table 3 gives the number of unique matches and the number of correct matches where a correct match is one that is both unique and matches with the routes we assume the patients actually followed.

Table 3. Number of unique and correct matches

Method	Unique Matches	Correct Matches	Correct
LEV	818 (75.95%)	645 (78.85%)	59.89%
DAM	853 (79.20%)	849 (99.53%)	78.83%
LCS1	882 (81.89%)	878 (99.55%)	81.52%
LCS2	1077 (100.00%)	1070 (99.35%)	99.35%
NLEV	1076 (99.91%)	841 (78.16%)	78.09%
NLD	1076 (99.91%)	841 (78.16%)	78.09%
NDAM	1076 (99.91%)	1068 (99.26%)	99.16%

The NLEV and NLD methods produce the same results as predicted. The ratio of correct matches to unique matches shows that the Damerau-Levenshtein and the longest common subsequence methods work excellently with >99% correct, whereas the Levenshtein variants only achieve 78-79%. It can also be seen that normalized methods are better at producing unique matches with LCS2 matching all pathways uniquely, while NLEV, NLD and NDAM only fail to give a unique answer for a single patient - actually a different patient for each method. Examining the difference between NLEV and NDAM shows that NDAM is correctly identifying pathways where events have been recorded out of sequence. As an example the patient record of GHDFEIB is correctly matched to GHDEFIB by NDAM, while NLEV matches it to GHDFIB.

When the values for unique correct matches are combined the normalized Damerau-Levenshtein and the second Longest Common Subsequence methods are best, correctly matching >99% of the patient pathways.

For these two methods we can split the pathways into two groups: correct and incorrect matches, where a correct match is when the algorithm uniquely identifies the route the patient traversed through the pathway. We then compare the groups under the null hypothesis that the mean 'string' distance between them is equal. The density plots in Figure 3 demonstrate the data we want to contrast are not drawn from normal or symmetrical distributions, indeed the distributions of string distances are quite different for matches compared with non-matches. Thus we make the contrast with a non-parametric (Matt-Whitney) method[26], demonstrating statistically highly significant differences for both NDAM ($P < 0.0001$) and LCS2 ($P < 0.0001$) metrics.

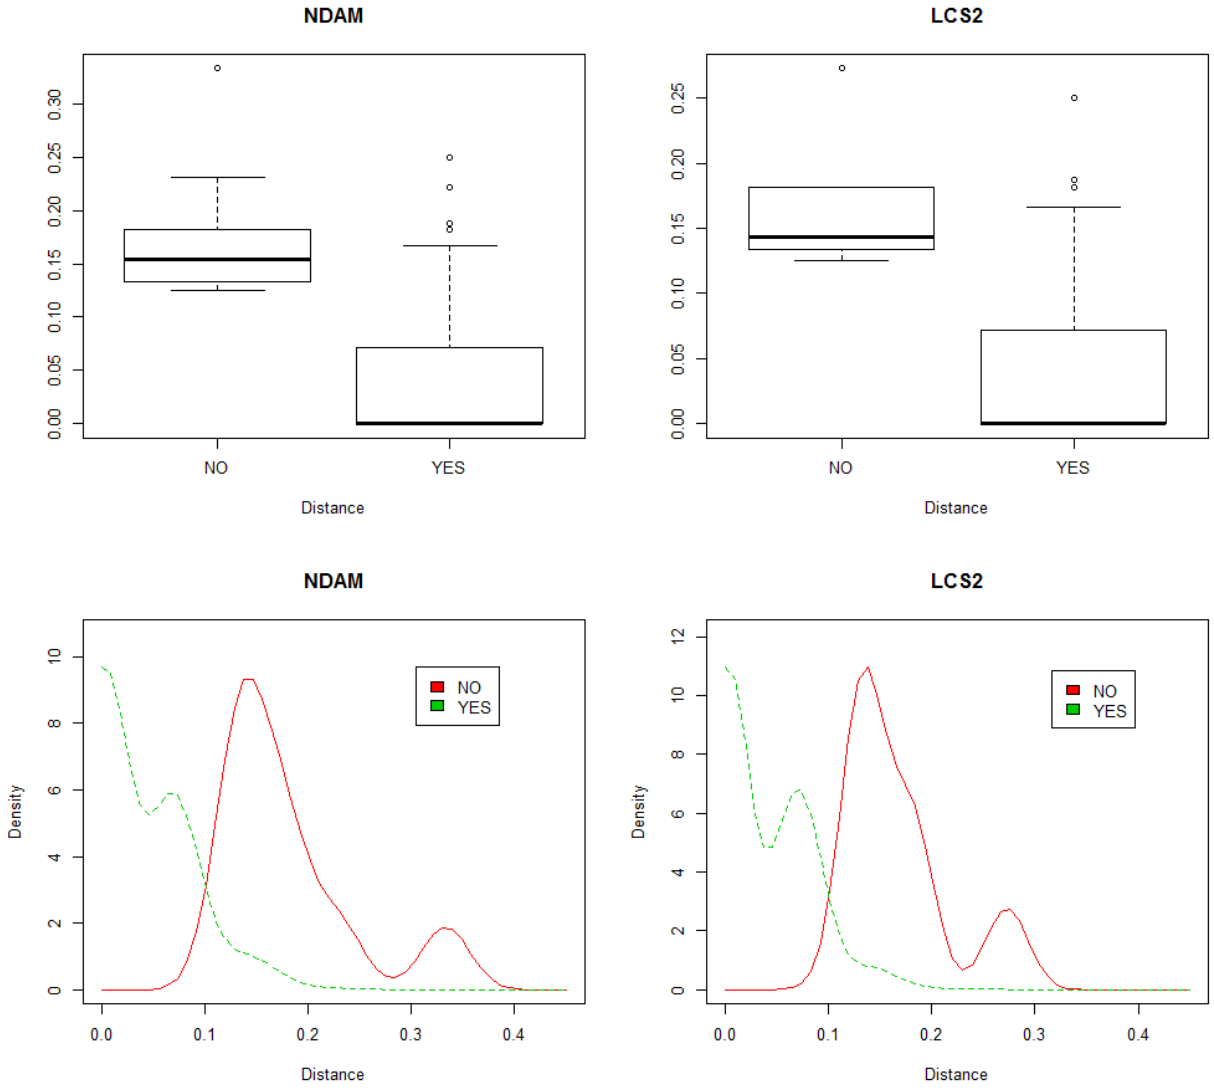

Figure 3: Box (top) and density (bottom) plots of string distances for matches (YES) and non-matches (NO) for NDAM and LCS2 metrics.

Finally, we compare NDAM, LCS2 and NLEV string distance metrics with regard to their classification accuracy for our care pathway journeys. Figure 4 shows the ROC curves for each metric with our test dataset, and the 95% confidence intervals for the areas under the curves: the more detailed comparison of the two most accurate metrics (NDAM and LCS2) is the Mann-Whitney result above.

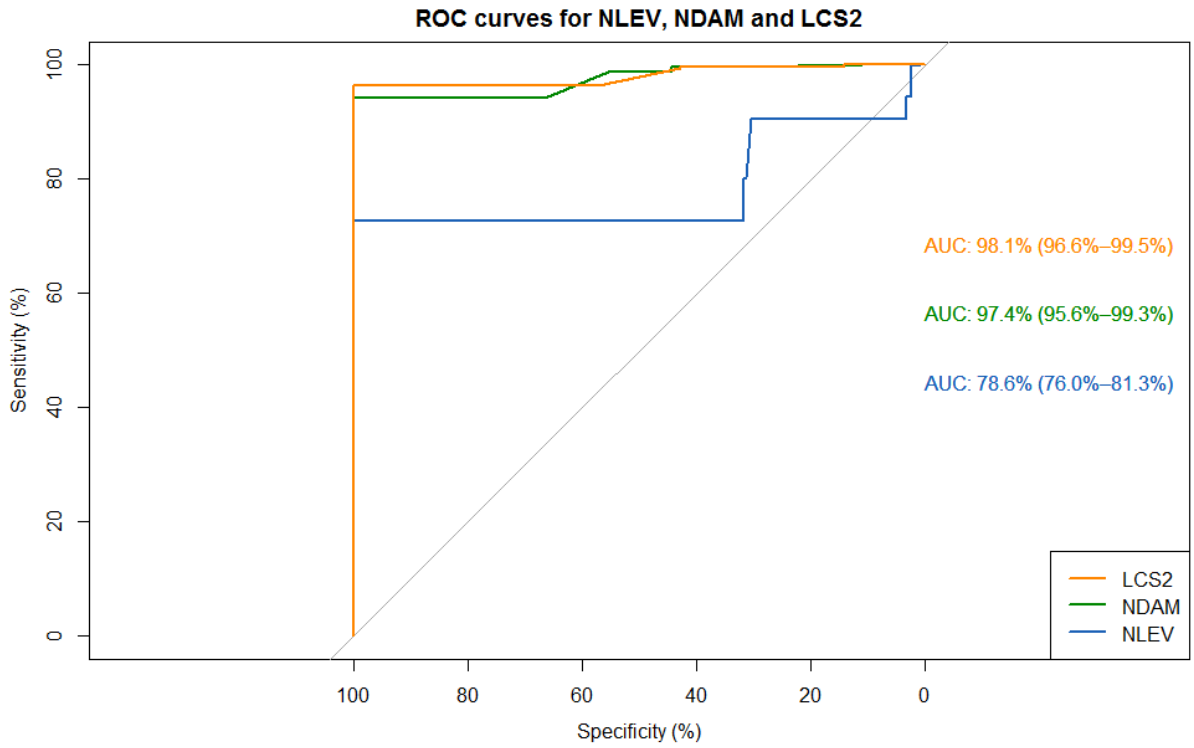

Figure 4: Receiver Operating Characteristic (ROC) curves for NDAM, NLEV and LCS2 string distance metrics with 95% confidence intervals for the areas under the curves.

Discussion

Distance Weighting

The operations in the Damerau-Levenshtein string metric can be weighted. Given the nature of our dataset it is more likely that records were omitted or out of order, than miscoded. If we are sure of this we can change the weighting of the operations accordingly – an option that is possible with the NDAM and not the LCS2 method. By doubling the weight associated with deleting a character, therefore making it less likely that matches will feature deletions, of the 1077 patients we yield 1077 unique matches of which 1074 are correct. Weighted NDAM then becomes the most accurate way of predicting a patient's route.

Generalization

The string matching process described here operates on a graph based representation of a care pathway. Therefore the methodology is theoretically applicable, although untested, to any process or workflow that can be represented as a graph, in healthcare and beyond.

Future work

There are several factors unstudied in this paper that will affect the overall success of the method. The size and shape of the graph is a factor, as is the quality of the data. Further work is needed to determine which graph shapes work well with this method. Finally, the next stage of our work is to determine how the distance a patient is from their care pathway predicts their outcomes.

Conclusion

String matching would seem to be a highly successful way to determine which route a patient followed in a care pathway. Normalized distance functions should be used to ensure high numbers of unique matches. For clinical data where the chance of events occurring, or being recorded, in the wrong order is high, the Damerau-Levenshtein or Longest Common Subsequence methods should be used in preference to the Levenshtein distance.

Desiderata for an authoritative Representation of MeSH in RDF

Rainer Winnenburg, PhD, Olivier Bodenreider, MD, PhD
National Library of Medicine, National Institutes of Health, Bethesda, Maryland, USA
{rainer.winnenburg|olivier.bodenreider}@nih.gov

The Semantic Web provides a framework for the integration of resources on the web, which facilitates information integration and interoperability. RDF is the main representation format for Linked Open Data (LOD). However, datasets are not always made available in RDF by their producers and the Semantic Web community has had to convert some of these datasets to RDF in order for these datasets to participate in the LOD cloud. As a result, the LOD cloud sometimes contains outdated, partial and even inaccurate RDF datasets. We review the LOD landscape for one of these resources, MeSH, and analyze the characteristics of six existing representations in order to identify desirable features for an authoritative version, for which we create a prototype. We illustrate the suitability of this prototype on three common use cases. NLM intends to release an authoritative representation of MeSH in RDF (beta version) in the Fall of 2014.

1 Introduction

In their seminal paper in 2001 [1], Berners-Lee et al. offer a vision of the Semantic Web featuring use cases in healthcare and the life sciences, such as accessing treatment information, finding healthcare providers and scheduling appointments. Later, Ruttenberg and members of the Health Care and Life Sciences Interest Group (HCLSIG) of the World Wide Web Consortium have highlighted the potential of the Semantic Web for supporting translational research [2].

In the era of Linked Open Data, the biomedical domain represents a significant portion of the Linked Open Data cloud [3], a growing collection of interoperable resources supported by Semantic Web technologies. As shown in Figure 1, the biomedical portion of the Linked Open Data cloud (depicted in pink) included over 40 datasets in 2011 and is still growing as datasets become available in formats suitable for Linked Data (e.g., RDF – the Resource Description Framework).

Some data providers have made their resources available in RDF (e.g., UniProt [4]). In many cases, however, the Semantic Web community has stepped up and transformed existing resources to RDF so they can participate in the Linked Open Data (LOD) cloud. According to the statistics published on the LOD cloud website [5], as of August 2011, out of the 295 datasets in the LOD cloud only 113 (39 %) were published by the data producers themselves, while 180 (61 %) were published by third-parties. For example, LinkedCT is a Linked Data version of the National Library of Medicine's registry of clinical trials, ClinicalTrials.gov, created and maintained by researchers at the University of Toronto [6], and used in several projects, including clinical registries [7].

While Linked Open Data is arguably the most visible part of the Semantic Web, Semantic Web technologies have permeated many industries, including libraries. For example, the Library of Congress has recently initiated the Bibliographic Framework Initiative (BIBFRAME) [8], an attempt to replace the legacy MARC 21 format [9] with Semantic Web technologies for the representation and exchange of bibliographic data [10]. This new framework could leverage RDF representations of legacy authority files, such as the Library of Congress Subject Headings and the National Library of Medicine's Medical Subject Headings (MeSH) [11], for the annotation of bibliographic records. However, MeSH is made available by its developer in XML, MARC, and ASCII flat files, as well as through the Unified Medical Language System (UMLS) Metathesaurus [12], but not in RDF.

This initiative prompted us to revisit our earlier attempt to produce an RDF version of MeSH, in the objective of establishing desiderata for an authoritative representation of MeSH in RDF. More specifically, we explore the Linked Open Data cloud for RDF versions of MeSH contributed by the community, including our own, and we analyze their characteristics in order to identify desirable features for an authoritative version. We propose a prototype RDF representation of MeSH that meets these criteria, and we illustrate its usefulness through three common use cases. NLM intends to release an authoritative representation of MeSH in RDF (beta version) in the Fall of 2014.

2 Background

2.1 Semantic Web technologies

The Semantic Web is an extension of the current Web [1, 13]. Underlying the Semantic Web are a set of technologies, including Uniform Resource Identifiers (URIs) – identifiers for resources on the Web [14], the Resource Description Framework (RDF) – a format for representing (and making statements about) Web resources [15], and the SPARQL query language for RDF repositories [16]. Ontologies provide the vocabulary and shared semantics required for annotating resources and to support inference. RDF and the Web Ontology Language (OWL) are the W3C standards for encoding data/knowledge [17]. The Simple Knowledge Organization System (SKOS) is recommended for the representation of thesauri and similar artifacts [18].

RDF describes information in the form of subject-predicate-object triples. This enables information to be represented in the form of a graph. The graph can then be queried using SPARQL. RDF has multiple serialization formats, including RDF/XML, N-Triples, Turtle and, most recently, JSON-LD. The two main distribution mechanisms for RDF data are making the RDF datasets available for download and providing a "SPARQL endpoint", i.e., a live service to which queries can be made.

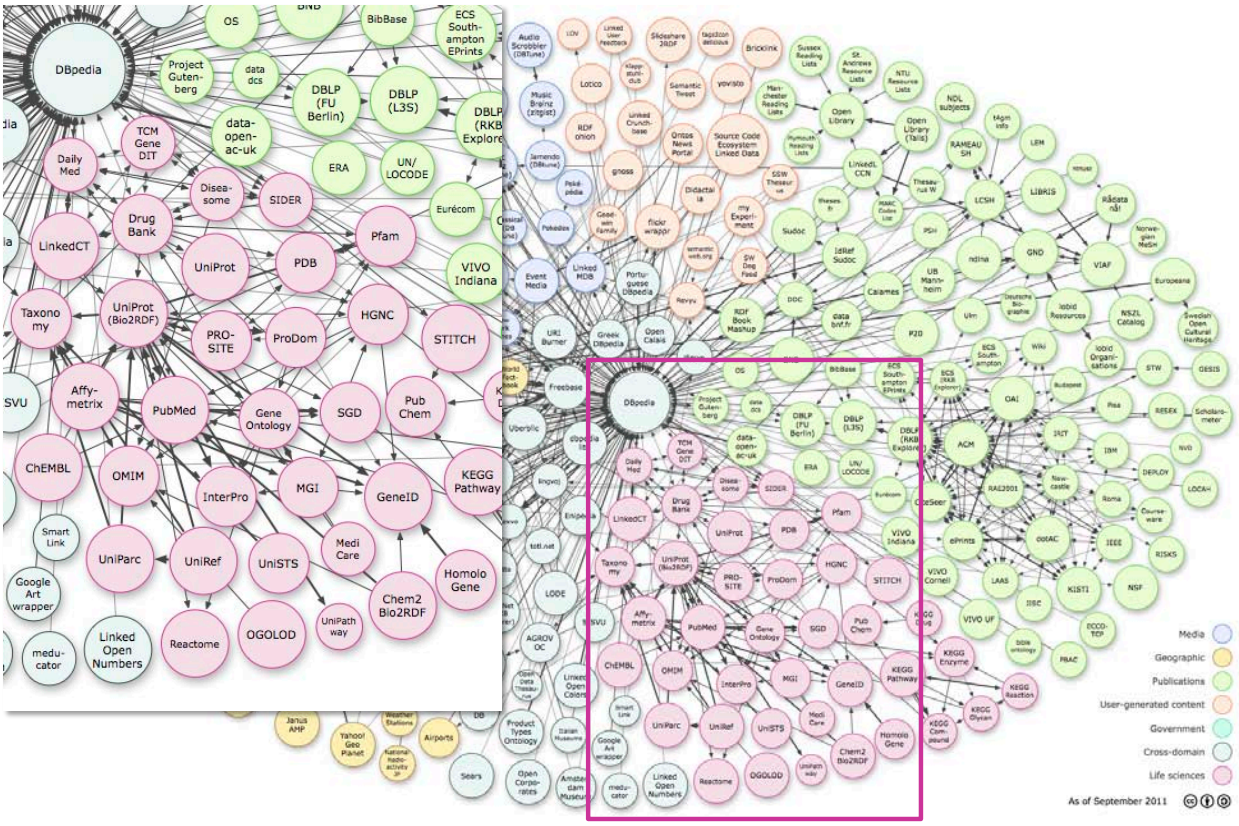

Figure 1. Linked Open Data cloud as of September 2011 (with close-up view on the life sciences portion)

2.2 Medical Subject Headings (MeSH)

The MeSH thesaurus is a controlled vocabulary produced by the National Library of Medicine (NLM) and used for indexing, cataloging and searching for biomedical and health-related information and documents [11]. MeSH consists of three main record types: Descriptor records, Qualifier records and Supplementary Concept records (SCRs). Each record has a unique identifier. Descriptors, also known as Main Headings, are mostly used to indicate the subject of an indexed item in NLM's MEDLINE bibliographic database and other databases. *Acquired immunodeficiency Syndrome* (D000163) is an example of a descriptor. Qualifiers, also known as subheadings, are used for indexing and cataloging in conjunction with descriptors, to indicate which specific aspect of a descriptor is discussed. For example, the qualifier *adverse effects* can be used with drug descriptors to index adverse drug events. In addition to de-

scriptors, SCRs are used by annotators to index new or less frequently occurring terms in the literature. All SCRs are connected to at least one descriptor ("heading mapped to" in MeSH parlance). In some cases, SCRs can be mapped to multiple descriptors or to descriptor-qualifier combinations. MeSH is easily accessible via the MeSH Browser [19] and made available by NLM for download in various formats, including XML, MARC, and ASCII flat files, as well as through the Unified Medical Language System (UMLS) Metathesaurus [12].

Three features of MeSH make it non-standard. These idiosyncratic features are: a 3-level structure (descriptor / concept / term), a contextual hierarchical structure and the need in common use cases for entity combinations (descriptor-qualifier combinations) that are not materialized in MeSH.

3-level structure. Instead of the traditional concept-term terminological model of most thesauri, MeSH uses a 3-level structure. In addition to concepts and terms (i.e., concept names), MeSH also defines descriptors, i.e., small aggregates of concepts grouped together as needed to support indexing and retrieval. For example, the MeSH descriptor *Ofloxacin* (D015242) groups several concepts, including the main concept identified by M0023430 (with terms *Ofloxacin* and *Ofloxacine*), the concept for a salt of this drug, M0329515 (with term *Ofloxacin Hydrochloride*), and the concept for the experimental form of this drug before it was marketed, M0023432 (with name *Ru-43280*). This 3-level structure is not amenable to representation with standard terminological models, such as SKOS, which only accommodates concepts and terms.

Contextual hierarchical structure. In addition to a non-standard terminological model, MeSH also uses a non-standard hierarchical organization. The hierarchy among MeSH descriptors is indicated through "tree numbers" assigned to descriptors. Tree number inclusion reflects that the descriptor with the longer tree number is narrower than that with the shorter tree number. For example, the tree number for *Liver* [A03.620] has an additional node (.620) compared to that of *Digestive System* [A03], indicating the narrower relation between the two. Note that tree numbers are not the unique identifiers of descriptors. Descriptors often have multiple tree numbers reflecting particular aspects of the descriptors, each aspect being assigned specific broader and narrower descriptors. For example, the descriptor *Eye* (D005123) has two tree numbers, A01.456.505.420 and A09.371. In the A01 tree, *Eye* is narrower than *Head* [A01.456] and broader than *Eyebrows* [A01.456.505.420.338] and *Eyelids* [A01.456.505.420.504], whereas, in the A09 tree, *Eye* is narrower than *Sense Organs* [A09] and broader than *Eyelids* [A09.371.337], *Retina* [A09.371.729], *Uvea* [A09.371.894] and nine other descriptors. Note that, although *Head* is broader than *Eye* (A01 tree), some descendants of *Eye* in the A09 tree (e.g., *Retina*) do not have *Head* as their ancestor. For all practical purposes, the broader/narrower relationship among MeSH descriptors is not transitive.

Descriptor-qualifier combinations. Finally, although MeSH represents descriptors and qualifiers as separate entities, common use cases of MeSH require combinations of descriptors and qualifiers. Chief among them is MEDLINE indexing, where descriptor-qualifier combinations are assigned to articles from the biomedical literature by indexers. For example, the descriptor-qualifier combination *Levofloxacin/adverse effects* is found as an index term for this report of a dermatological adverse drug event titled "Case of drug-induced bullous pemphigoid by levofloxacin" [20]. As mentioned earlier, MeSH itself uses descriptor-qualifier combinations to relate supplementary concept records to descriptors (and qualifiers). For example, the SCR for the drug *antofloxacin* (C522674) is mapped to *Ofloxacin/analogs & derivatives*, combining the descriptor *Ofloxacin* and the qualifier *analogs & derivatives*.

3 Related work

In the absence of an authoritative representation of MeSH in RDF from the NLM, there have been several efforts over the past few years to make MeSH available for the Sematic Web, starting from various sources, making use of different transformation techniques, and adopting different schemas and models. In the following, we review these existing representations of MeSH in RDF critically, in order to examine how the developers of RDF representations of MeSH have coped with the challenges associated with representing the three idiosyncratic features of MeSH discussed earlier. References for the six sources can be found in Table 1.

3.1 Original MeSH-SKOS

In 2004, Van Assem et al. generated what is probably the first representation of MeSH in RDF, leveraging the Simple Knowledge Organization System (SKOS) RDF Schema [21]. In addition to the RDF resource itself, these researchers made available the script they had developed to create it. Although the representation they produced was essentially for proof-of-concept purposes and was never updated, interested users can still apply their transformation to more recent versions of MeSH.

Because SKOS is a concept-based model, it cannot do justice to the distinction between descriptors and concepts in MeSH. As a consequence, all terms are directly attached to the descriptor in the SKOS representation, which may constitute a limitation for some applications. Hierarchical relations among MeSH descriptors are provided through *skos:broader* relations between descriptor URIs. Descriptor-qualifier combinations are not materialized. Of note, this proof-of-concept version does not provide a complete representation of MeSH (e.g., supplementary concept records are omitted).

3.2 Science Commons MeSH-SKOS and qualified-headings

In 2006, the Van Assem transformation was slightly modified by Science Commons researchers for use in the HCLSIG 2007 demo and was part of a mashup system that seeks to help the process of bioinformatics knowledge integration [22]. Additionally, Science Commons provides a companion resource (mesh/qualified-headings), in which MeSH descriptor-qualifier combinations are materialized, e.g., *mesh:D000001Q000008 skos:prefLabel "Calcimycin - administration & dosage"*. Although the data on the Science Commons website is for MeSH 2008, the script for creating the resources is available from the website.

The main MeSH-SKOS has the limitations of representations of MeSH in SKOS discussed earlier. Although descriptor-qualifier combinations are not materialized in the main SKOS representation, they are made available as a separate resource. This feature makes it possible to refer to these combinations in the representation of MEDLINE citations developed by the same researchers, in which *has-as-major-mesh* and *has-as-minor-mesh* relations are asserted between MEDLINE records and descriptor-qualifier combinations in MeSH. This representation is interesting as it reflects a specific use case, i.e., MEDLINE indexing, where citations are often indexed with descriptor-qualifier combinations. This representation is the only one we found that treats descriptor-qualifier combinations as first-class entities, with their own URIs.

3.3 Bio2RDF MeSH

Started in 2006, the Bio2RDF project uses Semantic Web technologies to provide linked data from publicly available databases in the life sciences [23, 24]. As of early 2014, there are 28 datasets available, including MeSH, linked together with normalized URIs, and sharing a common ontology. The current representation of MeSH in Bio2RDF is derived from the original MeSH 2014 ASCII flat files, containing all descriptor, supplementary concept, and qualifier records, their relations, and metadata.

Bio2RDF MeSH does not distinguish between descriptors and concepts in MeSH and all terms are directly attached to the descriptor as literals through proprietary *entry-term* relations. Hierarchical relations among MeSH descriptors are provided through *rdfs:subClassOf* relations, while MeSH only asserts broader/narrower relations. Moreover, Bio2RDF hierarchical relations are between materialized "tree-number classes" (i.e., specific aspects of the descriptors), e.g., *mesh:A08.186.211.132.93 rdfs:subClassOf mesh:A08.186.211.132*. Descriptors are linked to these tree-number classes through *mesh_vocabulary:mesh-tree-number* relationships. Descriptor-qualifier combinations are not materialized and supplementary concept records are mapped to a literal representation of the combination instead (e.g., *mesh:C014481 mesh_vocabulary:heading-mapped-to "Codeine/*analogs & derivatives"*), which is suboptimal from a Linked Data perspective.

3.4 NCBO BioPortal UMLS-MESH

Developed by the National Center for Biomedical Ontology at Stanford University since 2006, BioPortal is an open repository of biomedical ontologies made accessible via web services and web browsers [25]. BioPortal now offers RDF versions of all its ontologies. It actually provides two versions of MeSH. The main version (MESH) is derived from various files from the Unified Medical Language System (UMLS) [12, 26] Metathesaurus distribution and is currently being used in more than ten projects (e.g., the Drug Interaction Knowledge Base). UMLS-MeSH is available for the 2014 version of MeSH.

Like most MeSH representations, the version in BioPortal does not distinguish between descriptors and concepts in MeSH. MeSH descriptors are subclasses (*rdfs:subClassOf*) of their broader descriptors according to the MeSH tree number hierarchy. The tree numbers themselves are linked to the descriptors through annotation properties. Descriptor-qualifier combinations are not materialized. Supplementary concept records (SCRs) are mapped to descriptors through *mapped_to* relations and, independently, to qualifier through *has_mapping_qualifier* relations, where applicable. Decoupling the mapping of SCRs to descriptors and qualifiers is problematic when an SCR is mapped to multiple descriptor-qualifier combinations, because there is no explicit statement of the association between descriptors and qualifiers in this case. Additionally, supplementary concept records are mapped to literals

created for descriptor-qualifier combinations (e.g., *"D007830/Q000002"*), which, here again, is suboptimal from a Linked Data perspective.

3.5 NCBO BioPortal RH-MeSH

The "Robert Hoehndorf version of MeSH" (RH-MeSH) is the second version of MeSH found in BioPortal. Unlike the version of MeSH derived from the UMLS presented earlier, this version was created for a specific purpose, i.e., to facilitate the use of the descriptor and SCR hierarchy. It is used in the cross-species phenotype network, PhenomeNet. RH-MESH is represented in OWL. All MeSH descriptors and SCRs are classes as expected. Additionally, tree-numbers (representing specific aspects of descriptors) are also treated as classes and linked to other tree number classes through *rdfs:subClassOf* relationships. SCRs are represented as subclasses of descriptors. MeSH descriptors for drugs are also subclasses of the descriptors corresponding to their pharmacological actions. Except for class labels, this version of MeSH does not expose any other properties of the descriptors (e.g., definition). RH-MeSH is available for the 2014 version of MeSH.

While blurring the distinction between descriptors and SCRs (and even between descriptors and their tree numbers), this representation of MeSH provides an easy way for traversing the tree of MeSH entities. However, because it assumes that the descriptors are linked through subclass relationships, which is not what MeSH asserts, it contains inaccurate assertions (e.g., *Liver* subclass of *Digestive system*). Moreover, it links SCRs to descriptors (and not descriptor-qualifier combinations), and considers these links subclass relations (not mapping relations as indicated in MeSH), which also results in inaccurate assertions. For example, the MeSH assertion *Acrorenal Syndrome* mapped to *kidney/abnormalities* (descriptor-qualifier combination), is wrongly translated into *Acrorenal Syndrome* subclass of *kidney*.

3.6 MOR MeSH baseline

In 2009, in order to support internal research projects in the Medical Ontology Research (MOR) group at NLM, we created a fully automated process to transform the native XML representation of MeSH into RDF, based on EXtensible Stylesheet Language Transformations (XSLTs). Our goal with this representation was that it be close to the original XML representation and lossless. In other words, we made sure that all the information and only the information in the source XML had been captured during the transformation into RDF. We have updated this simple baseline representation regularly by applying our XSLTs to each new release of MeSH, but have kept both the XSLTs and RDF output internal to our research group.

The 3-level structure of MeSH with all relations between descriptors, concepts, and terms is preserved in this version. The descriptor hierarchy has been created for convenience, but kept in a separate graph, because it was not present in the native XML representation. The linkage of Supplementary Concept Records to descriptors and qualifiers is implemented through blank nodes rather than materialized descriptor-qualifier combinations, which is suboptimal as blank nodes lack shared semantics.

Table 1. Availability of existing RDF representations of MeSH

4 Methods and Results

In this study we performed a review of existing representations of MeSH in RDF, established a list of desirable features for an authoritative representation, and implemented a prototype version of MeSH in RDF according to these criteria.

4.1 Analysis of the characteristics of existing RDF representations of MeSH

We conducted a manual analysis of the six existing representations of MeSH in RDF introduced in the Background section. We downloaded all representations that we reviewed and accessed them through their SPARQL endpoint whenever possible. However, we did not test any of the transformation scripts and did not create any local MeSH representations based on those.

We established a list of the characteristics of these resources, while focusing on the following features. We used the latest release date as an indication of the currency of the resource (the 2014 version of MeSH, available since September of 2013, was expected to be found). We categorized a representation as lossless only if the complete information provided in MeSH was exposed in the RDF representation. More specifically, we expected coverage of all three components of MeSH (descriptors, qualifiers and SCRs), as well as all important features (e.g., definitions). We also expected the semantics of MeSH relations to be preserved (e.g., hierarchical relations among descriptors represented as broader relations, not subclass relations). We noted the format(s) in which the resources were made available (e.g., RDF, OWL) and which specific terminological model or schema was used (e.g., SKOS). Some resources were developed as proof-of-concept and never intended to be maintained regularly, while others were in stable or beta version. We recorded this distinction. Whenever available, we added the information about the generation mechanism, as well as the original MeSH source used for creating the RDF representation (MeSH XML, MARC, or ASCII flat files, or UMLS Metathesaurus files). In terms of dissemination, we recorded whether the RDF resources were available for download or could be queried through a SPARQL endpoint, and whether the developers made the scripts used for the generation of RDF available to the community. Finally, we recorded how the idiosyncratic features of MeSH had been represented, especially hierarchical relations and descriptor-qualifier combinations.

Table 2. Characteristics of existing RDF representations of MeSH

Name	Latest Release Date	Lossless	Format	Status	Conversion	Dissemination	Features	
							Descriptor-Qualifer comb.	Hierarchical relations
Original MeSH-SKOS	2004	No	RDF (SKOS)	Proof-of-concept	Perl script, XSLT, XML	Download, Script	No	Yes (broader)
Science commons mesh-skos and qualified-headings	2008	No	RDF (SKOS)	Proof-of-concept	Using eswc06 Perl script, XSLT, XML	Endpoint, Script	Yes	Yes (broader)
Bio2RDF MeSH	2014	No	RDF	stable	PHP, ASCII	Endpoint, Download, Script	No* (as literals)	Yes (subclass)
NCBO Bioportal UMLS MESH	2014 (UMLS 2014AA)	UMLS view on MeSH	RDF	stable	UMLS Metathesaurus files	Endpoint, Download	No* (two separate relations and literals)	Yes (subclass)
NCBO Bioportal RH-MESH	2014	No	OWL	Beta	unspecified	Endpoint, Download	No	Yes (subclass)
MOR MeSH baseline	2014	Yes	RDF	Internal	XSLT	Used only internally	No* (through blank nodes)	Yes* (broader, in a separate graph)

The results of our analysis are summarized in Table 2. Four resources are up to date (i.e., reflect MeSH 2014 as of July 2014), but this was not the case at an earlier stage of our exploration a few months ago. The other two versions, developed for proof of concept, are not expected to be up to date. Most versions only capture a subset of the MeSH features, rather than all the details present in the original source. Two versions use OWL, one SKOS, and the other three use RDF with no specific terminological model. Except for one, the providers offer the resource for download, and most also provide a SPARQL endpoint. The transformation script is made available in three cases. Regarding the features of special interest to us, we found that only one resource materializes descriptor-qualifier combinations in a way that is suitable for linking to a MEDLINE dataset. While all resources investigated offer some kind of representation of hierarchical relations between MeSH descriptors, it is worth noting that the semantics of hierarchical relations had been reinterpreted by half of the providers as subclass relations, as opposed to broader relations.

4.2 Desirable features for an authoritative representation of MeSH in RDF

Based on our analysis of the characteristics of existing representations of MeSH in RDF, we compiled a list of desirable features for an authoritative representation of MeSH in RDF. Not mentioned in this list are the best practices for publishing linked data, such as guidelines for creating URIs, which are applicable to all RDF datasets, not only authoritative representations of vocabularies such as MeSH [27].

Completeness: Given the multiplicity of use cases for MeSH, it is likely that a representation of MeSH in RDF will be used in different ways by different users. Therefore, we believe it is best to provide a systematic representation in RDF of all features present in the XML version of MeSH. At a minimum, the authoritative representation of MeSH in RDF should represent those features exposed through the UMLS, as some sources do. However, representing only a subset of the MeSH entities (e.g., omitting the SCRs) would not be an option for most use cases.

Usability: As mentioned earlier, the structure of MeSH is too complex to be represented with the terminological model of SKOS. On the other hand, an RDF representation limited to the features of MeSH explicitly present in the XML version (such as our original baseline version), lacks the convenience of exposing important features, including hierarchical relations among descriptors, and materialized descriptor-qualifier combinations. Usability of the authoritative representation of MeSH in RDF should be analyzed in light of major use cases, which for MeSH include the role it plays in indexing and retrieval of the biomedical literature (MEDLINE). As illustrated by RH-MeSH, the authoritative representation could be extended by users in order to further facilitate traversal of the MeSH tree (at the expense of the original semantics of some MeSH relations).

Linkability: The authoritative representation of MeSH in RDF is meant to be linked to other resources in the Semantic Web. Although an authoritative version of MEDLINE in RDF has not been released yet, it would be a prime candidate for interoperating with MeSH in the Linked Open Data cloud. This requires coordinated development of resources within the institution developing these resources. Moreover, it requires harmonization of base URIs and predicates wherever possible. The representation provided by Science Commons, illustrated in Figure 2, prefigures what a MeSH-MEDLINE combined subset would look like.

```
@prefix c: <http://purl.org/science/owl/sciencecommons/> .
@prefix m: <http://purl.org/commons/record/mesh/> .
<http://purl.org/commons/record/pmid/11696761>
         c:has-as-minor-mesh m:D000368 ;
         c:has-as-minor-mesh m:D002292 ;
         c:has-as-minor-mesh m:D002292Q000150 ;
```

Figure 2. MeSH-MEDLINE combined subset as provided by Science Commons

Currency: A new version of MeSH becomes available each year and resources such as MEDLINE are synchronized with new versions of MeSH once a year. The authoritative representation of MeSH in RDF needs to be available in a timely fashion, and in coordination with related resources.

Availability: The authoritative representation of MeSH in RDF should be made available for download alongside the XML representation and other legacy representations. Users could load MeSH locally in an RDF database. Additionally, the resource should be available through a SPARQL endpoint so that local installation is not a requirement for use. (To some extent, this dual distribution mechanism is no different from the provision of datasets for download and web services, as is the case for the UMLS, for example.)

Transparency: Besides providing the RDF data for download, the transformation programs used to generate the RDF resource (e.g., scripts, XSLT, etc.) should be made available. This will give users insights into the transfor-

mation process and allow them to create RDF files locally, or create variants as required by their specific use cases. Exposing the transformation process might also help the community detect potential errors and suggest improvements.

4.3 Towards an authoritative representation of MeSH in RDF

The source version of MeSH we used in our prototype is the XML version (i.e., the 2014 MeSH XML files). The transformation rules from XML to RDF were coded using the XSLT (Extensible Stylesheet Language Transformations) language. The DTD file of each record type (Descriptor, Supplementary Concept Record, Qualifier) informed the creation of an XSLT for each type of MeSH record. The XSLT files were applied to the source XML files using the saxon XSLT processor. In addition to the features of MeSH explicitly represented in the XML file (and already present in our earlier baseline version), we chose to represent some other features for convenience purposes, i.e., in order to increase usability. We created a hierarchy among descriptors using the *skos:broader* relationship. We also elected to materialize descriptor-qualifier combinations for all the allowable qualifiers of each descriptor, in order to support upcoming representations of MEDLINE in RDF.

Our current prototype version of an authoritative representation of MeSH in RDF has the following features:

- Completeness: The losslessness of our transformation can easily be demonstrated by regenerating the original XML from the RDF using another set of XSLT files.
- Currency: The XSLT can easily be applied to any new version of MeSH. No changes to the XSLT are required unless changes are made to the XML DTD of the MeSH records. Because the transformation is completely automated and fast, it is conceivable to produce a nightly build reflecting the addition of supplementary concept records (e.g., for internal use by NLM for indexing purposes).
- Availability: The RDF file can easily be made available on the MeSH website, alongside the XML and legacy representations. Additionally, NLM intends to make it available through a SPARQL endpoint.
- Transparency: The XSLT files can be distributed on the MeSH website together with the XML and RDF versions.

It is difficult to comment on linkability at this prototype stage. However, the recently created NLM Linked Data Infrastructure Working Group will oversee the development of the final version of the authoritative representation of MeSH in RDF and of the other RDF datasets NLM intends to make available as Linked Data. The addition of descriptor-qualifier combinations to the prototype representation of MeSH in RDF prefigures the availability of an interoperable version of MEDLINE in RDF.

Usability is probably the most difficult criterion to fulfil and evaluate, due to the multiplicity of use cases for MeSH, beyond NLM's own use cases for indexing and retrieval of the biomedical literature. As already mentioned, while a complete, lossless version may best serve some complex use cases, other, more common use cases may be best served by simpler representations. Input from the community will help NLM determine which trade-offs to adopt for the final representation.

5 Discussion

In the following we provide several use cases illustrating the application of our prototype authoritative representation of MeSH in RDF. We also discuss current limitations and future directions for our work.

5.1 Use cases for an authoritative representation of MeSH in RDF

Currency: The Bibliographic Framework Initiative (BIBFRAME) [8, 10] initiated by the Library of Congress (LOC) provides a model for expressing and connecting bibliographic data on the web to replace the current standard for bibliographic exchange (MARC 21) [9]. BIBFRAME catalogues works and their instances, and associates them with authorities, which are resources that represent persons, organizations, topics, etc., (e.g., LOC subject headings can be accessed through the URI namespace <http://id.loc.gov/authorities/subjects/>). MeSH, as an authoritative resource, should be used for providing authorities for biomedical subjects (such as diseases, treatments, etc.). URIs for descriptors and SCRs should be added to catalog records where applicable. In BIBFRAME, topics can be assigned in combination with publication types. An extension of the representation of MeSH in RDF – possibly local to a given cataloging site – could include descriptor-publication type combinations (similar to the descriptor-qualifier combinations included in our prototype).

Quality assurance of MeSH: One of the key advantages of linked data is the possibility to link information across different data sources. But even for a single, locally available RDF graph, SPARQL queries can help gather infor-

mation from the data, which would be difficult to retrieve using other representations (e.g. flat files, XML). We helped the MeSH development team detect and remove cyclic relationships in the MeSH graph and assess that the 2014 version of MeSH is acyclic. Other applications include summarizing all supplementary concept records for a given pharmacologic action.

Linked data applications: In a recent collaboration with the FDA Center for Drug Evaluation and Research (CDER), we developed a novel analytic tool for quantitative drug-adverse event (ADE) safety signal detection based on mining the biomedical literature (MEDLINE). We leveraged the MeSH indexing terms to extract associations between co-occurring drug entities (in the context of adverse effects) and clinical manifestations (induced by chemicals). Information about ADEs is captured by different kinds of entities in MeSH (main headings, pharmacological actions, and supplementary concept records) and their inter-relations. In addition to the representation of MeSH in RDF, we created a prototype version of MEDLINE in RDF for the subset of articles under investigation in our study. The use of Semantic Web technologies enabled us to perform complex queries across the MeSH and MEDLINE datasets and greatly facilitated our work.

5.2 Limitations and future work

This prototype of an authoritative representation of MeSH in RDF is current and complete, but not final. Important improvements have been made already to our original baseline version, including the explicit representation of the hierarchical relations among descriptors (to improve usability) and the materialization of descriptor-qualifier combinations (to improve linkability with MEDLINE). However, additional editorial changes have to be made. For example, base URIs, namespaces and predicate names were chosen somewhat arbitrarily in the early development phase, where the focus was on demonstrating feasibility and scalability of the transformation method. However, these elements become important as this prototype is evolving into the authoritative representation of MeSH in RDF. Feedback from the user community will also inform future developments.

In order to accommodate some features of the XML version, our baseline version had introduced blank nodes to represent, for example, entry combinations and concept relations. While developing the current prototype, we critically reexamined earlier design choices and found that in most cases blank nodes were unnecessary or could be replaced by materialized combinations (e.g., for descriptors and qualifiers). All the blank nodes created initially were removed.

6 Conclusions

In the absence of an authoritative version of MeSH in RDF from the NLM, there have been several efforts over the past few years to make MeSH available for the Sematic Web. We identified six existing representations of MeSH in RDF and conducted a manual analysis of these representations. Based on the characteristics of these resources we compiled a list of desirable features for an authoritative representation of MeSH in RDF (completeness, usability, linkability, currency, availability and transparency). We implemented a prototype of an authoritative representation of MeSH in RDF that fulfills these criteria and illustrated its suitability on three use cases. Our prototype was influenced by our early baseline representation in RDF of all features present in the XML version of MeSH. However, we made substantial changes in order to improve usability and linkability. NLM intends to release an authoritative representation of MeSH in RDF in the Fall of 2014. We believe that the availability of such a resource will foster the adoption of MeSH in biomedical Semantic Web applications.

Acknowledgements

This work was supported by the Intramural Research Program of the NIH, National Library of Medicine (NLM). The authors would like to thank former NLM colleagues Ramez Gazzaoui and Genaro Hernandez, who contributed to an early prototype of MeSH in RDF in 2009, and Nancy Fallgren for sharing her insights on the BIBFRAME project. Thanks to the NLM Linked Data Infrastructure Working Group and to colleagues from the MeSH development team for their encouragement and support.

Abstract

The goal of this study was to compare the value of mammographic features and genetic variants for breast cancer risk prediction with Bayesian reasoning and information theory. We conducted a retrospective case-control study, collecting mammographic findings and high-frequency/low-penetrance genetic variants from an existing personalized medicine data repository. We trained and tested Bayesian networks for mammographic findings and genetic variants respectively. We found that mammographic findings had a higher discriminative ability than genetic variants for improving breast cancer risk prediction in terms of the area under the ROC curve. We compared the value of each mammographic feature and genetic variant for breast risk prediction in terms of mutual information, with and without consideration of interactions of those risk factors. We also identified the interactions between mammographic features and genetic variants in an attempt to prioritize mammographic features and genetic variants to efficiently predict the risk of breast cancer.

Introduction

Technology advances in genome-wide association studies (GWAS) and successes with cost reduction in genome-sequencing have engendered optimism that we have entered a new age of precision medicine[1], in which the risk of a breast cancer can be predicted on the basis of a person's genetic variants. More recently, however, the optimism of these studies has been tempered by disappointment and caution[2, 3]. Now it is widely agreed that phenotypic data, in concert with genetic variants will likely be necessary for advancing personalized breast cancer risk prediction. The availability of imaging findings acquired from mammography provides the opportunity to combine mammographic features and genetic variants to improve risk prediction[4, 5]; however, the comparative value that mammographic features and genetic variants provide for advancing risk prediction is unknown. The potential to quantify the value and prioritize phenotypic data (mammographic features) and genotypic data (germline genetic variants) for clinical decision-making presents an exciting opportunity to explore feature ranking algorithms for optimizing breast cancer risk prediction.

Mutual information analysis has been widely used to rank variables by quantifying the information that each variable provides for estimating the outcomes of interest [6, 7]. Prior studies have explored mutual information for genome-wide data analysis to discover association between single nucleotide polymorphisms (SNPs) and disease; however, few have considered interactions between risky SNPs[8]. Many believe that epistatic interactions of SNPs are important in determining susceptibility to breast cancer as well as disease mechanism[2, 9] . Hence, recent studies propose to utilize mutual information analysis for joint analysis of multiple SNPs that are potentially associated with breast disease[10]. Coincident to those studies, mutual information analysis has also been used to identify diagnostically important mammographic features. Most of these studies selected only the top-ranked features without considering interactions among features[11]. Recently investigators have used multidimensional mutual

information analysis to rank mammographic features by considering interactions when ranking for feature selection[12]. Overall, mutual information analysis has been successfully utilized to rank either SNPs or mammographic features for breast cancer risk estimation. However, to our knowledge, few studies have attempted to select the most important risk factors from a combination of mammographic features and genetic variants, and fewer have investigated interactions between mammographic features and genetic variants.

In this study, we aim to compare the values of mammographic features and SNPs for selecting the most informative risk factors in the diagnosis of breast cancer. We use mutual information analysis and Bayesian reasoning by considering interactions among risk factors to select the most valuable mammographic features and SNPs in breast cancer risk estimation.

Materials and Methods

The Marshfield Clinic Institutional Review Board approved the use of Marshfield Clinic's Personalized Medicine Research Project (PMRP) cohort in the research.

Subjects

The PMRP cohort, details of which have been previously published[13], was used in this study. To summarize, Marshfield Clinic patients residing in one of 19 ZIP code areas surrounding Marshfield, WI and aged 18 years or older, were invited to participate in PMRP. Written informed consent was obtained from each participant along with a blood sample from which DNA, plasma and serum were extracted and stored. Permission was given by each participant to link their electronic health record information to biological samples for use in the research.

We used PMRP to select subjects with an available DNA sample, a mammogram, a breast biopsy within 12 months after the mammogram from the Marshfield Clinic Data Warehouse. We employed a retrospective case-control study design. Cases were defined as women having a confirmed diagnosis of breast cancer obtained from the cancer registry, which includes either invasive breast cancer (ductal and lobular) or ductal carcinoma in situ. Controls were determined through the electronic medical records (and absence from the cancer registry) as never having had a breast cancer diagnosis. To construct case and control cohorts that were similar in age distribution, we employed an age matching strategy to ensure that the age of the matched control was within 5 years of the case.

Mammography Features

The American College of Radiology developed the Breast Imaging Reporting and Data System (BI-RADS) lexicon to standardize mammographic findings and recommendations[14]. The BI-RADS lexicon consists of a number of mammographic features, including the characteristics of masses and micro-calcifications, breast composition and other associated findings, which can be organized in a hierarchy (Figure 1). In Marshfield Clinic's electronic health record, mammographic findings including breast composition were described in BI-RADS lexicon and embedded in free text clinical reports, from which we used a parser to extract 46 mammographic features[15].

Genetic Variants

Our study focused on high-frequency/low-penetrance genetic variants that affect breast cancer risk as opposed to low frequency genetic variants with high penetrance (BRCA1 and BRCA2) or intermediate penetrance (CHEK-2). In clinic, individuals with BRCA1 and BRCA2 mutations demonstrating a high risk of breast cancer are managed with more intensive screening and have options for chemoprevention. Our study was designed for normal risk individuals, for which recommendation of screening and chemoprevention options are less clear. We included 22 genetic variants which have been identified by recent large-scale genome-wide association studies[4] (Table 1). The SNPs used in Gail model[16, 17] and Wacholder et al study[18] were included in our study. When we built the models

with the genetic variants, we coded each genetic variant as whether the subject carries the minor allele, rather than the specific genotype the subject carries.

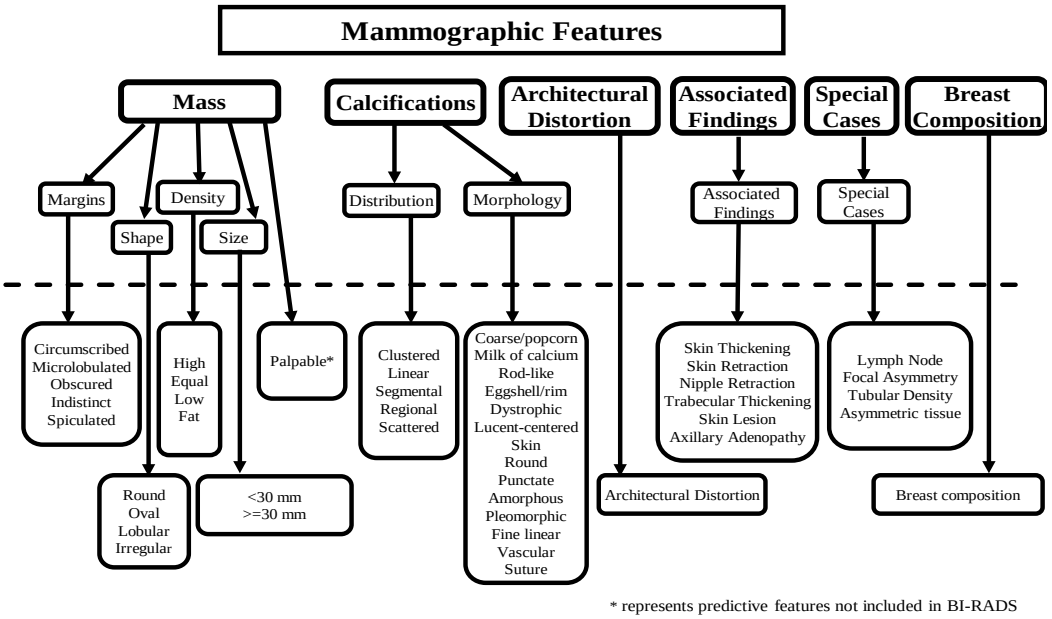

Figure 1. Mammographic features adopted from BI-RADS lexicon

Mutual Information

Originating from Shannon's information theory[7], mutual information (MI) of a variable v_1 with respect to the other variable v_2 is defined as the amount by which the uncertainty of v_1 is decreased with the knowledge that v_2 provides. The initial uncertainty of v_1 is quantified by entropy $H(v_1)$. The average uncertainty of v_1 given knowledge of v_2 is conditional entropy $H(v_1|v_2)$. The difference between initial entropy and conditional entropy represents therefore MI of v_1 with respect to v_2. MI is defined as follows:

$$\mathrm{MI}(v_1; v_2) = H(v_1) - H(v_1|v_2) = \sum_{v_2}\sum_{v_1} p(v_1, v_2) log \frac{p(v_1, v_2)}{p(v_1)p(v_2)}$$

where $p(v_1)$ and $p(v_2)$ are the marginal probability of v_1 and v_2, and $p(v_1, v_2)$ is their joint probability.

In the following context, we use $\mathrm{MI}(x_1; x_2)$ to denote the information value that one risk factor x_1 (either a mammographic feature or a SNP) provides for estimating the other risk factor x_2 to quantify the interaction between them. We use single-dimensional mutual information $\mathrm{SMI}(x; y)$ to denote the information that one risk factor x provides for estimating the outcome y (breast cancer).

$$\mathrm{SMI}(x; y) = H(x) - H(x|y) = \sum_{y}\sum_{x} p(x, y) log \frac{p(x, y)}{p(x)p(y)}$$

where x is one of risk factors and y is the outcome. SMI does not take into account interaction effects among risk factors.

We use multidimensional mutual information $\mathrm{MMI}(x; y)$ to denote the information that one risk factor x provides for estimating the outcome y when interaction with other risk factors is considered. We assess MMI by an algorithm that **m**inimizes **R**edundancy among risk factors while **M**aximizing **R**elevance to the outcome (mRMR)[19-22]. "Redundancy" is related to MI of risk factors with each other, and "relevance" is defined as SMI of risk factors with the outcome. Specifically, in this study, to use mRMR algorithm to rank most important risk factors, we choose the risk factor with the highest SMI as the most important one. We select subsequent important risk factors sequentially, such that each risk factor simultaneously maximizes its SMI and minimizes MI between the risk factor of interest and already selected risk factors. Specifically, we choose the next most important risk factor x_i, $i = 2, 3, 4, \cdots$, that maximizes

$$\mathrm{SMI}(x_i;\ y) - \frac{1}{i-1}\sum_{j<i} \mathrm{MI}(x_i; x_j)$$

where risk factor x_j is one of important risk factor selected ahead of x_i and y is the outcome.

Study Design and Statistical Analysis

To quantify the predictive performance of mammographic features and SNPs, we trained and tested Bayesian networks (BN) using a tree augmented naïve Bayes algorithm on all 46 mammographic features and 22 SNPs respectively in Weka (Weka, version 3.6.4; University of Waikato, Hamilton, New Zealand)[23]. We chose a BN as our prediction method since it has a clear semantic interpretation of model parameters[24]. We employed 10-fold cross-validation to help confirm the validity of predictions. We constructed a receiver operating characteristic (ROC) curve based on estimated probabilities from the BN, and obtained the area under the ROC curve (AUC) as a measure of overall predictive performance. We compared AUCs for 46 mammographic features and 22 SNPs by using the DeLong method[25], implemented in MATLAB software (MathWorks, Natick, MA). We used a P-value of 0.05 as the threshold for statistical significance testing to determine the difference between two AUC values.

We calculated SMI of each risk factor (either a mammographic feature or a SNP) with respect to the outcome, and ranked all risk factors according to SMI values. To evaluate the performance of SMI ranking approach, we first constructed risk factor sets by sequentially selecting the most informative risk factors, one by one, in order of SMI values. Then, using 10-fold cross-validation, we trained and tested BNs on the sets of sequentially selected risk factors. We created ROC curves based on estimated probabilities from the BNs, and obtained AUCs.

We then calculated MMI of each risk factor by using mRMR algorithm and ranked all risk factors based on those MMI values. Using a similar procedure of evaluating SMI rankings, we assessed the performance of MMI ranking approach. We first created risk factor sets with sequentially selected risk factors, one by one, in order of

MMI values and then trained BNs with those risk factor sets. We created ROC curves based on estimated probabilities from the BN, and obtained AUCs.

We also used "parsimony" to describe the performance of two ranking approaches. We define parsimony here as the smallest number of the risk factors needed to reach a performance level such that there is no significant difference of AUC as compared with the maximum AUC. The difference of parsimony between SMI and MMI describes the interaction effects among risk factors.

Results

We succeeded in identifying 373 cases and 395 controls, all European American. The age range for these subjects was 29 to 90 years of age (mean = 62, standard deviation = 12.8). Specifically, 3.12% subjects were less than 40 years old, 16.28% subjects were in between 40 and 49 years old, 27.34% subjects were in between 50 and 59, 22.92% subjects were in between 60 and 69, and 30.34% subjects were older than 69 years old.

Both mammographic features and SNPs demonstrated substantial capability of improving breast cancer risk prediction (Figure 2). We found that AUC value from BN trained and tested with mammographic features was significantly higher than that without mammographic features (SNPs alone) (0.736 vs. 0.581, P-value < 0.001). The difference represents the value provided from mammographic features for breast cancer risk estimation. We also found that AUC value from BN trained and tested with SNPs improved significantly compared with that without SNPs (mammographic features alone) (0.736 vs. 0.704, P-value = 0.012). Furthermore, the risk estimation using only mammographic features was superior to using only SNPs (0.704 vs. 0.581, P-value < 0.001). Notably, one mammographic feature (spiculated mass margins) could achieve a similar predictive performance as all 22 SNPs in terms of AUC (0.590 vs. 0.581, P-value = 0.765).

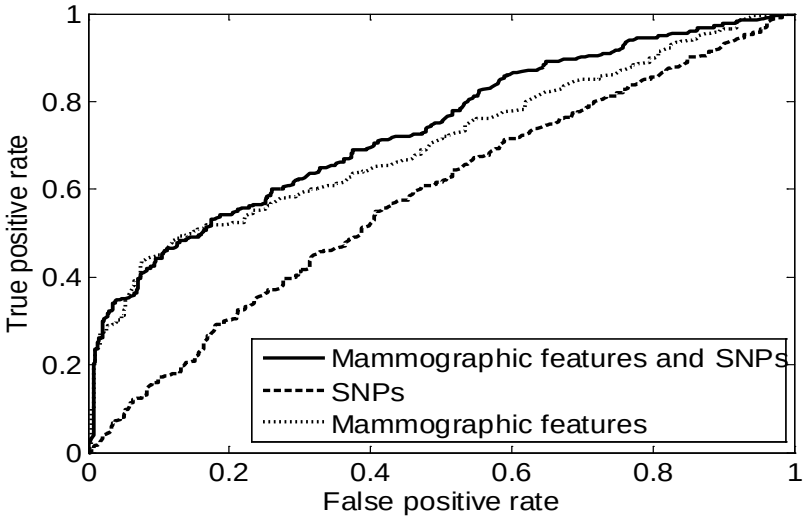

Figure 2. ROC curves for mammographic features, SNPs, and a combination of mammographic features and SNPs.

Both SMI and MMI approaches were able to prioritize breast cancer risk factors. However, in terms of parsimony, the MMI approach outperformed SMI. Specifically, when we calculated AUC values to evaluate SMI ranking results, we observed that AUC values increased as more features were included (solid curve with triangle data points in Figure 3). Parsimony for the SMI approach (the number of features needed to reach a non-significant difference between SMI AUC and maximum AUC—0.733 vs. 0.752, P-value = 0.053) was twelve features. For MMI ranking results, we observed that correspondent AUC values also increased as additional features were

included (dashed curve with cycle data points in Figure 3). Parsimony for the MMI approach (the number of features needed to reach a non-significant difference between MMI AUC and maximum AUC—0.733 vs. 0.752, P-value = 0.109) was eight. Both parsimony sets included mammographic features and SNPs (Table 2).

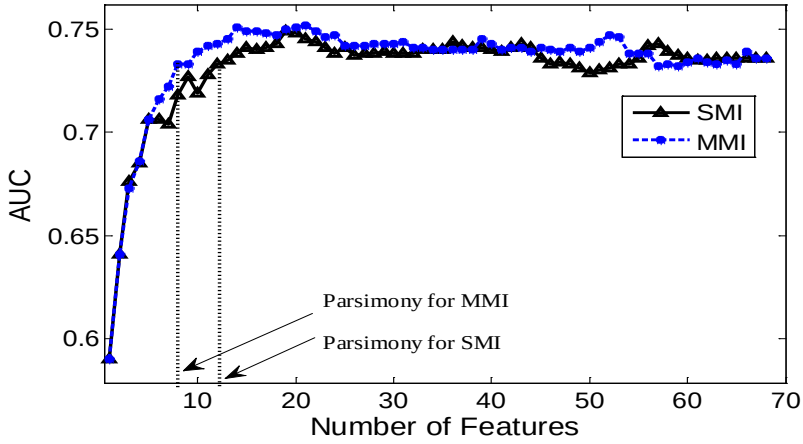

Figure 3. AUC changes with the number of selected features. Solid curve, SMI; Dashed curve, MMI.

Table 2. Ranking results based on SMI and MMI (partial)

Variables	SMI ranking	MMI ranking
Spiculated mass margins	1*	1*

rs2107425	14	11
…….	……	……
* risk factors included in parsimony sets		

The rankings of mammographic features and SNPs were different for SMI and MMI approaches (Table 2). The difference demonstrated the effects of associations of mammographic feature-mammographic feature, SNP-

SNP, and mammographic feature-SNP. We found that the association of feature-SNP was relatively weak compared with the associations of feature-feature and SNP-SNP. For the three most informative mammographic features in breast cancer prediction, spiculated mass margin, irregular mass shape, and mass size, we observed that other mammographic features instead of SNPs were strongly associated with them when we used a 0.01 threshold in MI analysis (Table 3). Similarly, for the three most informative SNPs in breast cancer prediction, rs13387042, rs8051542, and rs10941679, we found that other SNPs instead of mammographic features were strongly associated them (Table 4). For all mammographic features and SNPs, pleomorphic classification-rs1045485/rs17468277 was the only mammographic feature-SNP pair demonstrating strong association.

Discussion

Both mammographic features and SNPs are important in breast cancer risk prediction. Our study shows that mammographic features can significantly improve breast cancer diagnosis over genetic variants. It is unlikely that germline genetic analysis alone will be sufficient to fulfill the promise of precision medicine in the arena of breast cancer risk prediction[26]. The results from this study advocate greater use of phenotypic data such as mammographic findings to predict breast cancer risk. Concurrently, our study shows that genetic variants can significantly improve breast cancer diagnosis over mammographic findings. Traditional oncologic risk estimation based on tissue analysis may be augmented by genetic variants. GWAS have identified a series of genetic variants underlying breast disease, which would greatly facilitate personalized cancer diagnosis. However, there are no standards for evidence-based genetic biomarker development and some genetics studies have yielded contradictory results[27]. There are many questions to be answered and barriers to be overcome before genetics can be most effectively used in the clinics to benefit patients. In summary, for maximal accuracy of next-generation breast cancer

risk prediction models, genetic variants and clinical data should be combined and tuned for better predictive performance.

Computational and experimental methods to detect interactions of risk factors are promising for the future of breast cancer screening and diagnosis. We find that multidimensional mutual information addresses the issue of interaction of risk factors and may have the potential to assist physicians in prioritizing predictive variables in order to select the most parsimonious set of mammographic features and genetic variants with the highest predictive ability. There are many risk factors potentially used to estimate breast cancer risk. SMI analysis demonstrated that twelve risk variables were needed to reach an AUC that wasn't significantly different from the maximum AUC. Performance analysis based on MMI reduced the number of important variables to eight. Assessing additional variables beyond these most important ones does not improve risk prediction accuracy. This suggestion of using a smaller set of important mammographic features and SNPs for breast cancer diagnosis may help improve breast cancer screening and diagnosis workflow in the future.

Mutual information approaches (SMI and MMI) have the capability of determining the most informative genetic variants for breast cancer diagnosis. Both SMI and MMI approaches demonstrated that rs13387042, rs8051542, and rs1094169 were the three most important risk-conferring factors in 22 SNPs for the development of breast cancer (Table 2). This result is in line with some of previous findings that these three SNPs are strongly associated with breast cancer[27-29]. In addition, both approaches showed that rs13387042 was the most important risk factor in 22 SNPs, which is consistent with our knowledge about its significance in breast cancer risk estimation. This SNP has been included in Gail model[16, 17] and Wacholder analysis[18] for breast cancer risk prediction. Overall, our results indicate that mutual information analysis may be an effective approach to evaluate the association between SNPs and breast cancer.

Recently the analysis of associations between imaging features and somatic mutations/molecular markers has attracted much interest in the imaging and biomarker community. This trend has led to widespread radiogenomic studies in the hopes of better diagnostic accuracy and more precise prognostication[30-32]. The results from our radiogenomic analysis reveal that some association between mammographic features and germline SNPs exists though their magnitude is less than mammographic feature-mammographic features associations or SNP-SNP associations. We found that pleomorphic classification-rs1045485/rs17468277 was the only feature-SNP pair demonstrating strong association (mutual information > 0.01), which is in concert with previous studies[4]. This sporadic association may be caused by several factors. First, GWAS has analyzed hundreds of thousands of SNPs to determine whether they are associated with breast cancer. Our study has used a very limited set of SNPs. Including a larger set of SNPs is crucial for the success of radiogenomic analysis. Second, our study considers association between one SNP and one mammographic feature only. More complex interactions of mammographic feature-mammographic feature and SNP-SNP will likely be a fruitful area of future research. Third, other imaging modality like MRI has proven to be more sensitive than mammography[31] or convey functional information (rather than anatomic data). It would be interesting to induce imaging features collected from MRI into our future radiogenomic studies.

Limitations and Future Work

There are several limitations to our study. First, the sample size is small compared with large-scale genome-wide association studies, due to the inherent difficulty of collecting a rich multi-modality dataset. Second, our study focused on discussion of predictive accuracy associated with risk factors but did not consider benefit and cost related to the decision. We plan to extend our study in this direction soon since cost-effectiveness analysis allows physicians and policymakers to compare the health gains that various decision of choosing the most important mammographic features and genetic variants can achieve. Third, our study used Bayesian networks to assess ranking results of mutual information analysis. A possible line of future research is to employ other prediction

algorithms such as logistic regression, artificial neural network, or support vector machine for validating our results. Finally, we used AUC to measure the performance of our Bayesian networks. The AUC evaluates the performance of a prediction method over the full range of possible threshold levels. In practice, however, only a limited range or a single optimal threshold level may be of interest clinically. We plan to extend our study by determining the optimal threshold level to measure the predictive performance of our Bayesian networks in terms of sensitivity and specificity.

Conclusion

Our study represents one of the first explorations of breast cancer risk prediction using genetic polymorphisms in combination with mammographic features. We find that genetic risk factors improve risk prediction to a statistically significant degree, which raises the possibility that stratification based on these risk factors may provide an opportunity to personalize care in clinical practice. This work confirms that disease prediction, which is narrowly focused on one data type (e.g. genomics) may miss opportunities for improved performance offered by incorporation of phenotypic data (e.g. mammographic features). We demonstrate that genetic risk factors can be combined and tuned with clinical imaging findings for better predictive performance. Moreover, considering interactions among risk factors, MMI outperforms SMI in determining the smallest set of informative risk factors. In applications where addition of risk factors incurs additional time or monetary cost, MMI may help reduce the cost of diagnostic testing. Encouraged by these promising results, we plan to further explore genotype/phenotype associations to shed light on disease processes that may, in the future, improve diagnosis and treatment.

Information is in the eye of the beholder: Seeking information on the MMR vaccine through an Internet search engine

Elad Yom-Tov, PhD[1], Luis Fernandez-Luque, PhD Candidate[2, 3]
[1]Microsoft Research, Herzeliya, Israel; [2]UiT - The Arctic University of Norway, Computer Science Department Tromso, Norway, [3] Norut, Tromso, Norway

Abstract

Vaccination campaigns are one of the most important and successful public health programs ever undertaken. People who want to learn about vaccines in order to make an informed decision on whether to vaccinate are faced with a wealth of information on the Internet, both for and against vaccinations. In this paper we develop an automated way to score Internet search queries and web pages as to the likelihood that a person making these queries or reading those pages would decide to vaccinate. We apply this method to data from a major Internet search engine, while people seek information about the Measles, Mumps and Rubella (MMR) vaccine. We show that our method is accurate, and use it to learn about the information acquisition process of people. Our results show that people who are pro-vaccination as well as people who are anti-vaccination seek similar information, but browsing this information has differing effect on their future browsing. These findings demonstrate the need for health authorities to tailor their information according to the current stance of users.

Introduction

Vaccination programs are one of the greatest public health successes in history. Scourges such as smallpox and poliomyelitis have been completely eradicated or are confined to relatively small areas of the globe. In order to achieve the maximal potential of vaccination campaigns, a large percentage of the population needs to be vaccinated, so as to achieve "herd immunity" which significantly reduces the likelihood of epidemic outbreaks. Sadly, in parallel to vaccination programs, there is a worldwide trend towards a hesitancy to vaccinate, catalyzed by the activism of anti-vaccination groups[1].

The presence of an anti-vaccination movement in a country has been found to correlate with lower vaccination rates[2]. Studies have tracked the presence and importance of those movements in the online sphere, especially social media[3]. This is especially pertinent as nowadays the debate about vaccination is prominent on the Internet[4]. Several studies examined online data sets for the tracking and characterizing the online anti-vaccination movement. For example, Salathe et al.[5] studied the sentiment of people on the social network Twitter with regards to influenza vaccination in the USA. The Vaccine Confidence project is tracking online media to index the sureness of people in vaccine across different countries[6]. Together, these studies show that anti-vaccination content is prevalent and may have a detrimental effect on vaccination rates.

People who wish to make an informed decision on whether or not to vaccinate themselves or their children can therefore find information both supportive of vaccination and opposed to it. Understanding the information seeking process of people as they learn about vaccinations is crucial in order to address their concerns and provide them with convincing information on the importance of vaccination. Many factors affect the information seeking process, and include available sources of information, prior beliefs and understanding, and current news. It has been found that the anti-vaccination misconceptions vary across countries and even across different vaccinations[7]. In the USA, a study found that parents refusing to vaccinate their children were doing so based on information obtained by word-of-mouth, for religious or philosophical reasons, because of low perceived risk of diseases and due to anti-government sentiment[8].

McRee et al.[9] found in a study in the USA that nearly 70% of the parents who had questions concerning vaccinating their child against the Human Papilloma Virus (HPV) searched for information on the Internet. Although that study found that trust of healthcare professionals was high, many people supplement information from these professionals with information sought online.

One of the most common activities online is using a search engine to find information[9]. Internet search engine queries have been shown to reflect both the activities of people in the virtual world[10], as well as those in the physical one. For example, Ofran et al.[11] found a high correlation between the number of searches for specific types of cancer and their

prevalence in the population. Similarly, Yom-Tov and Gabrilovich[12] showed a high correlation exists between the number of prescriptions sold for a drug and the number of people who search for it. Because of this, Internet search engines have been used for learning about medicine and health in a variety of areas. These including knowledge acquisition by cancer patients and their family members[11], obesity and its correlated behaviors[13], and the side effects of medical drugs[12].

Internet search data has also been used to learn about public health, sometimes by measuring effects that are difficult to measure in the physical world. As such, prevalence of influenza was estimated by several researchers[14-16]. More recently, the effect of media reporting of celebrities who are suspected to be suffering from eating disorders on the development of anorexia was studied in Yom-Tov and boyd[17].

In this study we focus on the information acquisition process vis-a-vis vaccines, as evident from the searches of people conducted on a major Internet search engine. To the best of our knowledge there are no studies which examined how people utilize Internet search engines to garner information on vaccination.

Previous beliefs predispose people to a pro- or anti-vaccination stance even before they begin their information acquisition process. This predisposition can lead people who seek information on vaccination to selective exposure, that is, the well-documented tendency of people to people seek information which affirms their viewpoint and avoid information which challenges it[18,19]. However, recent work has shown that, at least in the political domain, provided the information is chosen appropriately, it is possible to cause people to overcome selective exposure and read views opposing to theirs[20]. Our goal is to validate whether selective exposure occurs when learning about vaccination, and if so, to be able in future to use similar approaches to those developed for the political domain in order to better inform parents on the importance and necessity of vaccinations.

Our findings show that when people acquire information about the MMR vaccine they do so with preconceived notions that bias their search for information. Selective exposure occurs both in the information that people choose to seek and in the way they process it. This suggests that providers of information on vaccines need to tailor their content according to the predicted stance of the user.

Methods

The methodology in this work comprises of several stages. First, we devised a method for scoring search engine queries to the attitude of the users who made them towards vaccines. We then applied this score to anonymized data from the Bing search engine. These data were aggregated with vaccine uptake information from CDC and analyzed to show both the impact of individual queries and the temporal progression of users as evident from their queries. In addition, we performed a novel validation of our scoring method using an online advertisement campaign.

Search engine query log data

We extracted all queries to the Bing search engine made by users in the USA during 6 months starting March 2013 which included keywords related to the MMR vaccine. The list of keywords included the vaccine name (MMR or MMRV), as well as the trade names of the vaccine: Priorix, Tresivac, and Trimovax. This resulted in 252,526 queries from approximately 115,714 users. Of these, 9,985 users made five or more MMR-related queries. Data on each query comprised of an anonymized user identifier, time, query text, zip code of the user, the pages displayed to the user as a response to the query, and of these, the pages clicked by users. In order to maintain user privacy, data were anonymized before the investigators had access to them. They were then aggregated prior to analysis, and no individual-level user datum was examined. Thus, all the searches of each individual can be identified, but they cannot be attributed to a specific individual.

Our analysis throughout this paper is based on a scoring of queries made by users and the webpages displayed to them in response to these queries. This scoring is intended to reflect the likelihood that a person making these queries or reading these documents will vaccinate their child against MMR. Broadly, we label a person with a low probability to vaccinate as anti-vaccination, and a person with a high probability to vaccinate as pro-vaccination.

Vaccine attitude scores

We score search engine queries as to the likelihood that a person who made them would be receptive towards vaccination. We refer to these scores as the **Vaccine Attitude Score** (VAS), and in this section detail its calculation.

Our scoring is based on CDC data[1] on vaccination rates (percentage of children vaccinated) in US states and specific urban centers. Each query and page (URL) was scored according to the average of the vaccination rate in the areas from which users to whom the pages were displayed came from. Let z_i be the vaccination rate at the zip code from which the *i*-th query was issued. We score each query and each page d_j displayed in response to this query such that:

$$S_{q_i} = \frac{1}{N} \sum_{i=1}^{N} z_i$$

and

$$S_{d_j} = \frac{1}{N} \sum_{i=1}^{N} z_i$$

Clearly, $0 \leq s_{d_j} \leq 100$. Such a scoring method is akin to the methods used in Yom-Tov et al.[20] to elicit the political intent of queries, using the voting patterns in each zip code. We refer to this scoring method as the VAS. A high VAS implies a higher likelihood that a person issuing the query or visiting the web page will vaccinate. We validate VAS and its use for scoring vaccine-related queries and web pages in the Results, through two separate means.

Results

Assessing the accuracy of VAS for queries and pages

A described in the Methods Section, each query and URL were scored according to the average vaccination rates at the area where people who made these queries reside, so as to obtain an estimate of the likelihood that people reading these pages will vaccinate against MMR. This is similar to the method used in Yom-Tov et al.[20] to score political queries. In this section we validate whether this scoring method, which we refer to as VAS, is accurate in the context of vaccine-related queries scored according to the vaccination rates.

Here we employ two methods for validation. First, we use a novel method utilizing online advertising to capture whether queries are posted by people who are pro- or anti-vaccination. Second, we use human assessors to classify web pages according to whether they perceive the information in them as leading to a higher chance of vaccination.

Estimation of queries using online advertisements

We selected the 10 queries with the highest VAS values, computed according to the methods described in the Methods Section, as well as the 10 queries with the lowest VAS values. For each of these, we placed advertisements on the Bing search engine, such that when people queried for one of these 20 queries, one of two advertisements would be shown at the right hand side of the search results page. The advertisements were shown with equal probability, and the Bing ads system showed them when the price we were willing to pay (our bid) for placing these ads was greater than that of any other advertisement placed for these search terms. In some cases additional, competing ads were shown above or below the advertisements we placed.

Both advertisements were similar in their title ("MMR vaccine"), shape, colors, and the link to which they referred. One advertisement, shown in Figure 1, stated in its text "Do you want to learn about the importance of this vaccine?",

[1] http://www.cdc.gov/nchs/nis/data_files_teen.htm

while the other substituted the word "importance" with the word "dangers". In both cases, clicking the advertisement led people to the CDC page on the MMR vaccine.

We hypothesized that the first advertisement would appeal to people who were pro-vaccination, while the second advertisement would appeal more to people who were anti-vaccination. Thus, we expect that ads on the dangers of the vaccine would be clicked more when they appear next to results for queries made by people with an anti-vaccination stance, and that ads on the importance of the vaccine would be clicked more when they appear next to results for queries made by pro-vaccination people.

The advertisements were shown a total of 5476 times over a period of 15 days. Table 1 shows the clickthrough rate (CTR) for each query and advertisement combination. CTR is the percentage of advertisements which were clicked out of all the advertisements shown. As the table shows, advertisements mentioning the importance of the vaccine tended to be clicked 2.55 times more by people who made queries with high VAS, compared to those by people who made queries with low VAS. Similarly, advertisements which mentioned the dangers of the vaccine were 1.19 times more likely to be clicked by people who made queries with low VAS, compared to those by people who made queries with high VAS.

Thus, we conclude that our results support our hypothesis, that pro- (anti-) vaccination people are more likely to click pro- (anti-) vaccination advertisements, and, furthermore, that our method for scoring queries is accurate in that it assigns high VAS values to queries made more by pro-vaccination people, and vice versa.

Estimation of page VAS using human assessment

Three human assessors were tasked with classifying the 20 pages with the highest page VAS values and the 20 pages with the lowest pages VAS values. Each assessor was asked to label each pages according to the question "Does this page lead to a more pro-vaccination stance?". Possible answers were "yes", "no", or "undecided".

The free marginal Kappa[21] for the three annotators was 0.312, indicating a medium-level agreement. Limiting our analysis to 20 pages which had a standard deviation across users smaller than 2%, because of the need to focus on pages which are accessed by a relatively homogenous population, we find that for pages categorized by a majority of labelers as leading to a more pro-vaccination stance the average VAS was only slightly higher at 72.7, compared to 72.1 (not statistically significant). This minor difference can be for one of two main reasons: Either the page VAS given according to vaccination rates is unrepresentative, or else, the page VAS should be evaluated in the context of how it influenced the next page read.

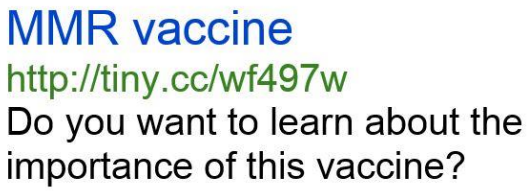

Figure 1. Pro-vaccination ad placed next to Bing searches

	Advertisement	
	Anti	Pro
Low VAS values	0.556	0.468
High VAS values	0.472	1.197

Table 1. Clickthrough rate for pro-vaccination and anti-vaccination advertisements, as a function of query VAS values.

To distinguish between the two, we scored each consecutive pair of pages read by a user, denoted by d_t and d_{t+1} according to the differences in VAS values between them, $s_t = d_{t+1} - d_t$. The average page VAS for those pages labeled as leading to a more pro-vaccination stance was 0.52, compared to a VAS of 0.05 for pages labeled as not leading to a more pro-vaccination stance. Thus, we hypothesize that the latter assumption, that page VAS values should be evaluated according to how they modify a user's reading habits, is the correct one, and that our labeling thus evaluated is a useful way to score pages as to the propensity of users to vaccinate against MMR.

Queries and domains with the highest and lowest VAS

Table 2 shows the list of queries with the highest and lowest VAS in our data. Several interesting observations can be seen from this table. First, both types of queries discuss similar issues, but do so from different viewpoints. For example, the (discredited) link between MMR and autism is addressed as a given in queries with the lowest VAS ("MRR vaccine linked to autism"), but as a possibility in queries with the highest VAS ("link to autism"). Similarly, an Italian court case that suggested that MMR caused autism is searched for in a factual manner in queries with high VAS, whereas people making the queries with a low VAS search for information validating the link ("courts confirm mmr vaccine causes autism"). This suggests that at least some of the people who search for information on vaccines have a preconceived notion of whether or not they intend to vaccinate their children, and are only seeking affirmation of their position. We address this in more detail below.

Among the pages with the lowest VAS, two pages are from CDC, one from Wikipedia, and the remaining are from social media and medical information websites. Pages with the highest VAS include 3 pages from CDC, one from the World Health Organization (WHO), and the remaining are from social media and medical information websites.

In order to obtain a more robust estimation of information sources, we repeated the analysis at the website level, using all websites that had at least 10 scored pages. The score for a website was the average VAS of pages on it. Here, the lowest scored websites included authoritative sources (BMJ, Mayo Clinic, *vaccineinformation.org,* as well as several anti-vaccination websites (*vaccinetruth.org*, *vaccineinjuryhelpcenter.com*), parenting websites (*momtastic.com*), and pharma websites (*merckvaccines.com*). The highest scored websites included parent websites (*mamapedia.com*, *netmums.com*), anti-vaccination websites (*mercola.com*, *vran.org*), government sites (*ny.gov*), and medical websites (*pediatriconcall.com*). Thus, both pro-vaccination and anti-vaccination people read information from similar sources (including government organizations), but, apparently, interpret them differently.

Lowest VAS queries	Highest VAS queries
mmr vaccine linked to autism	mmr vis
side effects of mmr vaccine in adults	when do kids get mmr vaccine
ingredients in mmr vaccine	rash from mmr vaccine
mmr vaccine lot numbers	fever after mmr vaccine
cdc mmr	mmr vaccine administration for adults
mmr vaccine court case	mmr vaccine link to autism
adult mmr vaccine schedule	how to give mmr vaccine
courts confirm mmr vaccine causes autism	mmr vaccine italian court
rash after mmr vaccine photos	mmr vaccine and ppd
mmr vaccination side effects of mmr	vaccine for toddlers

Table 2. Queries with the highest and lowest VAS, according to the vaccination rates in askers geographies.

Modeling the information acquisition

Our goal is to understand what drives a user to read more pro- (or anti-) vaccination information. Therefore, we estimate the contribution of a specific page on the likelihood that a user will read pages with a higher or lower VAS, by modeling the transition of users between pages as a chain of transitions. Let the state of a user at time t_i (i=1,2,...,M) be represented by the VAS of the current page, s_{d_i}, the VAS of vaccine-related pages they read so far, $\sum_{j=1}^{i-1} s_{d_j}$, and the a-priory score of the user, according to the vaccination rate at their locale. The effect of the current page is measured by predicting difference between the VAS of the next page that the user will read and the current page VAS.

The results of a rank regression model, using 14,031 transitions, are shown in Table 3. The table shows that, taken individually, the current page VAS and the average page VAS of past reading have the highest influence on the VAS of the next page. Interestingly, both have a negative effect, that is, the higher the current VAS, the more likely it is to lead to pages with a lower VAS than the current one. This is, possibly, because of interactions between the scores up to time t_i and the score at time t_i. Therefore, model 4 uses all three attributes. Here we find that the R^2 of this model is only slightly greater than that of the model which uses only the current page. However, past reading and user scores contribute to a higher VAS of the next page. The implication of the negative coefficient for page VAS is that many pages are correlated with users reading information associated with a lower vaccination rate. This is an alarming finding, since it suggests that much of the online content on vaccination leads people to read more harmful content.

Since the current page VAS is most strongly correlated with the difference to the next page VAS, we attempt to estimate what in the language of the current page leads to a higher or lower VAS. To do so, we first remove the effect of past reading and user score, by building a rank regression model between these two factors and the difference in next page and current page VAS. Then, we represented each document through its vector space model[22] of words and lexical affinities[23], keeping words that appeared in at least 200 documents, but in no more than a quarter of the documents. We modeled the relationship between the words in the documents and the residual difference using a linear model, constructed using a linear Support Vector Machine (SVM) classifier (with the LibSVM implementation[24], using default settings).

Model number	Variable	Regression coefficient	Model R^2	p-value
1	Page VAS	-0.532	0.283	$<10^{-5}$
2	Past read	-0.387	0.150	$<10^{-5}$
3	User score	0.013	10^{-4}	0.12
4	Page VAS	-0.59	0.297	$<10^{-5}$
	Past read	0.06		$<10^{-5}$
	User score	0.11		$<10^{-5}$

Table 3. Rank regression models of user transitions. Page VAS is the score of the current page read. Past read is the average VAS of all page VASs up to the current time. User score is the vaccination rate at the users' locale.

The 20 words most likely to lead to a higher page VAS are (categorized by the authors, in parenthesis are explanations of the word):

1. Health authorities: guidelines, provider
2. Adverse effect: respiratory, experience (as in "may experience a rash"), avoid (women should avoid becoming pregnant within a month of vaccination), develop
3. Benefits of the vaccination: diphtheria (protection against)
4. Others: answer, lead, review (literature review), personal, scientific, USA, between vaccine, prior, viruses, syndrome, past, started, increased

The 20 words most likely to lead to a lower page VAS are (in descending order of importance, in parenthesis are explanations of the word):

1. Health authorities: control prevention, department, professional, FDA
2. Autism-related: diagnosis (autism diagnosis)
3. Adverse effect: meningitis, swelling, separate (vaccine given in separate parts, rather than all 3 components)
4. Benefits of the vaccination: benefits, pertussis (protection against)
5. Others: issue, activities, problem, means, December, recently, effect, Facebook, put, individual

Thus, both kinds of pages deal with similar topics, but pages leading to lower VAS emphasize adverse effects (and rumored effects) over the more mild symptoms usually experienced.

Differing understanding of similar information

The previous sections suggested that information on the current page and past user reading were most predictive of future reading, and that people who are opposed to vaccination, as well as those who were pro-vaccination read similar information. In this section, we attempt to directly quantify this finding. The null hypothesis is that information on a given page should cause a similar influence on people with differing views, since the information displayed on a page is identical, regardless of a persons' view.

We analyzed the sequence of clicks of each user on pages related to the MMR vaccine, and specifically concentrated on pages that were two or more pages after the beginning of a users' sequence, and at least two pages before it ended. This was done so that the average browsing VAS of a user could be computed both before and after the current click. However, this limited our analysis to 2941 page views, by 979 people who clicked on at least 5 pages.

Users were divided according to whether the average VASs of the pages they clicked on until the current page were above or below the median page VASs. Only 33% of pages were read by people of both groups. This means that people are only 33% likely to read opposing information, and though it is a low percentage, it is higher than that observed for political opinions, which is approximately 20%[20].

Focusing on 108 pages which were read by at least two people from both groups, we measured the fraction of people from each group that read pages with a higher VAS after reading the current page. The Spearman correlation between the fraction of people from each group that read pages with a higher VAS is ρ=-0.004, and not statistically significant. Thus, pages have dissimilar effects on people in the two groups. This means that our null hypothesis is refuted, in that if a page contains information that should lead people to a more positive view of vaccination, the likelihood of reading more positive information differs greatly between people who read pages with lower VASs, compared to those who read higher VASs.

In 78% of pages, the effect was more positive on people who had an average VAS below the median, than on people who had a VAS above it. The association between the page VAS itself and whether it had a bigger effect on one group

over the other is not statistically significant (ranksum test). This implies that, surprisingly, the majority of pages have a more positive effect on people who were previously under the median VAS.

Transitions between VAS quantiles

Our final analysis is concerned with the likelihood of transitioning between page VASs. All page VASs were divided into five quantiles, and the probability of the quantile of the next clicked page given the quantile of the current page was computed. The results are shown in Figure 2. First, as this figure shows, self-loops, indicating that the next page is within the same quantile, are the most common. The average probability of a self-loop is 0.701 (s.d. 0.075). Some of this is due to the coarse division into only five quantiles. However, even when dividing the pages into 20 quantiles, the average probability of a self-loop is 0.607 (s.d. 0.079). Thus, most transitions are to pages with similar VASs.

Figure 2 also shows that transitions are more likely towards quantile 3 than towards quantiles 1 and 5. Indeed, a random walk with restarts[25] (using a random restart probability of λ=0.15) finds that the most likely stable quantile is quantile number 3, with a probability of 0.404, states 2 and 4 have a stationary probability of 0.181 and 0.192, respectively, and stages 1 and 5 have a stationary probability of 0.108 and 0.114, respectively. Therefore, those people who do transition between quantiles are likely to end their search process in pages with VASs in the middle range, indicating that they did not accept extreme views, either towards vaccination or against it.

Discussion

Vaccinations are most effective when the overwhelming majority of the population receives them. Since few countries force citizens to vaccinate, it is important to provide accurate and convincing information to people so as to encourage vaccination. This is a pressing issue especially in the face of anti-vaccination information prevalent on the Internet, which has been linked to a decline in vaccination rates[2].

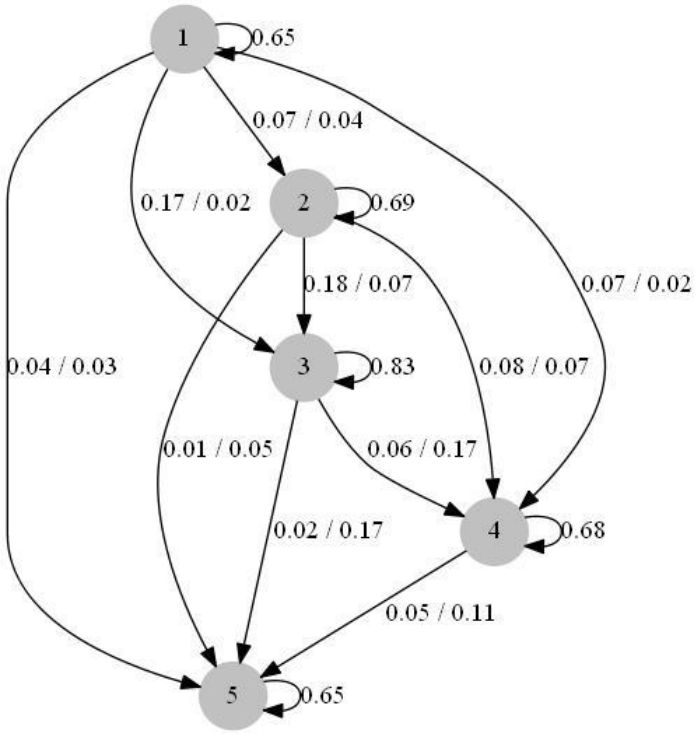

Figure 2. Probability of transition between page VAS quantiles. The left number of each edge represents the probability in the direction of the arrow and the right number the probability in the reverse. Lower quantiles imply lower probability to vaccinate.

In this paper we first developed and validated a way to score queries made to an Internet search engine, and the pages clicked on by users, as to the likelihood that they will be read by people with a pro- or anti-vaccination stance. We used a novel method based on online advertisements to validate our scoring. Our results indicate that our scoring method is useful in identifying such queries, in that people who are pro-vaccination, according to the query VAS value, are significantly more likely to click on advertisements which purport to provide information on the advantages of vaccines, and vice versa. This means that the proposed scoring methods can be used to learn about the information acquisition process, through the observation of sequential page VASs.

When people search for information on the MMR vaccine, their queries reveal their current bias towards vaccines. This represents a problem for pro-vaccination information providers, because their information may not be returned as a result to anti-vaccination queries, and thus pro-vaccination information will not be shown to those people. One possible solution to this problem is to create several types of information, each geared towards people with different attitudes towards vaccination.

Interestingly, though past reading and the information people receive from a web page have statistically significant correlations with future reading, depending on their past reading, people may interpret the same pages differently. Thus, mainstream medical sites feature prominently in the reading of people with an anti-vaccination stance, and the same pages have unequal effects on people of differing stances towards vaccination.

The findings our study have important implications for health authorities, since the Internet is gradually becoming a prominent channel for health education. Firstly, battling the online health misinformation by creating more content is very likely to be suboptimal. The problem it is not the lack of online informative resources about vaccination, but how to design informative resources that are found by those seeking information, whether pro- or anti-vaccination, and providing the most appropriate information for each. Our study provides insights on how to design online information about vaccination. Simple strategies can help, including the usage, within the websites (and their metadata) a vocabulary commonly used by those with anti-vaccination stances. However, further research is required to better understand the reasons for anti-vaccination decisions.

Another approach could be the use of query data for personalizing the health websites. For example, our scores about vaccination stance from search queries can be used to adapt a website about vaccination to provide information which depends on the stance of the visitor. Thus, instead of serving the same content to every person, health providers could offer several versions of their content, each matched to the language and bias of individual users.

Finally, we note that the findings of this study can be further applied to tackle misinformation which has been described by the World Economic Forum as one of the three major threats of the modern hyper-connected society[26].

Abstract

Sudden Unexpected Death in Epilepsy (SUDEP) is the leading mode of epilepsy-related death and is most common in patients with intractable, frequent, and continuing seizures. A statistically significant cohort of patients for SUDEP study requires meticulous, prospective follow up of a large population that is at an elevated risk, best represented by the Epilepsy Monitoring Unit (EMU) patient population. Multiple EMUs need to collaborate, share data for building a larger cohort of potential SUDEP patient using a state-of-the-art informatics infrastructure. To address the challenges of data integration and data access from multiple EMUs, we developed the Multi-Modality Epilepsy Data Capture and Integration System (MEDCIS) that combines retrospective clinical free text processing using NLP, prospective structured data capture using an ontology-driven interface, interfaces for cohort search and signal visualization, all in a single integrated environment. A dedicated Epilepsy and Seizure Ontology (EpSO) has been used to streamline the user interfaces, enhance its usability, and enable mappings across distributed databases so that federated queries can be executed. MEDCIS contained 936 patient data sets from the EMUs of University Hospitals Case Medical Center (UH CMC) in Cleveland and Northwestern Memorial Hospital (NMH) in Chicago. Patients from UH CMC and NMH were stored in different databases and then federated through MEDCIS using EpSO and our mapping module. More than 77GB of multi-modal signal data were processed using the Cloudwave pipeline and made available for rendering through the web-interface. About 74% of the 40 open clinical questions of interest were answerable accurately using the EpSO-driven VISual AGregagator and Explorer (VISAGE) interface. Questions not directly answerable were either due to their inherent computational complexity, the unavailability of primary information, or the scope of concept that has been formulated in the existing EpSO terminology system.

Introduction

Epilepsy is the most common serious neurological disorder, affecting 65 million persons worldwide; 150,000 new cases of epilepsy are diagnosed in the United States each year [1]. A third of epilepsy patients fail medical treatment and continue to have seizures [2, 3]. Sudden Unexpected Death in Epilepsy (SUDEP) is the leading mode of epilepsy-related death and is most common in patients with intractable, frequent, and continuing seizures [4]. SUDEP is characterized as "sudden, unexpected, witnessed or unwitnessed, non-traumatic and non-drowning death in an individual with epilepsy, with or without evidence for a seizure and excluding documented status epilepticus where postmortem examination does not reveal a cause for death" [5, 6]. Despite an increasing focus on SUDEP research and its inclusion as an NINDS Area III Epilepsy Research Benchmark priority [4, 7], limited progress has been made in characterizing SUDEP risk factors and mechanisms that lead to death. Effective prevention or treatment approaches are unavailable at present [8, 9].

The 2010 Institute of Medicine (IOM) report, "Elements of an Integrated National Strategy to Accelerate Research and Product Development for Rare Diseases," recommends a national strategy that "shares research resources and infrastructure to make good and efficient use of scarce funding, expertise, data, and biological specimens." This recommendation is especially relevant to SUDEP research due to its low rate of reported incidences. For example, the incidence of SUDEP in community-based studies has varied from 0.09 to 0.35 per 100 person-years [10, 11, 12, 13]. A statistically significant cohort of patients for SUDEP study requires meticulous, prospective follow up of a large population that is at an elevated risk, best represented by the Epilepsy Monitoring Unit (EMU) patient population. Hence, multiple EMUs need to collaborate, share data for building a larger cohort of potential SUDEP patient using state-of-the-art informatics and data analytics infrastructure.

In this paper we present the architecture and initial deployment results of MEDCIS, a Multi-Modality Epilepsy Data Capture and Integration System for data integration across multiple EMUs with both retrospective and prospective patient information. MEDICS offers the following collection of main functionalities, each of which has been tested and validated independently:

1. A standardized data entry platform for patient information at different points of care [14];
2. An epilepsy-focused natural language processing (NLP) tool to extract patient information from clinical free text in existing patient records [15, 16];
3. An integrated signal processing application that will allow clinicians to seamlessly interface between signal data and patient information [17, 18, 19]; and
4. A query environment to identify patient cohorts using data integrated from multiple sources based on a shared ontology [20, 21, 22].

1 Background

MEDCIS has been developed as a part of the NINDS-funded Prevention and Risk Identification of SUDEP Mortality (PRISM) project. PRISM has been led by Case Western Reserve University (CWRU) and involves participating EMUs at the University of California Los Angeles (UCLA) Ronald Reagan Medical Center, Northwestern Memorial Hospital at Northwestern University, and the National Hospital for Neurology and Neurosurgery at University College London (UCL). As part of the PRISM project, we have made significant progress in epilepsy informatics, specifically in area of scalable computing for electrophysiological data using cloud-computing tools [17, 18], paradigm-changing applications of terminological systems for epilepsy research including data capture and data visualization [19, 21], and ontology-driven federated approach to large-scale data integration across multiple centers [20, 22]. This section provides a brief overview of the components that have been developed as a part of an overall integrated environment.

1.1 Epilepsy and Seizure Ontology (EpSO)

EpSO [22] models the necessary domain concepts to describe epilepsy phenotype data at significant level of detail by following an established four-dimensional classification framework in epilepsy [23]. EpSO covers concepts of seizures, location of seizures, etiology and related medical conditions according to the four-dimensional scheme. In addition, it models EEG patterns and comprehensive drug information (anti-epileptic, neuroleptic, and anti-depressants) by using the U.S. National Library of Medicine RxNorm standard [24]. EpSO concepts are mapped to the NINDS Common Data Elements (CDE), which represents nine categories of terms describing imaging, neurological exam, neuropsychology, seizures, and syndromes.

1.2 The Ontology-driven Patient Information Capture (OPIC) system

OPIC uses EpSO to implement a flexible web-based interface to capture data describing demography, patient history, details of paroxysmal events, medication, results of prior electrophysiological evaluations, and patient diagnosis. OPIC leverages EpSO to automatically generate multi-level drop menus that are populated with only relevant terms based on previous user selection (skip patterns) and branching logic to model combinations of user selections. Results of patient evaluation in form of EEG, ECG, and other image files can be directly uploaded and attached with clinical reports in OPIC. The OPIC forms are primarily composed the of structured data entry widgets that reduce user-generated errors, support automated consistency checking, and ensure data completeness, using EpSO as the reference terminology system.

1.3 Epilepsy Data Extraction and Annotation (EpiDEA)

EpiDEA [15, 16] is an ontology-driven clinical free text processing system that extends the clinical Text Analysis and Knowledge Extraction System (cTAKES) [25] for analyzing epilepsy-specific clinical reports. EpiDEA processes two types of textual content in clinical notes: the semi-structured sections with attribute-values pairs and the unstructured sections with sentence-based text. An EpSO-driven epilepsy named entity recognition module and a negation detection module processes the output of these modules. EpSO is used in EpiDEA to support three functionalities: term disambiguation, term normalization, and query expansion using subsumption reasoning. For evaluation, EpiDEA has been used to create a database of 500 patients retrospectively with high precision and recall.

1.4 Cloudwave

Electrophysiological signal data, such as EEG, are often used as gold standard in the diagnosis and treatment of epilepsy. However, signal information generated during a patient's admission in an EMU results in very large size multi-modal datasets that cannot be managed using traditional standalone signal processing applications. This is especially important in case of multi-center collaborative clinical studies that require researchers to share and interact with signal data in real time. To address this challenge, we introduced the Cloudwave platform [19] that features a Web-based intuitive signal analysis interface integrated with a Hadoop-based data processing module implemented on clinical data stored in a "private cloud." Cloudwave provides real-time rendering of multi-modal signals with "montages" for signal feature characterization of multi-modal patient data. Cloudwave also supports signal processing [17] with several magnitudes of speed increase over traditional computing environment.

1.5 VISual Aggregator and Explorer (VISAGE)

VISAGE (Visual Aggregator and Explorer) is a query interface for clinical research cohort search [26]. It was developed for Physio-MIMI (Multi-Modality, Multi-Resource Environment for Physiological and Clinical Research), a multi-CTSA-site collaborative project. Physio-MIMI provides an ontology-driven framework for a federated approach to data integration. The interface design features of VISAGE include auto-generated slider bar, selection boxes, and built-in charting. VISAGE also includes administrative and query lifecycle management functionalities, such as role-based access control, auditing, query builder, query manager, and query explorer. VISAGE is an interface framework, which can not only ingest ontologies in the OWL format, but also unify ontology navigation activities with query widget generation [27, 28].

2 Methods

In this section we describe the MEDCIS architecture that integrates the components described in the Background section together into a robust and comprehensive system. The robustness of MEDCIS rests on the centralized usage of the EpSO as the common reference terminology across all of the components (Fig. 1).

The consistent use of EpSO in all MEDCIS components is an important step in achieving the architecture integrity. In the following sections we describe in more detail the method and steps of importing EpSO to VISAGE, and the semi-automated mappings that results in unique and beneficial interface features.

2.1 Importing EpSO

We use the Apache Jena Ontology API for parsing the EpSO OWL file to extract all the classes while preserving the class hierarchy that will be used in the query execution module to support subsumption reasoning. The extracted classes and their hierarchical structure are saved in a comma separated value (CSV) file format and imported into VISAGE using a Ruby language script. The imported classes can then be easily searched and navigated by clinicians, physicians, nurses, trainees, biostatisticians, epidemiologists, oncologists, and investigators from non-clinical disciplines in VISAGE query builder to compose query for cohort identification.

2.2 Data mapping and query

The federated data integration approach in Physio-MIMI requires the use of explicit mappings between the source database and the domain ontology, such as EpSO, for query translation and query execution. For MEDCIS, all the relational database components are mapped to appropriate EpSO ontology concepts manually through consultation between the informaticians and epileptologists to ensure quality of mappings. For example, in the table storing the patients interictal EEG pattern information, the column for the pattern content is mapped to EpSO concept "InterictalPattern," and the column for the pattern location is mapped to the concepts data type property "hasLocation." The mapping also supports the use of ontology concepts for query construction in the VISAGE query builder module.

We use a federated data integration approach in MEDCIS to allow cross-cohort queries over data from multiple centers. Federated data integration is a flexible alternative approach to traditional centralized data warehouse approach that requires periodic Extract Transform Load (ETL) processes to keep data updated in the data warehouse. The federated approach is ideally suited for multi-center studies, allowing tracking and control of data by individual centers while

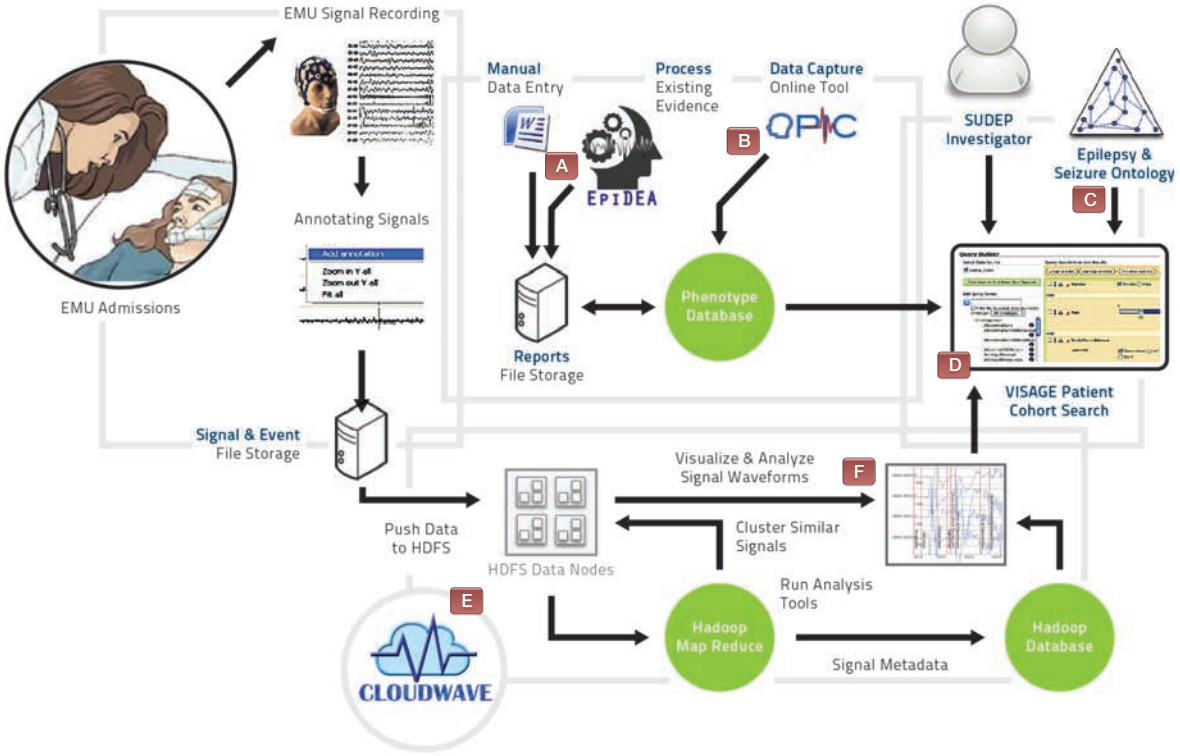

Figure 1: Architecture and data workflow of MEDCIS. A. EpiDEA is used for retrospective information extraction from clinical free-text; B. OPIC is used for prospective structured data capture; C. EpSO is used for mostly other components behind the scenes, but is most directly visible in the VISAGE query interface, which incorporates a built-in ontology browser; D. Once data from EpiDEA and OPIC are ingested into a common database, possibly from multiple sources, the VISAGE interface can be directly accessed by investigators to perform cohort search; E. Multi-modal signal data is processed and annotated using distributed a cloud-computing approach; F. The signal data can be visualized based on the cohort returned from VISAGE, which provides a direct link to the signal data and other clinical documents.

allowing collaborators with appropriate credentials to query the data. Using EpSO as the common terminology schema, MEDCIS allows integrated querying of data from multiple EMUs. The data from each EMU is maintained in separate databases and mapped to EpSO. After mapping, MEDCIS provides seamless access for comprehensive comparative studies of SUDEP and near-SUDEP cases vs. cohort survivors with subjects from participating EMUs.

The key objectives of the VISAGE query interface is to allow clinicians to compose the queries using terms that they are familiar with, combine the terms in different ways (e.g. AND, OR), and explicitly specify negation of specific conditions (e.g. patient not prescribed Keppra). We have already shown in the Physio-MIMI project that VISAGE has multiple advantages over traditional query composition interfaces that often closely reflected the SQL query structure, which is not an intuitive structure for clinical researchers. MEDCIS instantiates the design template of VISAGE using EpSO, thus achieving an interface specifically for the multi-center SUDEP study.

2.2.1 Query widget composition

Each concept in EpSO can generate a visual "query widget" that reflects the specific type of the concept and includes the sub-classes of the concept. For example, a researcher searching for patients with Aura can just select the concept Aura from the "ontology search and browsing" section (Fig. 3), and the appropriate query widget is automatically generated (Fig. 2). The top part of the query widget is the "Aura" class hierarchy as defined in EpSO, and by default includes all its subclasses. In addition to its subclasses, Fig. 2 also shows the ontology property associated with a given class, for example an Aura is associated with the laterality in a patient. The query widget automatically identifies the appropriate values for the laterality information associated with an Aura and displays on the interface for selection by the user.

To explore subclasses of a concept such as "AuditoryAura," a user can click "AuditoryAura" and a new widget is rendered in the query composition interface with specific subclasses of the concept (lower part of Fig. 2). This seamlessly provides the ontological browsing of the concept hierarchy. The user can also easily remove specific query widgets that are no longer needed. This allows users to flexibly modify and update their query structure as they explore the ontology classes and are interested in exploring new hypothesis.

Figure 2: Query widget for the concept "Aura," which automatically generates the display boxes for its subclasses, including "AuditoryAura" (upper). Clicking "AuditoryAura" automatically generates the display boxes for its subclasses as well (lower).

2.2.2 Query generation

The query widgets are translated into the SQL query statement that is executed over the relational database storing the patient data. For each query widget, the EpSO instantiated VISAGE interface records the identifier concept, query concept, data type property of the query concept as well as their selections. It relies on the "database to ontology" mapping to generate the appropriate query. The VISAGE query module does not require each ontology concept to be mapped to a database component. Instead, it leverages the ontology class structure to search for the closest mapped ancestor of the concept that forms the query widget to generate the relational database query. For example, the concept "Aura" is not mapped to any of the data source column, although VISAGE automatically find its closest ancestor "Seizure" which is mapped to the data source column capturing the seizure semiology information.

In the next step, the query generation module identifies the relational database column labeled as "seizure_semiology" found in the table "seizure_semiologies." In addition to the class, the original de-identified discharge summary for the selected patient is also retrieved using the DocumentID column in the "seizure semiologies" table. The property of the class, such as "Laterality" of "AuditoryAura," is mapped to the column laterality in the table "seizure_semiologies." The following sample SQL query statement is created by the query generation module for a query to identify a patient cohort with "Auditory Aura" and having "Right" laterality:

```
SELECT count(DISTINCT seizure_semiologies.`doc`)
FROM seizure_semiologies
   WHERE (CAST(seizure_semiologies.`seizure_semiology` AS CHAR(255))
   IN ('AuditoryAura', 'ComplexAudi-toryAura', 'ElementaryAuditoryAura) and
   CAST(seizure_semiologies.`laterality` AS CHAR(255)) IN ('Right'))
```

An important feature of the query generation module is the ability to support subsumption reasoning based on the EpSO class hierarchy. For example, selecting "Aura" not only includes the eight subtypes as indicated in Fig. 3, but also includes all their descendants. Multiple query widgets can be combined by AND or OR, depending on how the user groups the widgets (Fig. 3).

3 Results

Our prototype implementation involved patients from University Hospitals Case Medical Center (UH CMC) EMU and the EMU at Northwestern Memorial Hospital (NMH) of Northwestern University (under an appropriate IRBs and Data Use Agreement). Multi-modal data of a total of 936 epilepsy patients are currently in MEDCIS. Of the 936 patients, 504 were processed through EpiDEA retrospectively and 432 were captured prospectively using OPIC. All patients processed through EpiDEA were from UH CMC EMU, and 57 captured by OPIC were from NMH. Patients from UH CMC EMU and NMH were stored in different databases and then federated through MEDCIS using EpSO and our mapping module.

For the 504 patients EpiDEA processed a total of 100,836 sentences, 603,605 word tokens and 250,387 noun phrases. 212,246 noun phrases were mapped to appropriate EpSO classes. EpiDEA achieved an overall precision of 93.59%, a recall of 84.01% and an F-measure of 88.53%, as reported in [15]. The MEDCIS database schema consisted of seven tables capturing information about etiology, epileptogenic zone, seizure semiology, lateralizing sign, interictal EEG pattern, ictal EEG pattern, and medication, in addition to demographics.

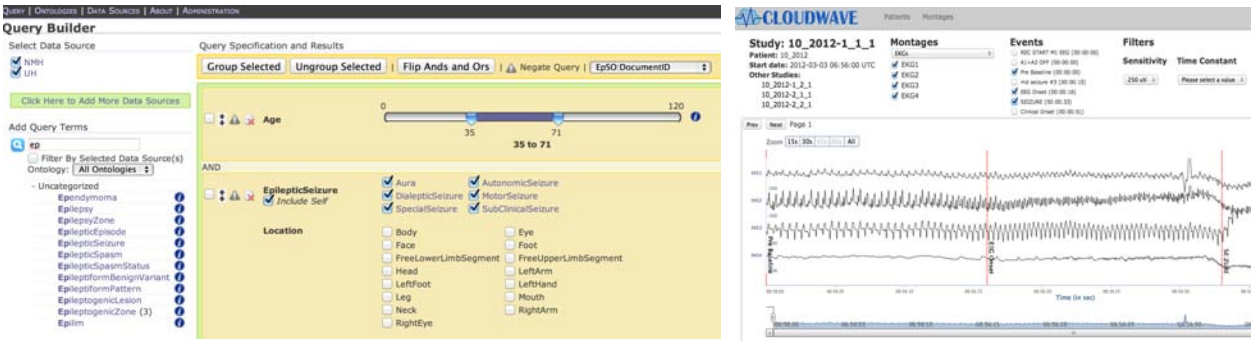

Figure 3: Left: Screenshot of the VISAGE cohort search interface guided by the EpSO ontology. Data from multiple sites are mapped to EpSO, allowing VISAGE to query across projects. The query interface is "driven" by EpSO in that the available seizure types and locations are automatically generated as check boxes for user selection. Right: Screenshot of the Cloudwave web-based signal visualization interface featuring montage composition, events overlay, and a dashboard displaying positioning information which allows the signal to be rendered at multiple desirable resolution.

Multi-modal signal data of a subset of the patients from the UH CMC EMU were linked to Cloudwave through the VISAGE interface. More than 77GB of signal data were processed using the Cloudwave pipeline and made available for rendering through the web-interface.

3.1 Query result rendering

Query results are rendered in format as shown in Fig. 4, listing each patient's gender, age, epileptogenic zone, and EEG pattern as well as location that are clinically relevant.

3.2 Linking to multi-modal data

VISAGE provided a hyperlink (the first column of the table in Fig. 4) to the original discharge summary report and electrophysiological signal data (Fig. 5) of the patient that can be reviewed further by the clinical researcher.

3.3 Evaluation

Each of the MEDCIS components already have their respective evaluations performed and reported as published results [14, 15, 17]. The basic functionality of the VISAGE query environment was evaluated in terms of the usability by clinical investigators as part of the Phsyio-MIMI project [26].

For MEDCIS, our evaluation focused on two integrative aspects. One is expressiveness (Section 3.3.1): the ability

EDF/Discharge Summary	Doc number	Gender	Age	Epileptogenic Zone	EEG Pattern
view	2012_32	Female	26	**LobarEpileptogenicZone**: LeftTemporalLobe, RightTemporalLobe;	**Spike**: RightTemporalLobe, LeftTemporalLobe; **IntermittentSlowActivity**: RightTemporalLobe, LeftTemporalLobe; **SeizurePattern**: LeftTemporalLobe;
	De141	Female	57	**LobarEpileptogenicZone**: RightAnteriorTemporalLobeSegment, TemporalLobe;	**Spike**: RightMesialTemporalLobeSegment, TemporalLobe; **SeizurePattern**: TemporalLobe, RightMesialTemporalLobeSegment;

Figure 4: Sample screenshot of the query result. The result is displayed in a tabular format with data for key fields shown.

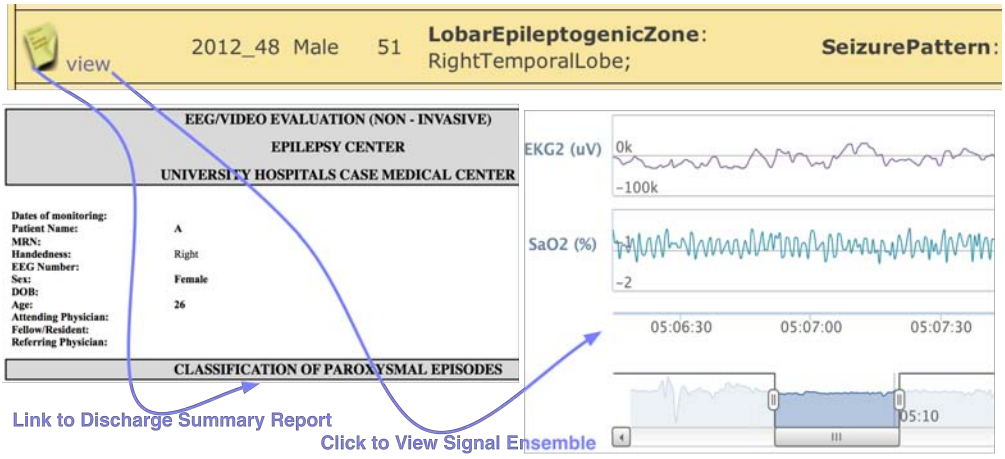

Figure 5: Sample screenshot of the links from query results to discharge summary reports and Cloudwave viewer.

of the query interface to support the type of questions a clinical investigator would like to ask. The other is validity (Section 3.3.2): for those questions that can be translated into appropriate queries, the degree of agreement that the data reported in the VISAGE resulting reports with the information contained in the original patient discharge summaries.

3.3.1 Expressiveness of the EpSO-driven query interface

We focused on the utility of the EpSO domain-specific ontology in supporting the intuitive construction of queries of clinical interest in the PRISM project. 40 questions of clinical interest were formulated by clinical investigators in the UH CMC EMU. Three such questions that were captured using VISAGE are displayed below. Figure 6 (top of next page) shows the screen capture of the query corresponding to the first question.

- Find all patients ages between 20-65 with generalized tonic clonic seizure exhibiting lateralizing sign.
- Find all female patients who have taken Depakote in the past, are currently on Keppra, with either abdominal aura or autonomic aura.
- Find all patients with right visual aura and slow spike EEG pattern from left occipital lobe.

Of the 40 questions, about 26% did not have a direct translation to a query in VISAGE. The non-translatable questions can be classified into three types.

The first type of questions unable to be captured in VISAGE is due to complexity. For example, the question "Find all patients who had been on only two anti-epileptic medications" did not have a simple translation. There are 144 distinct epileptic related drugs. Take a combination of exactly two from this list will result in 10296 choices. This clearly requires a program to execute, and is not an issue that can be easily addressed by a query interface such as VISAGE directly, as far as we know.

The second type of questions unable to be captured in VISAGE is due to limited information capture in the data source. For example, the query "All patients with history of illegal drug use, now or in the past (psychosocial history) and having epileptic paroxysmal episodes (diagnosis)" is not supported because no data on illegal drug use were captured in the EMU.

The third type of questions unable to be captured in VISAGE is due to the incompleteness of the EpSO terminology system. For example, we were not able to capture "All patients with diagnosis of epileptic paroxysmal episodes and periodic limb movement disorder/nocturnal myoclonus" because EpSO has not covered diseases such as "limb movement disorder." This points to the need to continue expanding and evolving EpSO concurrently with the need and scientific advances in the field.

In summary, of the 17 questions not captured by VISAGE, 9 were due to complexity of translation, 5 due to limited source information, and 3 due to terminology incompleteness.

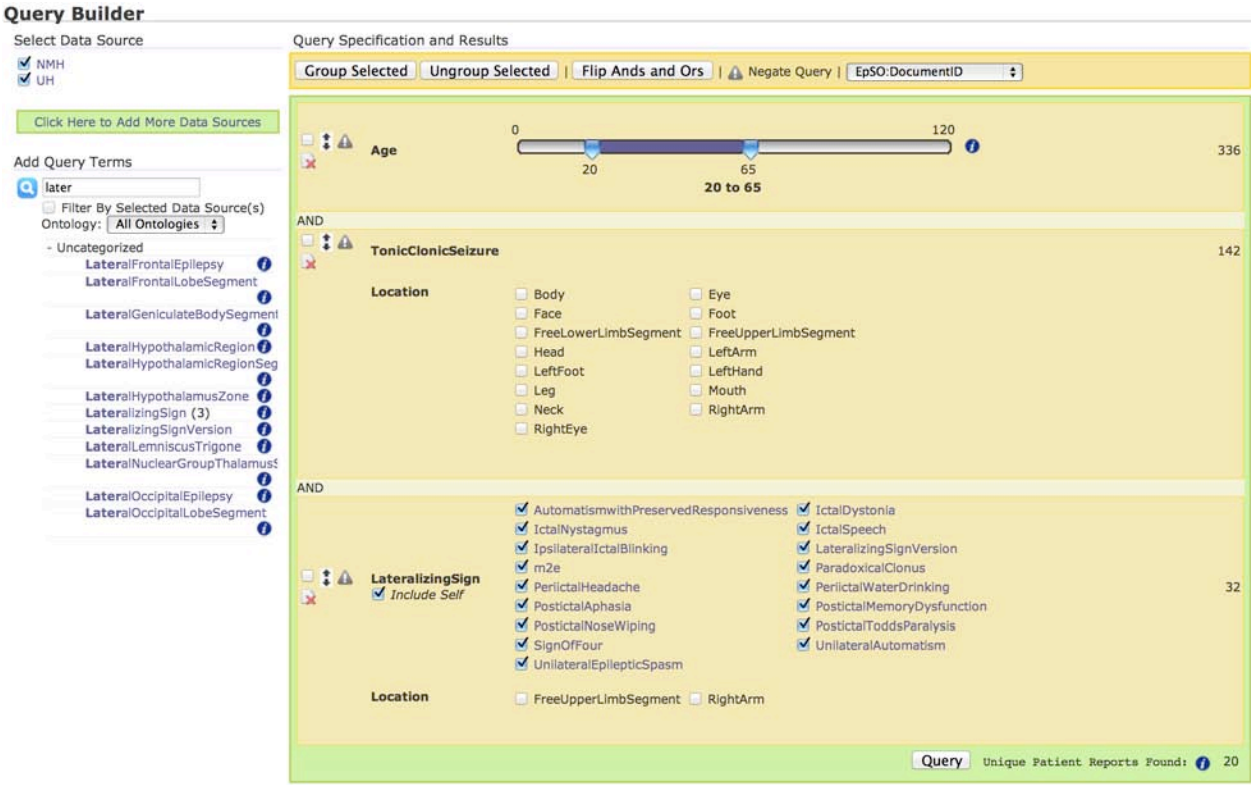

Figure 6: Screenshot of VISAGE query interface corresponding to the criteria "all patients ages between 20-65 with generalized tonic clonic seizure exhibiting lateralizing sign."

3.3.2 Validity of query results against the ground truth

For the 74% of the remaining questions captured using VISAGE queries, we manually validated their correctness by using the linked discharge summery reports as primary source, and inspected the results to be correct. However, since EpiDEA, as any other NLP tool, cannot possibly reach a 100% precision and a 100% recall, its actual precision of 93.59% and recall of 84.01% will impact the query results compared to ground truth (i.e., information found in discharge summaries). We expect OPIC captured patient information to achieve near 100% precision and near 100% recall, barring human data entry errors (although we have not independently evaluated this aspect of data entry quality).

4 Discussions

The functionality of MEDCIS, in terms of query composition, is only limited by the number of concepts modeled in EpSO. At present EpSO has not covered all existing epilepsy subspecialties, such as pediatric epilepsy. As the PRISM project continues, we are engaging the epilepsy community to expand and enhance the concepts modeled in EpSO to address this limitation. We also propose to conduct a comprehensive user survey, spanning six months, with the new batch of medical residents in the UH CMC EMU for further analysis of MEDCIS features. This will help us to maintain and update MEDCIS with new features according to changing user requirements in the PRISM project.

A larger EMU consortium has been formed, involving additional EMUs. Multi-modal physiological, biochemical, phenotypic, genetic and imaging data are to be collected for a targeted number of 2500 epilepsy patients for the next five years. MEDCIS has been adopted as the informatics and data infrastructure hosting this unique and largest nationally shared SUDEP research resource.

The reported SUDEP incidence in adult EMUs is about 5 per 1000 per year [29]. Since SUDEP is a rare event, we had no SUDEP incidence at UH CMC EMU while the patients were under active mornitoring during the PRISM project. Two SUDEP deaths among the UH CMC EMU patients occurred outside the EMU. In the next five years, we expect 10 to 20 SUDEP cases in UH CMC EMU, accounting for patient population growth. Prospectively capturing

all available EMU patient information, and sharing of such information from multiple EMUs, is critical for advancing the understanding the mechanism of SUDEP.

5 Conclusion

This paper presented key architecture and interface features of the MEDCIS platform to address the challenges of integrating structured and semi-structured information from multiple EMUs for SUDEP research. Our experience shows that the ontology-driven architecture for MEDCIS coupling the EpiDEA clinical free text processing tool, the OPIC structured data capturing interface, and the VISAGE query interface, provides a scalable solution to the data extraction and querying requirements in multi-center clinical research projects exemplified by the PRISM study.

Towards Drug Repositioning: A Unified Computational Framework for Integrating Multiple Aspects of Drug Similarity and Disease Similarity

Ping Zhang, PhD, Fei Wang, PhD, Jianying Hu, PhD
Healthcare Analytics Research, IBM T.J. Watson Research Center, New York, USA

Abstract

In response to the high cost and high risk associated with traditional de novo drug discovery, investigation of potential additional uses for existing drugs, also known as drug repositioning, has attracted increasing attention from both the pharmaceutical industry and the research community. In this paper, we propose a unified computational framework, called DDR, to predict novel drug-disease associations. DDR formulates the task of hypothesis generation for drug repositioning as a constrained nonlinear optimization problem. It utilizes multiple drug similarity networks, multiple disease similarity networks, and known drug-disease associations to explore potential new associations among drugs and diseases with no known links. A large-scale study was conducted using 799 drugs against 719 diseases. Experimental results demonstrated the effectiveness of the approach. In addition, DDR ranked drug and disease information sources based on their contributions to the prediction, thus paving the way for prioritizing multiple data sources and building more reliable drug repositioning models. Particularly, some of our novel predictions of drug-disease associations were supported by clinical trials databases, showing that DDR could serve as a useful tool in drug discovery to efficiently identify potential novel uses for existing drugs.

Introduction

The inefficiency of pharmaceutical drug development with high expenditure but low productivity has been widely discussed[1, 2]. Drug repositioning, the process of finding additional indications (i.e., diseases) for existing drugs, presents a promising avenue for identifying better and safer treatments without the full cost or time required for *de novo* drug development. Candidates for repositioning are usually either market drugs or drugs that have been discontinued in clinical trials for reasons other than safety concerns. Because the safety profiles of these drugs are known, clinical trials for alternative indications are cheaper, potentially faster and carry less risk than *de novo* drug development. Any newly identified indications can be quickly evaluated from phase II clinical trials. Drug repositioning can reduce drug discovery and development time from 10-17 years to potentially 3-12 years[3]. Therefore, it is not surprising that in recent years, new indications, new formulations, and new combinations of previously marketed products accounted for more than 30% of the new medicines that reach their first markets[4]. Drug repositioning has drawn widespread attention from the pharmaceutical industry, government agencies, and academic institutes. However, current successes in drug repositioning have primarily been the result of serendipitous events based on *ad hoc* clinical observation, unfocused screening, and "happy accidents". Comprehensive and rational approaches are urgently needed to explore repositioning opportunities.

A reasonable systematic method for drug repositioning is the application of phenotypic screens by testing compounds with biomedical and cellular assays. However, this method also requires additional wet bench work of developing appropriate screening assays for each disease being investigated, and it thus remains challenging in terms of cost and efficiency. Big data analytics for both drugs and diseases provide an unprecedented opportunity to uncover novel statistical associations between drugs and diseases in a scalable manner. Many computational methods have been developed in this direction, including: (1) matching drug indications by their disease-specific response profiles based on the Connectivity Map (CMap) data[5, 6]; (2) predicting novel associations between drugs and diseases by the "Guilt by Association" (GBA) approach[7]; (3) utilizing structural features of compounds/proteins to predict new targets or indications, such as molecular docking[8, 9], and quantitative structure-activity relationship (QSAR) modelling[10]; (4) identifying associations between drugs and diseases in genetic activities, such as genome-wide association study (GWAS)[11], pathway profiles[12], and transcriptional responses[13]; (5) constructing drug network and using network neighbors to infer novel drug uses based on phenotypic profiles, such as side effects[14-16], and gene expression[17, 18]. All of these methods only focus on different aspects of drug/disease activities and therefore result in biases in their predictions. Also, these methods suffer from the noise in the given information source. Recently, several integrative methods which combine chemical, genetic, or phenotypic features were proposed to predict drug indications, for example, PREDICT[19], SLAMS[20], PreDR[21], Li and Lu[22], Huang *et al*[23], and Napolitano *et al*[24].

In this paper, we propose a unified computational framework for drug repositioning hypothesis generation, by integrating multiple **D**rug information sources and multiple **D**isease information sources to facilitate drug **R**epositioning tasks (DDR). DDR utilizes drug similarity network, disease similarity network, and known drug-disease associations to explore the potential associations among other unlinked drugs and diseases. In the experiment, we investigate three types of drug information (i.e., chemical structure, target protein, and side effect) and three types of disease information (i.e., phenotype, ontology, and disease gene). The proposed framework is also extensible, and thus DDR can incorporate additional types of drug/disease information sources.

Compared to prior integrative drug repositioning methods, it is worthwhile to highlight the following novel aspects that DDR can achieve simultaneously: (1) DDR can predict additional drug-disease associations by considering both drug information and disease information. With the exception of PREDICT[19], which integrates drug similarity scores and disease similarity scores using unweighted geometric mean, other integrative methods only consider either some drug information sources or some disease information sources. (2) DDR can determine interpretable importance of different information sources during the prediction. To our knowledge ours is the first study to do so. (3) As by-products, DDR can also discover the drug and disease groups, such that the drugs or diseases within the same group are highly correlated with each other, thus providing additional insights for targeted downstream investigations including clinical trials.

Construction of Drug Similarity and Disease Similarity Measures

In this section we introduce drug/disease similarities to quantify the degree of sharing common characteristics between pairs of drugs/diseases. A drug/disease similarity provided for a pair of drugs/diseases is a score that ranges from 0 to 1, with 0 representing the lowest similarity and 1 standing for the highest similarity. For each drug pair, we calculated three types of similarities based on chemical structures, target proteins, and side effects. For each disease pair, we calculated three types of similarities based on disease phenotypes, disease ontology, and disease genes.

Drug Similarity of Chemical Structures $\mathbf{D^{chem}}$. It is generally believed that drugs with similar chemical structures would carry out common therapeutic function, thus likely treat common diseases. We calculated the first drug pairwise similarity based on a chemical structure fingerprint corresponding to the 881 chemical substructures[25] defined in PubChem database[26]. Each drug *d* was represented by an 881-dimensional binary profile *h(d)* whose elements encode for the presence or absence of each PubChem substructure by 1 or 0, respectively. Then the pairwise chemical similarity between two drugs *d* and *d'* is computed as the Tanimoto coefficient of their chemical fingerprints:

$$D^{chem}_{d,d'} = \frac{h(d) \bullet h(d')}{|h(d)| + |h(d')| - h(d) \bullet h(d')} \quad (1)$$

where $|h(d)|$ and $|h(d')|$ are the counts of substructure fragments in drugs *d* and *d'* respectively. The dot product $h(d) \bullet h(d')$ represents the number of substructure fragments shared by two drugs.

Drug Similarity of Target Proteins $\mathbf{D^{target}}$. A drug target is the protein in the human body whose activity is modified by a drug resulting in a desirable therapeutic effect. Drugs sharing common targets often possess similar therapeutic function. We collected all target proteins for each drug from DrugBank[27]. Then we calculated the pairwise drug target similarity between drugs *d* and *d'* based on the average of sequence similarities of their target protein sets:

$$D^{target}_{d,d'} = \frac{1}{|P(d)||P(d')|} \sum_{i=1}^{|P(d)|} \sum_{j=1}^{|P(d')|} SW(P_i(d), P_j(d')) \quad (2)$$

where given a drug *d*, we presented its target protein set as *P(d)*; then $|P(d)|$ is the size of the target protein set of drug *d*. The sequence similarity function of two proteins *SW* was calculated as a Smith-Waterman sequence alignment score[28].

Drug Similarity of Side Effects $\mathbf{D^{se}}$. Drug side effects, or adverse drug reactions, indicate the malfunction by off-targets. Thus side effects are useful to infer whether two drugs share similar target proteins and treat similar diseases. We obtained side effect keywords from SIDER[29], an online database containing drug side effect information extracted from package inserts using text mining methods. Each drug *d* was represented by 4192-dimensional binary side effect profile *e(d)* whose elements encode for the presence or absence of each of the side

effect key words by 1 or 0 respectively. Then the pairwise side effect similarity between two drugs *d* and *d'* is computed as the Tanimoto coefficient of their side effect profiles:

$$D^{se}_{d,d'} = \frac{e(d) \bullet e(d')}{|e(d)| + |e(d')| - e(d) \bullet e(d')} \tag{3}$$

where $|e(d)|$ and $|e(d')|$ are the counts of side effect keywords for drugs *d* and *d'* respectively. The dot product $e(d) \bullet e(d')$ represents the number of side effects shared by two drugs.

Disease Similarity of Phenotypes S^{pheno}. Disease phenotypes indicate phenotypic abnormalities encountered in human diseases. We used the phenotypic similarity constructed by van Driel *et al*[30]. The disease phenotypic similarity was constructed by identifying similarity between the MeSH terms[31] appearing in the medical description ("full text" and "clinical synopsis" fields) of diseases from OMIM database[32]. To be specific, each disease *s* in OMIM was represented by *K*-dimensional (*K* is the number of the MeSH terms) MeSH term feature vector *m(s)*: each entry in the feature vector represents an MeSH term, and the counts of the term found for disease *s* are the corresponding feature value. Then the pairwise disease phenotype similarity between two diseases *s* and *s'* is computed as the cosine of the angle between their feature vectors:

$$S^{pheno}_{ss'} = \frac{\sum_{i=1}^{K} m(s)_i m(s')_i}{\sqrt{\sum_{i=1}^{K} m^2(s)_i} \sqrt{\sum_{i=1}^{K} m^2(s')_i}} \tag{4}$$

where $m(s)_i$ denotes the *i*-th entry of the feature vector *m(s)*.

Disease Similarity of Disease Ontology S^{do}. The Disease Ontology (DO)[33] is an open source ontological description of human disease, organized from a clinical perspective of disease etiology and location. The terms in DO are disease names or disease-related concepts and are organized in a directed acyclic graph (DAG). Two linked diseases in DO are in an "is-a" relationship, which means one disease is a subtype of the other linked disease. And the lower a disease is in the DO hierarchy, the more specific the disease term is. We calculated the semantic similarity between any pair of the diseases using the tool DOSim[34]. For a disease term *s* in DO, the probability that the term is used in disease annotations is estimated as p_s, which is the number of disease term *s* or its descendants in DO divided by the total number of disease terms in DO. Then the semantic similarity of two diseases *s* and *s'* is defined as the information content of their lowest common ancestor by:

$$S^{do}_{ss'} = -\log \min_{x \in C(s,s')} p_x \tag{5}$$

where *C(s,s')* is the set of all common ancestors of diseases *s* and *s'*.

Disease Similarity of Disease Genes S^{gene}. Disease-causing aberrations in the normal function of a gene define that gene as a disease gene. We collected all disease genes for each disease from "phenotype-gene relationships" field from OMIM database. Then we calculated the pairwise disease similarity between diseases *s* and *s'* based on the average of sequence similarities of their disease gene sets:

$$S^{gene}_{ss'} = \frac{1}{|G(s)||G(s')|} \sum_{i=1}^{|G(s)|} \sum_{j=1}^{|G(s')|} SW(G_i(s), G_j(s')) \tag{6}$$

where given a disease *s*, we presented its disease gene set as *G(s)*; then $|G(s)|$ is the size of the disease gene set of disease *s*. The sequence similarity function of two disease genes *SW* was calculated as a Smith-Waterman sequence alignment score.

Methodology

In this section we present the details of the proposed DDR approach. Suppose we have *n* information sources to measure drug similarity and *m* information sources to measure disease similarity. Let $\boldsymbol{D}_k \in \mathbb{R}^{n \times n}$ be the drug similarity matrix measured on the *k*-th information source, and suppose there are in total K_d information sources to measure the drug similarities. Similarly, let $\boldsymbol{S}_l \in \mathbb{R}^{m \times m}$ be the disease similarity matrix measured on the *l*-th information source and suppose there are K_s sources to measure the disease similarities. Let $\boldsymbol{U} \in \mathbb{R}^{n \times C_D}$ be the latent drug grouping matrix with C_D the number of drug groups, and $\boldsymbol{U}_{ij}$ indicates the possibility that the *i*-th drug belonging to the *j*-th drug cluster. $\boldsymbol{V} \in \mathbb{R}^{m \times C_S}$ be the latent disease grouping matrix with C_S the number of disease groups, and $\boldsymbol{V}_{ij}$

indicating the possibility that the *i*-th disease belonging to the *j*-th disease cluster. $\boldsymbol{R} \in \mathbb{R}^{n \times m}$ be the observed (i.e., known) drug-disease association matrix with $\boldsymbol{R}_{ij}=1$ if the association between the *i*-th drug and *j*-th disease is observed, and $\boldsymbol{R}_{ij}=0$ otherwise. Then we aim to analyze the drug-disease network by minimizing the following objective:

$$J = J_0 + \lambda_1 J_1 + \lambda_2 J_2 \tag{7}$$

where the three parts in the objective are:

- The reconstruction loss of observed drug-disease associations:

$$J_0 = \| \Theta - U \Lambda V^T \|_F^2 \tag{8}$$

  Here $\boldsymbol{\Theta} \in \mathbb{R}^{n \times m}$ is the estimated dense version of $\boldsymbol{R}$, and $\boldsymbol{\Lambda} \in \mathbb{R}^{C_D \times C_S}$ encodes the relationship between drug clusters and disease clusters.

- The reconstruction loss of drug similarities:

$$J_1 = \sum_{k=1}^{K_d} \omega_k \| D_k - UU^T \|_F^2 + \delta_1 \| \omega \|_2^2 \tag{9}$$

  Here the estimated drug similarity matrix is $\boldsymbol{UU}^T$, and $\omega \in \mathbb{R}^{K_d \times 1}$ is the nonnegative weight vector when aggregating the reconstruction loss on different drug information sources. The L_2 norm regularization is added to avoid trivial solution[35] and $\delta_1 \geq 0$ is the tradeoff parameter.

- The reconstruction loss of disease similarities:

$$J_2 = \sum_{l=1}^{K_s} \pi_l \| S_l - VV^T \|_F^2 + \delta_2 \| \pi \|_2^2 \tag{10}$$

  Here the estimated disease similarity matrix is $\boldsymbol{VV}^T$, and $\pi \in \mathbb{R}^{K_s \times 1}$ is the nonnegative weight vector when aggregating the reconstruction loss on different disease information sources. The L_2 norm regularization is added for the same reasons in equation (9).

Putting everything together, we obtained the optimization problem to be resolved:

$$\min_{\mathbf{U},\mathbf{V},\boldsymbol{\Lambda},\boldsymbol{\Theta},\omega,\pi} J \tag{11}$$

$$\text{subject to } \boldsymbol{U} \geq 0,\ \boldsymbol{V} \geq 0,\ \boldsymbol{\Lambda} \geq 0,\ \omega \geq 0,\ \omega^T \mathbf{1}=1,\ \pi^T \mathbf{1}=1,\ P_\Omega(\boldsymbol{\Theta}) = P_\Omega(\boldsymbol{R})$$

where Ω is the set of indices of the observed associations, and P_Ω is the projection operator on obtaining the entries of a matrix indexed by the indices in Ω. Thus the constraint $P_\Omega(\boldsymbol{\Theta}) = P_\Omega(\boldsymbol{R})$ restricts the estimated drug-disease associations should include the ones that are already observed. Note that to enhance the interpretability of the learned model, we require $\boldsymbol{U}$, $\boldsymbol{V}$, and $\boldsymbol{\Lambda}$ to be nonnegative, ω and π to be in simplexes. As there are lots of symbols and notations involved in problem (11), we summarize them in Table 1. To further help understanding those symbols as well as their roles in problem (11), we also provide a graphical illustration of the main idea of DDR in Figure 1.

Table 1. Notations and symbols of the methodology

Notation	Size	Meaning
$\boldsymbol{D}_k$	n×n	The *k*-th drug similarity matrix
$\boldsymbol{S}_l$	m×m	The *l*-th disease similarity matrix
$\boldsymbol{U}$	$n \times C_D$	Drug cluster assignment matrix
$\boldsymbol{V}$	$m \times C_S$	Disease cluster assignment matrix
$\boldsymbol{\Lambda}$	$C_D \times C_S$	Drug-disease cluster relationship matrix
$\boldsymbol{R}$	n×m	Observed drug-disease association matrix
$\boldsymbol{\Theta}$	n×m	Densified estimation of $\boldsymbol{R}$
ω	$K_d \times 1$	Drug similarity weight vector
π	$K_s \times 1$	Disease similarity weight vector

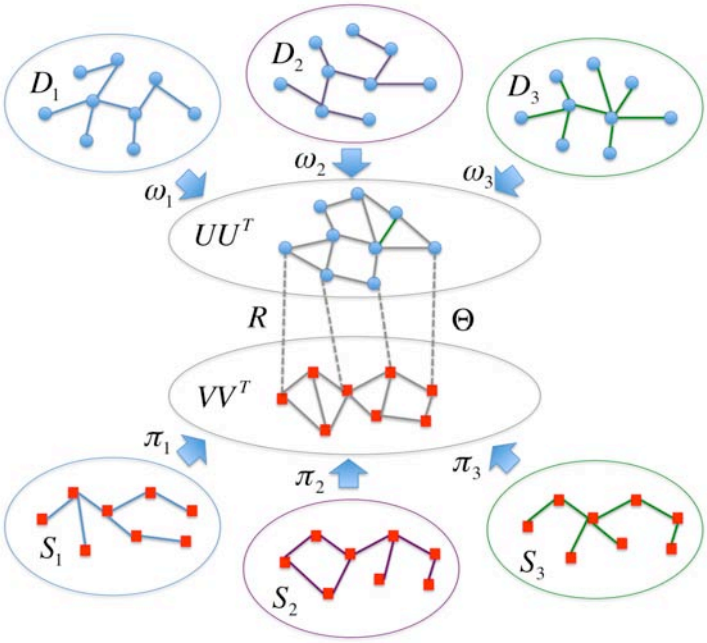

Figure 1. A graphical illustration of the main idea of DDR. There are multiple information sources that we can utilize to construct drug/disease similarities, and the constructed drug/disease similarity matrices are denoted by $\{\boldsymbol{D}_k\}_{k=1}^{K_d}$ or $\{\boldsymbol{S}_l\}_{l=1}^{K_s}$. There is also an observed drug-disease association matrix $\boldsymbol{R}$. Then DDR can learn the drug/disease grouping matrix $\boldsymbol{U}$ or $\boldsymbol{V}$, the estimated drug-disease association matrix $\boldsymbol{\Theta}$ and the importance of different drug/disease information sources ω or π.

Our proposed DDR method integrates multiple drug similarities, multiple disease similarities, and known drug-disease associations to achieve a global estimation on the entire drug-disease network including the intrinsic drug similarity, intrinsic disease similarity, as well as drug-disease associations. DDR formulates such a network estimation problem as a constrained nonlinear optimization problem. Since there are multiple groups of variables involved in the optimization problem (11), we adopt an efficient solution based on the Block Coordinate Descent (BCD) strategy[36]. The BCD approach works by solving the different groups of variables alternatively until convergence. At each iteration, it solves the optimization problem with respect to one group of variables with all other groups of variables fixed. Due to lack of space, details of the BCD solution procedure and its complexity analysis is provided at http://astro.temple.edu/~tua87106/ddr_bcd.pdf.

Results and Discussion

In this section we present experimental evaluation results of the proposed DDR algorithm on a drug repositioning task.

Data Description. The benchmark dataset, which is used to test the performance of DDR using a community standard, was extracted from NDF-RT[37] by Li and Lu[22]. It spans 3,250 treatment associations between 799 drugs and 719 diseases. We considered drug information from three data sources: chemical structure, target protein, and side effect. Thus, three 799×799 matrices were used to represent drug similarities between 799 drugs from different perspectives. Similarly, we considered disease information from three data sources: disease phenotype, disease ontology, and disease gene. Thus, three 719×719 matrices were used to represent disease similarities between 719 human diseases from different perspectives. The presence or absence of known associations between drug and disease was denoted by 1 or 0 respectively. Thus, a 799×719 matrix $\boldsymbol{R}$ used to represent the known drug-disease associations. We plotted the statistic of the known drug-disease associations in Figure 2. In that dataset, most of drugs (75%) treat <5 diseases; 18% of drugs treat 5 to 10 diseases; only 7% of drugs treat >10 diseases (Figure 2(a)). Although the disease hypertension has 78 related drugs, 80% of diseases have only <5 drugs; 10% of diseases have 5-10 drugs; and remaining 10% of diseases have >10 drugs.

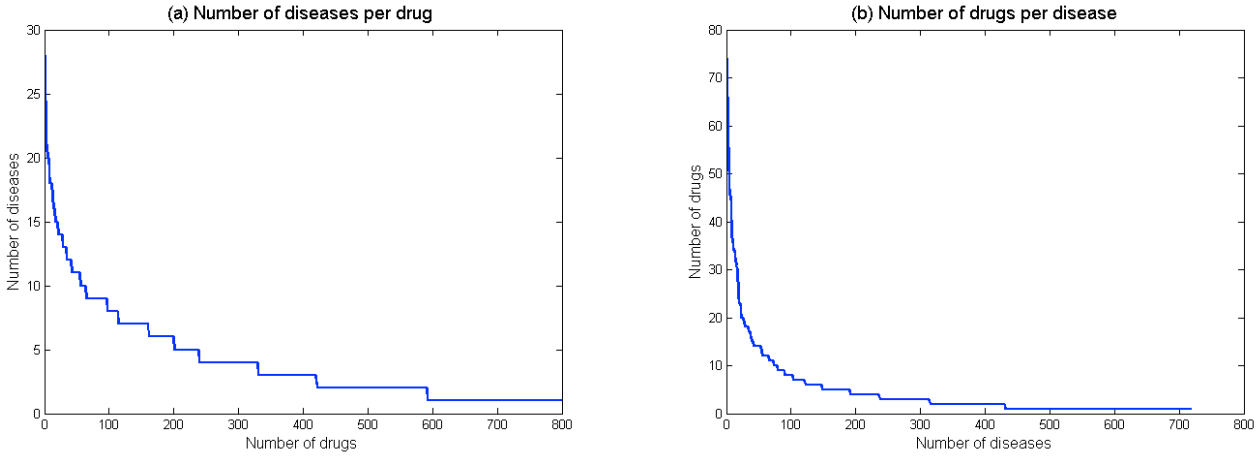

Figure 2. Statistics of the known drug-disease association dataset. (a) The number of indicated diseases per drug. (b) The number of drugs per disease.

Method Comparison. We used a 10-fold cross-validation scheme to evaluate drug repositioning approaches. To ensure the validity of the test cases, we held out all the associations involved with 10% of the drugs in each fold, rather than holding out associations directly. To obtain robust results, we performed 50 independent cross-validation runs, in each of which a different random partition of dataset to 10 parts was used. In our comparisons, we considered five drug repositioning methods: (1) **DDR using Simple Average**. The method only considers reconstruction loss of observed drug-disease associations (i.e., J_0 of objective formula (7) in the methodology section), and assumes each drug/disease source is equally informative. Thus the method uses the average of drug/disease similarity matrices as the integrated drug/disease similarity. (2) **DDR with Weighted Drug Similarity.** The method considers reconstruction losses of observed drug-disease associations and drug similarities (i.e., J_0 and J_1 in objective formula (7)). The method uses the average of disease similarity matrices as integrated disease similarity, and automatically learns drug similarity weight vector (ω) based on the contributions of drug information sources to the prediction. (3) **DDR with Weighted Disease Similarity.** The method considers reconstruction losses of observed drug-disease associations and disease similarities (i.e., J_0 and J_2 in objective formula (7)). The method uses the average of drug similarity matrices as integrated drug similarity, and automatically learns disease similarity weight vector (π) based on the contributions of disease information sources to the prediction. (4) **DDR with Weighted Drug and Disease Similarities.** The method considers all reconstruction losses proposed in the paper (i.e., formula (7) as a whole). The method automatically learns drug similarity weight vector (ω) and disease similarity weight vector (π) together based on the contributions of drug and disease information sources to the prediction. (5) **PREDICT with All Drug and Disease Similarities.** To our knowledge, PREDICT[19] is the only other method could consider both drug and disease information sources. PREDICT uses unweighted geometric mean of pairs of drug-drug and disease-disease similarity measures to construct classification features and subsequently learns a logistic regression classifier that distinguishes between true and false drug-disease associations. PREDICT could not provide weight for each drug/disease information source. Figure 3 shows the averaged ROC curves of 50 runs of the cross-validation for different methods based on the experiment.

Figure 3 shows that our proposed DDR framework is effective for drug repositioning tasks. Without considering reconstruction loss of any similarity measure, DDR using Simple Average obtains an averaged AUC score of 0.7985. When considering weighted drug similarity (i.e., reconstruction loss of drug similarities) or weighted disease similarity (i.e., reconstruction loss of disease similarities), DDRs obtain averaged AUC scores of 0.8508 or 0.8366 respectively. In the experiment, drug-based optimization (i.e., DDR with Weighted Drug Similarity) obtains a higher AUC score than disease-based optimization (i.e., DDR with Weighted Disease Similarity). This could be partially explained with the following reason. The 799 drugs we studied are marketed medications, which usually have rich and precise pharmacological data; thus drug-based optimization might be preferred in this case. For novel drugs or clinical candidates, disease-based optimization might be preferred to overcome missing knowledge in the pharmacology of a drug[38] (e.g., additional targets, unknown side effect). When considering weighted drug similarity and weighted disease similarity together, DDR obtain the highest averaged AUC score (0.8700). The observation

indicates that drug-based optimization and disease-based optimization could be complementary, and computational drug repositioning tasks should optimize both drug similarity and disease similarity. Another observation is PREDICT with All Drug and Disease Similarities obtains an averaged AUC score of 0.8301. Although PREDICT considers drug/disease similarity and utilizes a logistic regression to weigh classification features, the result indicates that their strategy of feature construction (assembles all possible combinations of drug/disease similarity measures together as classification features) is less accurate than DDR.

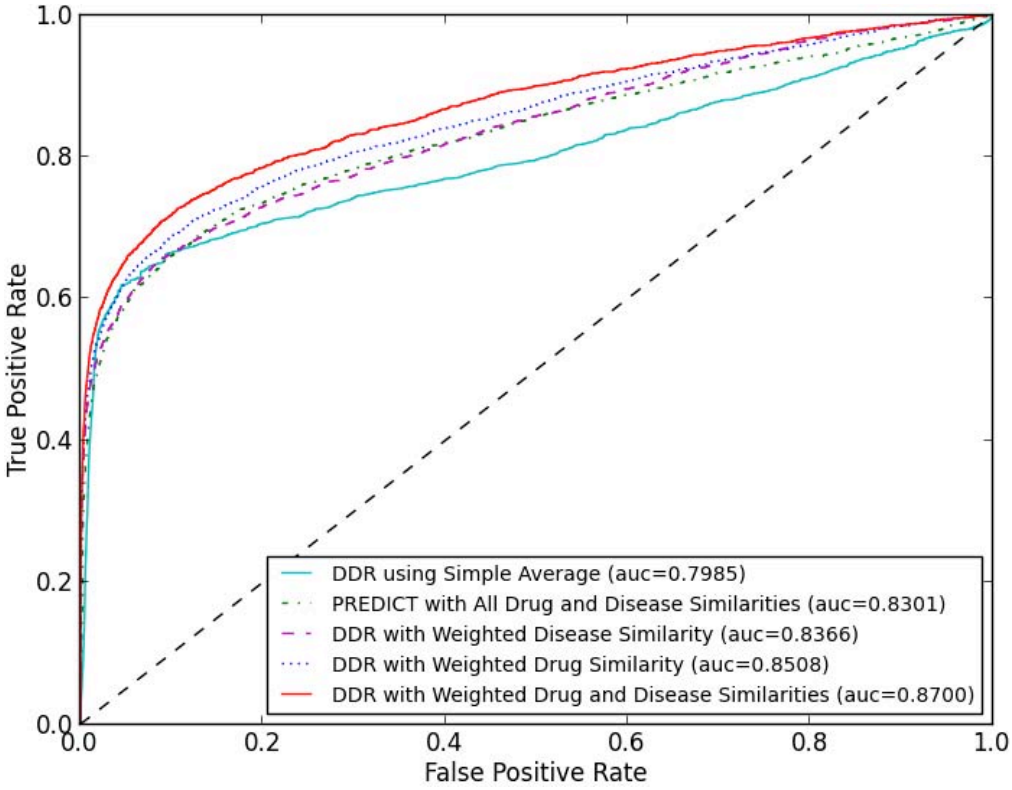

Figure 3. The averaged ROC comparison of five drug repositioning approaches generated from 50 runs of 10-fold cross-validation. Methods are sorted in legend of the figure according to their AUC score.

One "bonus" characteristic of DDR is it provides interpretable importance of different information sources based on their contributions to the prediction. The *i*-th element of drug/disease weight vector ω/π corresponds to the *i*-th drug/disease data sources. Since we constrained ω/π to be in a simplex in problem formula (11), the sum of all elements of ω/π is 1. Obtained from DDR with Weighted Drug and Disease Similarities, the averaged DDR weights of each data source and their standard deviations during the cross-validation experiments are plotted in Figure 4. For drug data sources, chemical structure obtains averaged weight of 0.2744, target protein obtains averaged weight of 0.2295, and side effect obtains a much higher averaged weight of 0.4961 (Figure 4(a)). This could be partially explained with the following reasons. Chemical structure and target protein sources focus on drug's molecular mechanism of action (MOA) from a genotypic perspective. However, the pre-clinical outcomes based on MOA often do not correlate well with therapeutic efficacy in drug development. It is estimated that of all compounds effective in cell assays, only 30% of them could work in animals. Even worse, only 5% of them could work in humans[39]. Side effects are generated when drugs bind to off-targets, which perturb unexpected metabolic or signaling pathways. For marketed drugs, which have relatively complete side effect profiles, side effect information from clinical patients may be seen as valuable read-outs of drug effects directly on human bodies[40] (i.e., with less translational problems). Thus, side effects could server as a promising perspective for drug repositioning. For disease data sources, phenotype obtains averaged weight of 0.4248, disease ontology obtains averaged weight of 0.3958, and disease gene obtains a lower averaged weight of 0.1794 (Figure 4(b)). The lower weight of disease gene data source may be due to the fact that the gap between phenotype (human disease) and genotype (human gene) is too large[41], and the known associations between diseases and genes (obtained from OMIM) are incomplete.

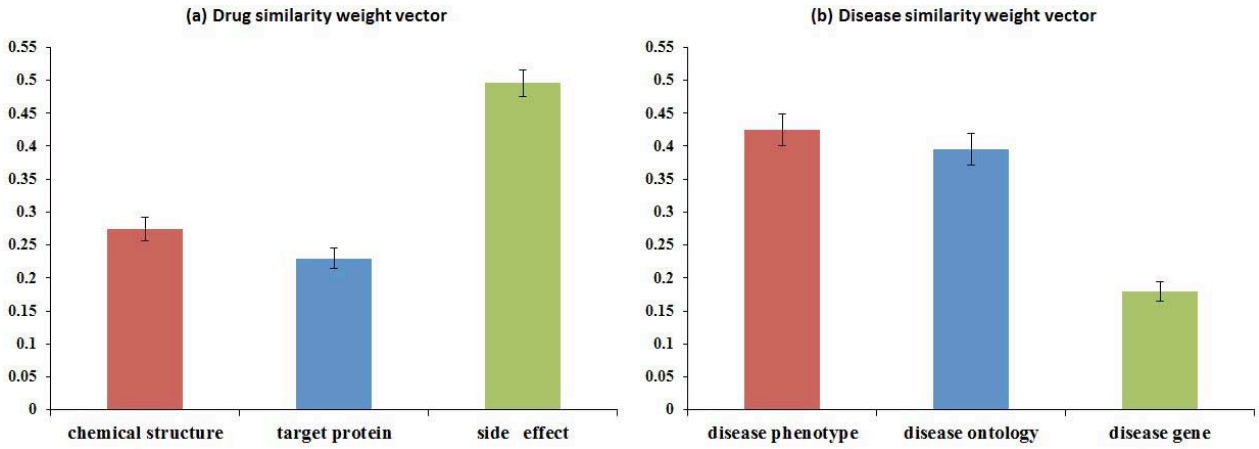

Figure 4. Distribution of averaged weights and standard deviations of the similarity weight vectors obtained by DDR. (a) Drug similarity weight vector ω contains weights of chemical structure, target protein, and side effect data sources. (b) Disease similarity weight vector π contains weights of disease phenotype, disease ontology, and disease gene sources.

Novel Predictions and Case Studies. We performed an additional leave-disease-out experiment to demonstrate the capability of DDR on uncovering drug-disease associations and predicting novel drug candidates for each disease. To ensure the validity of the test cases, we held out all the known drug-disease associations with the tested disease. The validation setting mimics a real-world setting: once rare/unknown diseases without any treatment information arise, a computational drug repositioning method should provide potential drugs based on characteristics (e.g. phenotypes, related genes) of the new diseases and the existing drug/disease similarities. In the experiment, we alternatively leave each disease *i* out and ran DDR (considered weighted drug and disease similarities). More specifically, we set all elements in *i*-th column of matrix $\boldsymbol{R}$ to 0, and used this $\boldsymbol{R}$ along with drug/disease similarity matrices as inputs of DDR. Then we used *i*-th column of the densified estimated matrix $\boldsymbol{\Theta}$ as the drug prediction scores for the disease *i*. In this way, we got prediction scores for all possible associations between the 799 drugs and 719 diseases.

As an example, treatment predictions for Alzheimer's disease (AD) were analyzed. For the six drugs which are known to treat AD, DDR assigned scores of 0.7091 to Selegiline, 0.6745 to Valproic Acid, 0.6348 to Galantamine, 0.5675 to Donepezil, 0.5571 to Tacrine, and 0.5233 to Rivastigmine, which are significantly larger than those of the other 793 drugs (mean and standard deviation are 0.1565±0.1628). Table 2(a) shows the top 10 drugs predicted for AD by our DDR approach. Of the 10 drugs, only three (Selegiline, Valproic Acid, and Galantamine) appear in our known drug-disease association list. The remaining 7 predicted drugs (along with other high-ranked ones in the leave-disease-out experiment) could be considered as drug repositioning candidates for AD. Some predictions are explainable and supported by clinical evidence from ClinicalTrials.gov (i.e., pharmaceutical investigators have been aware of the associations, which are still in the experimental stages). Metformin, a drug commonly used to treat type II diabetes, can help trigger the pathway used to instruct stem cells in the brain to become neural cells[42]. Clinical trial NCT01965756 is under way to evaluate Metformin as a potential therapy for AD. Bexarotene, a skin cancer drug (for cutaneous T-cell lymphoma) that rapidly removed the damaging protein implicated in the progression of the illness from the brains of mice[43], has been tested to treat AD in recent clinical trials (NCT01782742 and NCT02061878). Nilvadipine, a calcium channel blocker (CCB) for treatment of hypertension, also blocks the production of amyloid proteins linked to AD[44]. Nilvadipine has been tested in a clinical trial as a possible treatment for AD in Ireland (NCT02017340).

Another example we analyzed is treatment predictions for Systemic Lupus Erythematosus (SLE). For the three drugs which are known to treat SLE, DDR assigned scores of 0.7269 to Azathioprine, 0.6862 to Triamcinolone, and 0.6374 to Hydroxychloroquine, which are significantly larger than those of the other 796 drugs (mean and standard deviation are 0.1707±0.1617). Table 2(b) shows the top 10 drugs predicted for SLE by our DDR approach. The top 10 predictions include all the three known treatments to SLE, which shows the effectiveness of our method. The remaining 7 predicted drugs (along with other high-ranked ones in the leave-disease-out experiment) could be considered as drug repositioning candidates for SLE. Some predictions are explainable and supported by clinical

evidence from ClinicalTrials.gov. Leflunomide, a pyrimidine synthesis inhibitor, is used to treat moderate to severe rheumatoid arthritis and psoriatic arthritis. A genetic link study shows rheumatoid arthritis and SLE sufferers share a variant of the same STAT4 gene, and therapies developed to treat one disease may possibly be able to treat the other[45]. Therefore, it is not surprising to see Leflunomide is tested as a treatment for SLE in a clinical trial (NCT00637819). Nelfinavir, one of the protease inhibitors, has been approved for use in the treatment of human immunodeficiency virus (HIV). Protease inhibitors have been shown to interfere with binding of anti-double stranded DNA antibodies to their targets (some bindings may lead to organ damage) and may decrease inflammation in SLE[46]. Recently, a clinical trial (NCT02066311) has been proposed to evaluate Nelfinavir as a potential therapy for SLE.

Table 2. Top 10 drugs for diseases Alzheimer's Disease (AD) and Systemic Lupus Erythematosus (SLE) based on DDR predictions

(a) Top 10 drugs predicted for AD

Drug	Prediction Score	Clinical Evidence?
Selegiline*	0.7091	—
Carbidopa	0.6924	No
Amantadine	0.6897	No
Procyclidine	0.6826	No
Valproic Acid*	0.6745	—
Metformin	0.6543	Yes
Bexarotene	0.6426	Yes
Neostigmine	0.6385	No
Galantamine*	0.6348	—
Nilvadipine	0.6159	Yes

(b) Top 10 drugs predicted for SLE

Drug	Prediction Score	Clinical Evidence?
Desoximetasone	0.7409	No
Azathioprine*	0.7269	—
Leflunomide	0.7078	Yes
Fluorometholone	0.7054	No
Triamcinolone*	0.6862	—
Beclomethasone	0.6522	No
Etodolac	0.6445	No
Hydroxychloroquine*	0.6374	—
Nelfinavir	0.6371	Yes
Mercaptopurine	0.6150	No

* denotes the drug is known and approved to treat the disease

Conclusion

We have proposed a general computational framework, called DDR, to explore drug-disease association for drug repurposing hypothesis generation. Our method takes into consideration multiple drug similarities, multiple disease similarities, and known drug-disease associations, to uncover the potential additional associations among other unlinked drugs and diseases. Experimental results demonstrate the effectiveness of the proposed method, and suggest that our method could help identify drug repositioning opportunities, which will benefit patients by offering more effective and safer treatments.

Abstract

Redundant information in clinical notes within electronic health record (EHR) systems is ubiquitous and may negatively impact the use of these notes by clinicians, and, potentially, the efficiency of patient care delivery. Automated methods to identify redundant versus relevant new information may provide a valuable tool for clinicians to better synthesize patient information and navigate to clinically important details. In this study, we investigated the use of language models for identification of new information in inpatient notes, and evaluated our methods using expert-derived reference standards. The best method achieved precision of 0.743, recall of 0.832 and F1-measure of 0.784. The average proportion of redundant information was similar between inpatient and outpatient progress notes (76.6% (SD=17.3%) and 76.7% (SD=14.0%), respectively). Advanced practice providers tended to have higher rates of redundancy in their notes compared to physicians. Future investigation includes the addition of semantic components and visualization of new information.

Introduction

Clinical note documentation in Electronic Health Record (EHR) systems provides clinicians with the ability to store and share detailed contextual health information about patients for the primary purposes of communication, documentation, and billing. Most EHR systems allow functionality of "copy-and-pasting" of texts from a previous note to the current clinical note, which shortens the time clinicians spend on documenting encounters. However, an unintended consequence of copy-and-paste practices is creation of large amounts of replicated patient information within the EHR, especially in patients with complicated care or long hospital stays, thus making notes longer and less readable [1-3].

Notes with significant amounts of redundant information, combined with a large numbers of notes, increases the cognitive burden of clinicians [3-8]. In a time-constrained clinical practice environment, clinicians are limited in their review and synthesis of patient notes. Redundant information in clinical notes creates noise that masks new and clinically relevant information within notes. Moreover, redundant information in clinical notes can also contain a mixture of outdated information or errors in the copied information, making it difficult for clinicians to interpret the data in these notes effectively [4].

Several studies have reported the effect of copy-and-paste documentation behavior in clinical practice [9-11]. Redundant information can also create an integrity problem in clinical notes and create an impression that a note containing significant amounts of copied information is from an author who may not have read or independently constructed the note [9]. For example, in one report, a nurse observed that a historical event that occurred four years prior was subsequently repeated in many clinical notes afterwards [9]. This problem may also result in decreased use of and reliance on the information within clinical notes [6]. Other studies have demonstrated that the combination of redundant information and increased note length results in information overload and difficulties in finding information within notes, thus making narrative communication via notes less effective and efficient for patient care [10, 11].

Previous studies have found large amounts of redundant information in both inpatient and outpatient notes with automated methods [12, 13]. Wrenn et al. used global alignment techniques to quantify redundancy in inpatient clinical notes [12]. They found an average of 78% and 54% information duplicated from previous documents in signout and progress notes, respectively. Zhang et al. modified the Needleman-Wunsch algorithm to quantify redundancy and investigate the redundancy patterns in outpatient clinical notes [13].

This work demonstrated that redundancy scores appeared to have a cyclic pattern for each individual patient but also that the overall volume of redundant information increased over time.

In this study, we investigated the use of statistical language models to identify clinically relevant new information in progress notes during patient hospital stays, applied a number of discounting models to potentially improve performance of the applied language models, and sought to compare the quantity of redundant information in clinical notes between inpatient and outpatient clinical settings.

Background

N-gram model

Statistical language modeling (SLM) is widely used for many NLP tasks, such as part-of-speech tagging, parsing, information retrieval, and machine translation [14, 15]. SLM assigns a probability to a set of *n* words based on a probability distribution from a specific corpus. An *n*-gram model is a typical language model (LM), which estimates the probability of an *i*-th word in the context of *n* previous words. To simplify the calculation of the probability of the word, the *Markov assumption* states that the probability of the word is only based on the prior few words instead of all previous words. One commonly used statistical estimate called Maximum Likelihood Estimates (MLE) is unsuitable for statistical inference in NLP due to the sparseness of the data. MLE assigns zero to unseen events, and the zeros will propagate since the probability of a long string is computed by multiplying probabilities of subparts.

Discounting methods

Discounting is the process of replacing the original counts with modified counts based on the mathematic formula to redistribute the probability in order to avoid assigning zero probability to unseen events due to the sparseness of the training sample texts [14, 15].

The simplest one is Laplace smoothing (also called add-one method):

$$P_{Lap}(w_1 \cdots w_n) = \frac{C(w_1 \cdots w_n)+1}{N+B}$$

where $C(w_1 \ldots w_n)$ is the count of the *n*-gram $w_1 \ldots w_n$, N is the number of training instances, and B is the vocabulary size.

The Good-Turing (GT)[a] estimator is an improved method for determining the probability or frequency of *n*-grams*:*

$$if\ 1 \le C(w_1 \cdots w_n) \le gt\max,\ P_{GT}(w_1 \cdots w_n) = \frac{C(w_1 \cdots w_n)}{C(w_1 \cdots w_{n-1})} \frac{C'(w_1 \cdots w_n)/C(w_1 \cdots w_n) - A}{(1-A)}$$

$$where\ C'(w_1 \cdots w_n) = (C(w_1 \cdots w_n)+1)\frac{n[C(w_1 \cdots w_n)+1]}{n[C(w_1 \cdots w_{n-1})]},\ A = (gt\max+1)\frac{n[gt\max+1]}{n[1]}$$

where $n[a]$ is the notion for the number of unique n-grams that occurred *a* times. This smoothing method substitutes low frequency *n*-grams and is quite accurate. It is also suitable for large numbers of observations of data and assumes that the distribution is binomial. The GT estimator works well for *n*-grams, despite the fact that words and *n*-grams do not follow a binomial distribution.

Ney and Essen proposed a linear discounting model for estimating frequencies of *n*-grams:

$$if\ C(w_1 \ldots w_n) = r,\ P(w_1 \ldots w_n) = \begin{cases} (1-\alpha)r/N & if\ r > 0 \\ \alpha / N_0 & otherwise \end{cases}$$

where α is a constant slightly less than one.

[a] http://www-speech.sri.com/projects/srilm/manpages/ngram-discount.7.html

These estimates make the probability of unseen events a small number instead of zero and rescale the other probabilities to ensure that the probability mass is equal to 1.0. However, the Ney and Essen linear discounting method does not work as well for higher frequency *n*-grams. In this study, we directly tested the use of these three discounting methods for building language models as part of our method evaluation.

Methods

Data Collection

EHR notes were retrieved from University of Minnesota Medical Center affiliated Fairview Health Services. For this study, we randomly selected patients in the inpatient clinical setting. These notes were extracted in text format from the Epic™ EHR system[b] during a one-year period (05/2011 to 05/2012). For simplicity, we limited the notes to the progress notes authored by the primary team providers including physicians, residents, and advanced practice providers (including physician assistants (PA) and nurse practitioners (NP)). All notes were arranged chronologically for a given individual patients. Institutional review board approval was obtained and informed consent was waived for this minimal risk study.

Manually reviewed annotation as gold standard

Each series of in-patient notes starts with the patient's history and physical (H&P) note, followed by a set of progress notes, and ending with a discharge summary. Starting from the progress notes in a series of patient notes, two 4th-year medical students were asked to identify new and clinically relevant information based on all preceding documents chronologically within the same hospital stay using their clinical judgment. Each medical expert annotated progress notes from ten patients with one patient's set of notes overlapping with both. Annotation of new information in clinical notes was implemented through the publically available software General Architecture for Text Engineering (GATE)[c]. GATE allows for annotation of text and XML outputs through a graphical user interface, with a customized annotation schema.

We first asked the two medical students to annotate one sample note and then to compare and discuss the annotations with each other to reach a consensus on the annotation categories and standards for new information (definitions and examples shown in Table 1). Each medical student later manually annotated another one set of patient notes based on the same historical notes to measure inter-rater agreement. Cohen's Kappa statistic and percent agreement were used to assess inter-rater reliability at a sentence or statement level.

Overall, longitudinal inpatient clinical notes from 20 sets of patient notes were annotated for this study. Each medical student annotated 50 notes, with a total of 100 annotated progress notes in this study. Fifty of these notes were used for training and system development and another fifty for evaluation. We also asked a 6th-year surgical resident (JL) with clinical practice experience to proofread the annotated notes, particularly around the addition of diagnostic studies (such as radiology reports) and make modifications to ensure the quality of the gold standard. We refereed annotations before and after JL's modification as initial annotation and revised annotation, respectively.

Results of automated methods were compared to the reference standard (initial annotation and revised annotation) and performance reported including accuracy, precision, recall, and F1-measure at a sentence or statement level. Methods were also evaluated comparing redundancy by different author role. For example, measuring redundancy of notes written by physician and residents as well as notes by physician assistants and nurse practitioners. Performance of the best method on identification of new information for different note sections was also tested.

Table 1. Classification, definition and examples of new clinical information.

Category	Code	Definition	Example
Clinical	Additional history	New information on patient's medical history occurring prior to hospitalization including prior diagnoses, surgeries, labwork/imaging, immunizations, medications, allergies/reactions, family history, and social history (e.g. sexual history, drug use, intake, work history, hobbies, marital status)	Recently admitted elsewhere for a pneumonia.
	Assessment	Changes in the medical diagnosis or differential diagnosis regarding patient's hospitalizing condition as assessed by the note's author	I am thinking this was all related to RF and CHF exacerbation.
	Changes in symptoms	Changes in patient reported symptoms including new complaints or improvement or worsening of existing concerns.	He says he is breathing better.
	Medications	Changes in medication, dosage, or route of administration including returns to pre-hospitalization usage. Also includes changes in fluids/electrolytes/nutrition administration and immediate post-administration clinical status.	Metoprolol 100 mg po bid changed to carvedilol 25 mg po bid
	New imaging and diagnostic studies	Results of imaging previously unmentioned during hospitalization such as X-rays, computerized tomography (CT scans), and solography.	TTE shows grade III diastolic dysfunction with elevated RSVP indicating pulmonary hypertension
	New labwork	Results of labwork previously unmentioned during hospitalization such as the basic metabolic panel, liver function tests, and blood glucose levels. Also includes fluid intake and output.	Wound cx: Gram + cocci UA shows a protein level of 300
	New plan	Changes in clinical care plan for patient care	Send sample for C. Diff studies
	Patient status	Changes in the patient's condition as reported by any healthcare provider	Perhaps a little improved today
	Physical exam	Daily physical examination as performed by clinician	Constitutional: Awake, alert, cooperative, no apparent distress
	Procedure	Procedures performed during hospitalization and related post-operative concerns	C2-4 laminectomy
	Vitals	Daily vitals including temperature, blood pressure, heart rate, and respiratory rate.	Temp: [98.1 F (36.7 C)-99F (37.2 C)] 98.2 F (36.8 C)
Non-clinical	Author	Name and degree of the note's author if previously unmentioned	LastName, FirstName, MD
	Change in service	Patient transfer to other hospital services or clinical sites	Patient will go to 6A for close Neuro-surgical monitoring.
	Date and time	Date and time of note signing by the original author	08/03/12 1148
	Social context	Changes in social history and situation relevant to the patient's condition and care including patient's preference to management	Dialysis discussed with patient, he prefers to wait until July.

Automated methods

We used different *n*-gram models with and without discounting algorithms. We only focused on bigram models since our prior studies[16] have showed the bigram models outperformed than other *n*-gram models. The methods include six steps: 1) text preprocessing, 2) removal of classic stopwords[d] and term frequency - inverse document frequency (TF-IDF) stopwords, 3) lexical normalization, 4) baseline modeling, 5) modification with discounting algorithms, and 6) application of heuristic rules to classify clinical relevance. The details of these steps are as follows:

Step 1: All progress notes were ordered by time for individual patients and were separated into sentences or sections. We used regular expressions for sentence splitter and word tokenization.

Step 2: Remove both classic stopwords and stopwords defined by optimal threshold of TFIDF distribution based on the entire note corpus. This step deemphasizes these less important words for building the language models.

Step 3: Use lexical variant generation (LVG)[17] to normalize lexically different forms of the same term as equivalent when building the language models.

Step 4: Bigrams were counted in all previous notes for each individual patient. Probability of the bigrams without discounting algorithms was calculated and an optimal threshold value was used to identify new in the target progress notes.

Step 5: Discounting algorithms such as Laplace, Good-Turning, and Ney-Essen (details in Background) were used to calculate the probability of bigrams. An optimal threshold probability value was used to identify new versus redundancy information.

Step 6: Develop heuristic rules to judge the clinically relevance on section content, clinical note headers, signatures. For example, vitals in all notes are judged as relevant new information. All note headers and footer are non-relevant information.

Comparison of information redundancy between inpatient and outpatient notes

To investigate the difference of redundancy in outpatient and inpatient clinical notes, we calculated the information redundancy based on the reference standards using the below equation:

$$\text{Redundancy percentage} = 100 \times \left(1 - \frac{\#\text{ sentences with relevant new information}}{\#\text{ sentences}}\right)$$

Note that the medical experts and residents only annotated the new and clinically relevant information. Thus non-clinical new information such as header of the notes, signatures *etc*. was excluded. Averages, standard deviations, interquartile ranges of redundant and irrelevant information percentages for clinical notes in different clinical settings and note types were calculated.

Results

Annotation evaluation and method performance

Two medical students showed a good agreement on initial set of annotations for identifying new information in the overlapping annotations (Cohen's Kappa coefficient of 0.83 and percentage agreement of 92%). On subsequent review, JL found additional new information (average 3.80 sentences per note) and incorrectly annotated information (average 0.07 sentences per note). This resulted in two reference standards – the initial and the revised one. The performance characteristics of various algorithms on both reference standards are listed in Table 2. Generally, all discounting methods performed better than the baseline, although three discounting algorithms did not change significantly. Compared with revised annotation, the methods' precision increased significantly with small drop in recall. Recall of methods in notes written by advanced practice providers were higher than notes by physician or residents, while the precision was much lower. The bigram model with the Ney-Essen algorithm performed the best among these methods, achieving a recall of 0.832, a precision of 0.743, and F1-measure of 0.784 for all notes after JL annotation.

Performance on identification of new information in different sections

Percentages of new information identified based on the revised annotations and separated by section, are also shown in Table 3. Top three sections with most new information are Physical Exam (33%), Assessment & Plan (27%), and Medication (14%). Performance of the best method (Ney-Essen algorithm) was also evaluated in different sections. Recall of this discounting method in the Medication section was the highest, and precision and F1-measure in the Vitals section were the best.

Table 3. Identification of new information in different sections on revised annotation.

Sections	Percentages of new information in notes	Recall	Precision	F1-measure
Physical Exam	33%	0.860	0.820	0.839
Assessment & Plan	27%	0.910	0.612	0.732
Medication	14%	0.982	0.764	0.859
Vitals	10%	0.939	0.957	0.948
Imaging	5%	0.723	0.933	0.815

Redundant and irrelevant information in inpatient versus outpatient clinical notes

Statistical descriptions of information redundancy for clinical notes are listed in Table 4. It is surprising that outpatient clinical notes contain redundant information at the same level (about 76%) as those in inpatient clinical notes. Notes written by advanced practice providers contain more redundant information than those by physicians and residents. Notes written by physicians had a smaller arithmetic mean and a larger standard deviation of redundancy than the notes by residents, fellows, and advanced practice providers.

Table 4. Redundant and irrelevant information for different clinical settings. PA, physician assistant; NP, nurse practitioner. Redundancy includes the non-clinical but new information.

Clinical Setting	Author Type	# Notes	Redundancy/irrelevancy mean (standard deviation)	Redundancy/irrelevancy (interquartile range)
Inpatient	All	100	76.6% (17.3%)	(70.6%, 87.9%)
	Physician	57	73.3% (19.1%)	(63.0%, 86.8%)
	Resident or Fellow	15	84.4% (10.0%)	(66.3%, 87.3%)
	PA or NP	27	84.5% (7.3%)	(82.6%, 89.4%)
Outpatient	Physician	90	76.7% (14.0%)	(72.4%, 86.2%)

Discussion

Our investigation of patterns of relevant new information in the inpatient clinical practice highlights the issue of redundancy of clinical information in EHR documentation, which has been increasingly gaining the interest of clinicians and informaticians in recent years. Automated methods to accurately identify and visualize relevant new information represent a potential way to improve the clinicians' reviewing process. Although researchers have developed some preliminary methods to deal with redundancy, most previous evaluations do not include the clinicians' own judgments based on clinical experience as a gold standard and thus fall short in evaluating these methods. However, it is vital to include clinicians' views on redundant information for the development of the methods since they will be potential end users of any future system. In this study, we focused on the development of automated methods to identify relevant new information in inpatient clinical notes as well as evaluation for the methods by comparing with the reference standards annotated by the end users - clinicians.

Constructing a quality reference standard is an important but challenging task to support the development of robust automatic methods. We followed the same process as our previous study [18] for reference standard: smaller sample annotation, discussion to reach a consensus, and then larger sample annotation. Although the annotation code book (Table 1) was meant to help with consistency of our medical student coders, we still found that they missed new information and our modified standard improved the consistency of these annotations. For instance, in the original set of annotations, coders sometimes ignored the changes of current medication list, including addition of a new drug or discontinuation of a current medication ("DISCONTD: sodium chloride 0.9 % flush 10 mL" as an example), and the possible reason is that it is difficult to find small changes in a long and tightly laid out section, such as a medication section. Other disagreements were from the different identification of new information boundary. For example, one annotator included the section title (e.g, objective, exam, assessment and plan) as new information if there was new information within the section; another annotator chose not to identify the title of section as new information.

After comparing the results produced by automated methods with reference standards, we found that discounting algorithms help to improve the performance of the methods. All methods did not perform very well on precision as our methods were developed on the lexical level of the texts and did not consider the semantic meaning of the sentences. For example, the sentence "continue to hold all nephrotoxic meds" in the target note was not identified as redundant by comparison with the sentence "hold lasix, lisinopril and spironolactone given acute kidney injury" in a previous note. Due to the limitations of the methods, they cannot recognize that specific drugs such as lasix, lisinopril and spironolactone are nephrotoxic medications.

The text formats in different sections result in variability in performance on different sections. "Assessment/Plan" (A&P) is one of the longest sections in the notes, where clinicians input their thoughts and tend to rephrase sentences even for the same meaning from the previous notes. For example, in the above example, the physician typed "nephrotoxic medications" instead of specific medication names "Lasix, lisinopril and spironolactone". Thus, this probably is the main reason why the precision in the A&P section was the lowest. As for the Vitals section, the format is unique as "Temp: 97.2 °F (36.2 °C) | BP: 100/75 | Resp: 20…" in most notes, allowing the methods to easily recognize the pattern, resulting in a higher precision and recall compared with other sections. Similarly, the "Physical Exam" section usually contains the short statement for each part such as "General: Lying nearly flat in bed, comfortable, NAD, Interactive".

Analysis indicated a high level of redundant and irrelevant information in inpatient progress notes (average 76.6% for 100 notes), although we included the irrelevant note format or noise in this calculation. This number may be different if we were to consider a larger dataset. To our knowledge, there is no prior study reporting the percentage of redundant information in outpatient notes. Surprisingly, the redundancy in outpatient notes contains the same amount of redundant information. One reason for this is that we only selected chronically diseased patients, allowing the larger sets of longitudinal clinical notes for our previous study. Another reason is that all those notes for calculating redundancy in outpatient clinical setting were the last three notes from each set of individual patients. In our previous study [13], we found that the information redundancy of longitudinal outpatient notes was increasing over time. In other words, the last three notes tend to contain relatively higher redundancy than the earlier notes averagely. Therefore, the actual percentages of information redundancy for the entire set of outpatient notes could be lower than the reported number (76.7%) here in Table 3. In addition, we observed that advanced practice providers had higher levels of redundancy and less variability in this (lower standard deviation) than physicians. While it is unclear why this was the case, we speculate that physician providers have more diagnostic and case-based reasoning in notes with significant clinical events, and advanced practice providers are more prescriptive in their narrative. Future studies are needed to both confirm these findings on a larger corpus, as well as perform an analysis of why these differences may exist.

Our methods have certain limitations. All methods focused only on the lexical level. Semantic level issues were out of the scope of this paper, such as co-reference (e.g., "it", "this") and experiencer detection (e.g., "patient", "sister"). For example, "Pt has diabetes" and "His mother has diabetes" shared most of the words, but they are semantically different as the experiencers are changed. Acronym and symbol disambiguation were also not included in the study. Moreover, relevant new information was only limited to the addition of information in the newer notes. The deletion of relevant new information in the more recent clinical notes was not considered in this study. Due to the asymmetric nature of the new information identification process, deletion of relevant information can only be obtained by comparing the object notes and target note in reverse and warrants additional investigation. Future research will add more semantic components to make the system more accurate and comprehensive, and design the ways to visualize the relevant new information by incorporating within existing EHR systems. This implementation will ultimately enhance the efficiency of reviewing and using clinical documentation, and improve the satisfaction of clinicians with EHR systems.

Conclusion

We developed language models with discounting algorithms to identify relevant new information in inpatient progress notes, and evaluated the performance by building up and comparing with a medical expert-derived reference standard. Inpatient clinical notes have approximately the same amount (76%) of redundant or irrelevant information as outpatient clinical notes. Further investigation is needed to improve the performance of the system and visualize the information in EHR systems to enhance the efficiency of using clinical documentation.

Developing Analytical Inspection Criteria for Health IT Personnel with Minimum Training in Cognitive Ergonomics: A Practical Solution to EHR Improving EHR Usability

Zhen Zhang, MD, MPH, MSc, Amy Franklin, PhD, Muhammad Walji, PhD, Jiajie Zhang, PhD, Yang Gong, MD, PhD

Abstract

EHR usability has been identified as a major barrier to care quality optimization. One major challenge of improving EHR usability is the lack of systematic training in usability or cognitive ergonomics for EHR designers/developers in the vendor community and EHR analysts making significant configurations in healthcare organizations. A practical solution is to provide usability inspection tools that can be easily operationalized by EHR analysts. This project is aimed at developing a set of usability tools with demonstrated validity and reliability. We present a preliminary study of a metric for cognitive transparency and an exploratory experiment testing its validity in predicting the effectiveness of action-effect mapping. Despite the pilot nature of both, we found high sensitivity and specificity of the metric and higher response accuracy within a shorter time for users to determine action-effect mappings in transparent user interface controls. We plan to expand the sample size in our empirical study.

Introduction

Electronic health record systems (EHRs) are the most critical form of IT penetration in the healthcare system. Being increasingly integrated across every aspect in healthcare delivery, EHRs are expected to be the powerful means to optimize quality of care. However, the National Research Council reported that current health IT applications provide little support for clinicians' cognitive tasks, increase the chance of error, and add to rather than reduce workload due to underutilization of human-computer interaction (HCI) principles [1]. Although usability, or human factors, has been widely recognized in the medical device industry since 1988 [2], it is currently a big challenge to improve the usability of complex EHRs.

Several differences between the medical device industry and the EHR industry shed light on practical solutions to the EHR usability challenge. First, unlike the former with human factors design process addressed in the American National Standard [3], AMIA Usability Task Force identified barriers in the EHR industry to adopt user-centered design process, such as different user types in one organization and significant process variations across different organizations [4].

Second, designing and evaluating EHRs become more complicated in organizations that are developing safer and more efficient processes. The uncertainty as to the fitness of EHRs for complex socio-technical systems coincides with the uncertainty of radical transformation in the organizations. A viewpoint from research scholars beyond the healthcare arena attempts to tackle such technology-and-institution co-evolving phenomena by engaging two fields --- IT research and organization studies --- in conversation [5].

Third, unlike ready-to-use medical devices delivered to the market, EHRs often require a significant amount of configuration made by local health IT personnel, especially for large healthcare systems. The functioning EHR that clinicians interact with is in fact the joint effort by the EHR vendor and the local IT department. Different from medical device manufacturers being held accountable for usability from early design phase [6] to post-market surveillance [7], it is yet not clear which entities should take the responsibility for improving EHR usability.

Last, unlike medical device manufacturers with established human factors programs and designated staff, healthcare organizations lack IT personnel with the expertise in usability engineering and usability evaluation. EHR analysts in healthcare organizations perform needs assessment, deliver ready-to-use EHRs, and directly support EHR use in

dynamic clinical and organizational contexts. However, only technical skills on EHR configuration and trouble-shooting in combination with a good understanding of clinical needs are currently required for this job role.

Due to the above usability challenges in the EHR world, practical tools that can be operationalized by IT personnel with minimum training in usability are in urgent demand. Healthcare organizations need to be the key players on assuring EHR quality use in dynamic contexts. Among numerous usability evaluation methods, analytical inspection is the efficient approach to screen for low-level predictable usability problems on end user interfaces (UIs). Since the scope of EHR configuration is often limited to textual labels of UI controls, cognitive ergonomics issues should be the first priority for healthcare organizations. Cognitive ergonomics focuses on the understanding of human cognitive abilities and limitations in the contexts of work in order to "improve cognitive work conditions and the overall performance of human-machine systems".[8] The goal of this research is to develop a set of reliable and valid inspection criteria for EHR analysts without systematic training in cognitive ergonomics.

Background

Usability is a multi-faceted concept in the quality model in ISO 25010 Software Quality Requirements and Evaluation (SQuaRE) and in the definitions published by research scholars [9, 10]. In spite of different opinions on usability components and measures, whether user interfaces (UIs) are easy for users to learn to use is one of the few in agreement. Clinicians highly desire EHRs that they can easily figure out how to use due to the time-pressured and interruptive work environment.

Analytical Inspection

Usability evaluation methods vary in the scope, theoretical basis, input, and output. Those that do not require user observation as the input during the evaluation are classified as analytical methods. Some are based on mathematical models such as GOMS model [11]; others are not and are generally referred to as *analytical inspection,* including heuristic evaluation [12], expert review, and cognitive walkthrough [13]. While saving a substantial amount of resources on collecting raw data from users and analyzing them, analytical inspection has limitations on the scope of usability issues being detected and evaluator effects [14].

In the effort of comparing different analytical inspection methods, a set of criteria based on the quantity of usability problems detected were proposed [15]. However, depending on the theoretical basis, these methods vary in the scope of targeted usability problems, and the concept of usability itself consists of multiple facets in very different nature. Simply using problem count as the indicator to compare inspection methods has been criticized [16].

A more helpful guidance for usability practitioners is to distinguish the scope of each method, that is, "what kinds of usability problems a method is and is not good for finding" [17]. Criteria based on the characteristics of the method, including reliability, validity, and downstream utility, are meaningful parameters for method evaluation. Reliability is the extent to which same input can yield same output regardless of the evaluator who applies the method, that is, there is very little evaluator effect [17]. Validity is "the extent to which the findings from analyses conform to those identified when the system is used in the 'real world'' [17]. Downstream utility describes the usefulness of the findings in informing redesign [17]. Downstream utility is especially important for analytical inspection methods because the ultimate goal of early-stage usability evaluation is design improvement.

Heuristic evaluation is a widely adopted inspection method. However, it relies on a limited set of loosely defined principles, which results in significant evaluator effect or low reliability across evaluators [14]. A method with low reliability means that the quality of its findings is highly inconsistent.

Cognitive walkthrough is an inspection method based on a cognitive model that guides evaluators through users' cognitive activities while performing tasks in "walk-up-and-use" applications (i.e. those that can be used with little training). In spite of the more structured evaluation procedure, usability problem detection is still subject to the evaluators' experience. Its focus on evaluating "the ease with which a user completes a task with minimal system knowledge" [18] makes it especially important to EHR usability.

The inspection criteria under development in this research are based on the same theoretical foundation as cognitive walkthrough and the goal is to improve the reliability and validity of usability inspection when the method of

cognitive walkthrough is employed. The inspection criteria are intended to provide guidance on identifying usability issues that make it difficult for users to figure out how to complete tasks, which will be further described in the following section.

Theoretical Foundation

To specify the different types of issues within this general scope and explain the theoretical basis of the proposed inspection tool, an overview of the resource model from the HCI field is provided here. The resource model explains how users figure out how to interact with UIs. The term *resource,* or task-critical information, is defined as the information that can be utilized by users to make interaction decisions [19]. The information on the UIs not only constrains what actions are possible but also helps users decide which action to take in order to accomplish their goals [20].

Users' interaction strategy varies depending on the available *resources* in the specific scenario [19]. *Plan following* strategy requires a pre-defined sequence of actions (i.e. *plan*), which is usually developed through systematic training. However, when there is adequate information on the UIs, users can figure out each action responsively without a pre-defined plan, which saves the mental cost of constructing and executing a plan. This less costly interaction strategy is named as *goal matching*. By matching the effect of a possible action with the current goal, users make interaction decisions without advance planning [19].

Table 1. Resource categories defined in the resource model [20]

Resource Category	Definition
Goal	A desired state of the world
Current state	A collection of attributes used to judge whether the state is closer to the goal
Plan	A pre-defined sequence of actions
Action possibility	Whether an action can be made or not
Action-effect mapping	Link between an action and its effect that will take place after the action is executed
Interaction history	A list of already-taken actions

The resource model reveals the association between *resource* category and interaction strategy. It provides a general guidance on how to determine what *resource* should be made readily available on the UIs in order to facilitate an interaction strategy. However, this theory fails to provide an operationalizable tool to determine whether or not task-critical information is effectively presented on user interfaces. If certain task-critical information is not effectively presented on the user interface, users have to retrieve that information from their memory, which incurs unnecessary cognitive effort.

As to EHRs, low cognitive effort of figuring out how to use is strongly desired because clinical documentation and business operations should not be an additional burden to clinicians' working memory which is already reaching its limit due to the high demand on productivity and safety in a work environment full of interruptions. According to the resource model, action-effect mapping is the key task-critical information that makes the less costly strategy *goal matching* feasible for users. Therefore, the analytical inspection criteria are developed particularly to provide guidance on how to determine whether or not action-effect mapping is effectively presented on user interfaces.

Methods

Preliminary Study

Initially, a metric for cognitive transparency was developed as a tool to guide the inspection of EHR user interfaces (UIs) for ease of use and ease of learning. As shown on Figure 1, the concept of cognitive transparency refers to clear representation of both operations and object-operation relations on UIs so that users can understand what will happen at the work domain level if they click on the UI controls. If the operation of the work that will be accomplished using the UI control is clear on the UI, the operation is considered as being externally represented according to the distributed cognition theory [21, 22]. If the operation is not clear on the UI and requires prior

knowledge in the user's mind, it is considered as being internally represented. Same applies to object-operation relation. When both of the operation and object-operation relation are externally represented on the UI, the UI control is considered as cognitively transparent. The concepts of operation, object, internal representation, and external representation will be illustrated using concrete examples given on Figure 2.

Metric for Cognitive Transparency		Representation of Object-Operation Relation	
		External (clear on the UI)	*Internal (memory required)*
Representation of Operation	*External*	**Transparent**	Not Transparent
	Internal	Not Transparent	Not Transparent

Figure 1. Initially proposed analytical approach: metric for cognitive transparency

On the top of Figure 2, the UI control with the textual label "Edit" is located next to a medication. Clicking "Edit" enables the user to edit that particular medication, where edit is the operation of the work that will be accomplished by clicking "Edit" and the particular medication is the object. In this case, both of the operation and object-operation relation are effectively presented on the UI, or externally represented. The UI control is cognitively transparent. On the bottom of Figure 2, the effect after clicking the UI control with the label of a medication name is not presented at all on the UI. It requires the user to have prior knowledge about the actual effect of this action. In this case, the object is the medication which seems clickable; however, the operation of the work that will be accomplished by clicking the medication name is internally represented. Thus this UI control is not cognitively transparent.

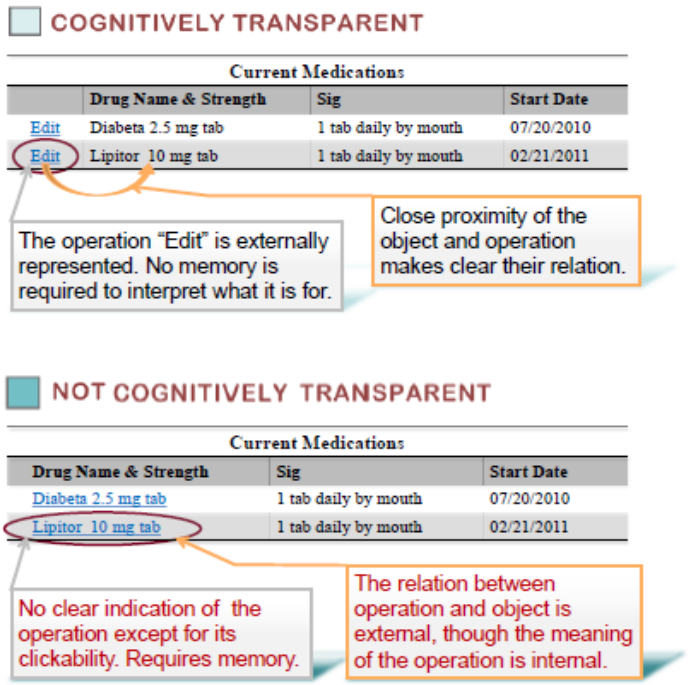

Figure 2. Examples of clickable user interface elements

The validity of this metric was tested in this preliminary study. One evaluator applied the metric to a set of clickable UI controls to predict if they are cognitively transparent or not. The UI controls were selected from E-Prescribing Use Case in three ambulatory EHRs. Three participants with general computer experience were recruited. With the original EHR screenshots presented, participants were asked to anticipate work domain effect of clicking the

selected UI controls, that is, "what do you think will happen in terms of the work that you are doing if you click this". Participants' anticipations were compared to the actual work domain effect of clicking those controls in the live EHRs. If the anticipations from all of the three participants match the actual effect, the UI control was empirically classified as cognitively transparent. If the anticipation from at least one participant does not match the actual effect, the UI control was empirically classified as not cognitively transparent. Subsequently, the predictions made using the metric were compared with the classification based on participants' anticipations. The specificity and sensitivity of the metric were analyzed.

Exploratory Experiment

Based on this initial metric, a set of inspection criteria were developed for health IT personnel with minimum training in cognitive ergonomics to identify issues of presenting action-effect mapping on UIs. According to the resources model, UIs where action-effect mapping is effectively presented are hypothesized to be easier for users to correctly match their goals with possible actions on the UIs.

The exploration for the validity of the inspection criteria on action-effect mapping began from UI controls that enable initiation of entry tasks. The proposed inspection criteria are explained in Table 2. Based on the proximity compatibility principle, the object can be directly presented on the label of the UI control or indirectly presented via immediate neighbor element(s). Published studies have demonstrated that unlabeled icons are significantly more difficult for novice users in all ages to interpret than textual labels [23]. Therefore, only texts or well-recognized symbols are considered as effective presentation.

An exploratory study was conducted to test whether user performance differs between EHR UI controls with effective presentation of action-effect mapping versus those without. Due to lack of published information on UI factors that affect human performance in relevant experiments, screenshots from several EHRs with multiple variations were used in this exploratory study.

Table 2. Proposed inspection criteria for EHR UI controls that initiate entry tasks

Effective Presentation*	**Location**	**Form**
Operation	On the same UI control	Text or symbol (e.g. "+" = add)
Object**	On the same UI control	Text
	Immediate neighbor	Text (usually as a header)
		View-only display of instances (e.g. a list of medications)

*A UI control is considered to be transparent only if both the operation and the object involved are effectively presented.
**The object is considered to be effectively presented as long as it falls in any of the three situations.

- *Stimuli*

A total of thirteen screenshots were extracted from four commercial EHRs. The work domain effects of selected UI controls were initiating prescription entry, initiating problem entry, initiating allergy entry, and initiating lab order entry. These screenshots were presented randomly to each participant via online first-click testing software Chalkmark (Optimal Product, New Zealand).

- *Participants and Procedures*

Four physicians with no prior exposure to these particular EHRs were recruited. During the experiment, they were asked to click on the presented screenshot to achieve a given goal. Prior to each screenshot being presented, one goal was indicated on the prompt, which corresponded to the work domain effect of the target UI control. An example prompt is "you would like to prescribe a medication (or order a laboratory test, etc.) to this patient. Where would you click to begin?". The location of their mouse click on each screenshot was collected together with the duration from the screenshot being presented to mouse click (i.e. response time).

- *Confounding Factors*

The variation in the quantity of textual words and pictorial icons on these screenshots was hypothesized to affect participant performance in addition to the independent variable in this exploratory study. The word count and icon count on each screenshot were analyzed with test patient data excluded.

Results

Preliminary Study

The percentages of UI controls with metric-derived prediction matching the empirical classification are presented on Figure 3. In EHR 1, among 35 target UI elements, 60% were predicted by the metric as transparent and had all of the three subjects' anticipations matching the work domain effect in the live EHR (i.e. empirically classified as transparent); 31% were predicted as not transparent and had at least one subject's anticipation not matching the work domain effect in the live EHR (i.e. empirically classified as not transparent); 6% were predicted as not transparent but empirically classified as transparent; 3% were predicted as transparent but empirically classified as not transparent. In EHR 2, among 17 target UI elements, 70% were predicted as transparent and empirically classified as transparent; 12% were predicted as not transparent and empirically classified as not transparent. In EHR 3, among 18 target UI elements, 50% were predicted as transparent and empirically classified as transparent; 39% were predicted as not transparent and empirically classified as not transparent.

		Observation from Experiment	
EHR 1 (total 35 UI elements)		Transparent (agreed by 3 subjects)	Not Transparent (at least 1 subject)
Prediction from Metric	Transparent	**60%**	3%
	Not Transparent	6%	**31%**
EHR 2 (total 17 UI elements)		**70%**	12%
		6%	**12%**
EHR 3 (total 18 UI elements)		**50%**	11%
		0%	**39%**

Figure 3. Proportions of UI controls with metric-derived prediction matching or not matching empirical classification

The specificity and sensitivity of the metric in each EHR are presented on Table 3. This preliminary study suggests that the cognitive transparency metric has high sensitivity and acceptable specificity.

Table 3. Specificity and sensitivity of metric for cognitive transparency

	Sensitivity	Specificity
EHR 1	91%	92%
EHR 2	92%	50%
EHR 3	100%	78%

Exploratory Experiment

Accuracy of response was determined by comparing the location of a participant's mouse click on the screenshot with the location of the target UI control. The small sample size (i.e. number of screenshots) in this exploratory

study makes it difficult to detect any statistical significance from the results. Basic data analysis was carried out to look for any potential difference in the two measures (i.e. accuracy of response and response time) between two groups of UI controls.

As shown in Table 4, the average accuracy of response for the group of UI controls with action-effect mapping effectively presented was 63%, whereas that for the group with action-effect mapping ineffectively presented was 33%. The average response time for the former group was 19 seconds, whereas that for the latter group was 28 seconds.

Table 4. Average accuracy of response and average response time for UI controls with effective or ineffective presentation of action-effect mapping

Presentation of Action-Effect Mapping	Number of Stimuli	Participant Performance		Average Word Count (Icon)
		Average Accuracy of Response	Average Response Time (seconds)	
Effective	10	63%	19	80 (30)
Ineffective	3	33%	28	75 (39)

UI controls with action-effect mapping effectively presented according to the proposed inspection criteria appeared to have a higher average accuracy of response with a shorter average response time. The average word count and average icon count were similar among the two groups of UI controls, suggesting that the quantity of words or icons may not be a contributing factor to the difference in participant performance.

Discussion

The EHR industry urgently needs HCI theories to be translated into inspection tools that can be operationalized by health IT personnel with minimum training in cognitive ergonomics, which empowers healthcare organizations to improve EHR usability and thereby assure EHR quality use in dynamic operational and clinical contexts.

Among different components of usability, clinicians strongly desire EHRs that are easy to figure out how to use without systematic training and memorization. Operating EHRs at the point of care should incur little unnecessary cognitive effort and clinicians' limited mental capacity should be focused on patient care. The theory-based criteria under development in this research are targeted at supporting analytical inspection of EHR UIs from this aspect.

Analytical inspection is the efficient approach to detecting low-level predictable usability problems because it does not require collection of raw data from user observation. The quality of findings relies on the theory basis of the inspection method or tool. Healthcare organizations can benefit the most from the HCI field by employing validated inspection tools in the EHR configuration process.

However, there is little agreement on how to empirically validate an inspection tool. The preliminary study and the exploratory experiment reported above are validation attempts using different research design. In the preliminary study, the target UI controls was pointed out on the screenshots presented to participants, and the raw data collected from participants were their anticipations of work domain effects after clicking those UI controls in live EHRs. In contrast, the exploratory experiment presented screenshots to participants without pointing out the target UI controls, but with specified goals that corresponded to the work domain effects of the target UI controls. The participants' choices of UI controls for the given goals were the collected empirical data. The research design in the exploratory experiment well simulated user interactions in the real world, compared to the preliminary study, thus will be adopted in future research on validating other proposed inspection tools.

Although objective performance measures, such as the location of clicking, are more robust indicators of the effectiveness of use than subjective measures, such as confidence rating, it is still important to include subjective measures in future research to understand participants' subjective perception with regard to the clarity of UIs. Other

UI factors that are different across EHRs and may affect human performance were not controlled in the exploratory experiment. A controlled experiment will be conducted in the future to establish the causal effect relationship between the effectiveness of action-effect mapping presented on UIs and participants' accuracy of response. Meanwhile, it is critical to expand the sample size so that statistical significance can be tested.

In addition to validity, reliability is another key criterion to evaluate inspection tools. Future research will test the reliability of the proposed inspection tools. Multiple evaluators with various levels of experience in usability will independently apply the inspection tools to detecting ineffective presentation of action-effect mapping on EHR UIs. Their detection results will be compared and analyzed statistically.

Abstract

The Worcester Heart Attack Study (WHAS) is a population-based surveillance project examining trends in the incidence, in-hospital, and long-term survival rates of acute myocardial infarction (AMI) among residents of central Massachusetts. It provides insights into various aspects of AMI. Much of the data has been assessed manually. We are developing supervised machine learning approaches to automate this process. Since the existing WHAS data cannot be used directly for an automated system, we first annotated the AMI information in electronic health records (EHR). With strict inter-annotator agreement over 0.74 and un-strict agreement over 0.9 of Cohen's κ, we annotated 105 EHR discharge summaries (135k tokens). Subsequently, we applied the state-of-the-art supervised machine-learning model, Conditional Random Fields (CRFs) for AMI detection. We explored different approaches to overcome the data sparseness challenge and our results showed that cluster-based word features achieved the highest performance.

Introduction

WHAS[1,2] is an ongoing population-based investigation examining changing trends in the incidence rates, hospital and post discharge death rates, occurrence of major clinical complications, and use of different management approaches in residents hospitalized with independently validated AMI at all metropolitan Worcester hospitals in Massachusetts. It has been used to study comparative change in attack and survival rates of AMI, the impact of age on the incidence and prognosis of initial AMI, etc, and has been contributing significantly to cardiovascular diseases population studies for decades. Various patient information has been collected, including demographics, medical history symptoms, laboratory and physiologic measures, medications, diagnostic procedures, coronary interventions, hospital length of stay, and hospital survival status.

Despite the large amount of data manually collected in the WHAS study, the data is not geared towards automatic information extraction from the clinical narratives. The assessment starts with the medical records of patients hospitalized with possible AMI in the dataset where clinicians manually review, validate, and extract information according to pre-defined diagnostic criteria. The corresponding text references in the medical records (or the annotation) were not recorded.

In this study, we report the preliminary development of supervised machine learning models for AMI information extraction from EHR DSs. We developed annotation guidelines and reported inter-annotator agreement. With an annotated EHR DSs data, we developed natural language processing (NLP) systems for automation of case validation of, and data abstraction from, EHR of patients hospitalized with AMI.

Our main goal is to develop and evaluate a machine-learning based NLP system to automatically extract AMI related information to facilitate AMI manual review. Our major contributions are the following:

a. We built an EHR-based guideline for annotating diagnostically relevant AMI variables including acute symptoms and electrocardiographic (ECG) and laboratory findings.

b. Although EHR annotation is not new, we are the first group to report the annotation and excellent inter-annotator agreement of AMI information using EHR DSs.

c. We are the first group to report automated AMI detection from EHR DSs. In our supervised machine learning approaches, we explored cluster-based learning features, which have not been widely used in clinical NLP tasks, and found that the features improved the performance.

Related Work

Concept identification has been a key NLP task since its inception. In the biomedical domain, many NLP systems have been developed to extract concepts based on the rich resources provided by the Unified Medical Language System (UMLS)[3] from unstructured clinical narratives. MetaMap performs lexical and syntactic analysis on input text and phrases are mapped to the UMLS concepts[4]. MedEx recognized medication information, such as drug name, dose, frequency, route, and duration[5]. cTAKES analyzes clinical free text using models specifically trained for the clinical domain and maps phrases to the UMLS concepts with additional attributes such as negation, uncertainty, and conditional, etc[6]. KnowledgeMap is a collection of NLP tools for clinical text[7], one of which is the Concept Index tool which identifies biomedical concepts and maps them to the UMLS. ARC aims at building a generic platform of information retrieval without custom code or rule development by the end user. It automates feature (including concepts extracted by cTAKES) and algorithm selection using existing medical NLP tools[8].

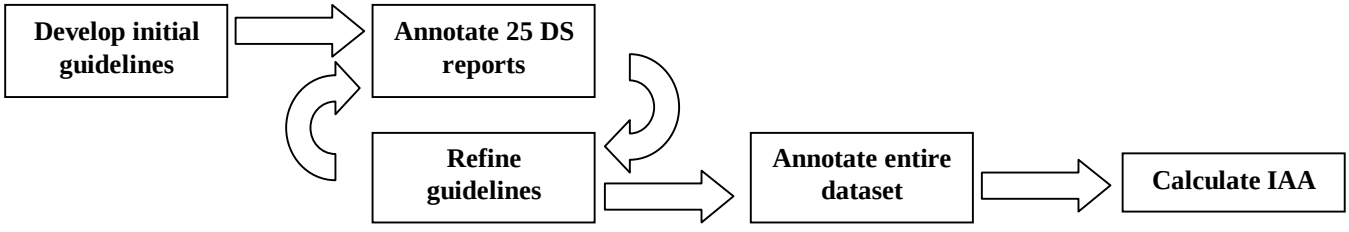
The Center of Informatics for Integrating Biology and the Bedside (i2b2) organized challenges to extract clinical entities, including medication[9] and problems, tests, and treatments[10] from EHR narratives. In the 2010 challenge, it has shown that supervised machine learning systems performed well for extracting medical concepts (problems, treatments, and tests) from EHR narratives, from which CRF models[11] stand out being the most successful models[12–14]. Features commonly used in these models include lexical and morphological features (word form, prefix/suffix), grammatical features (parts of speech), and semantic features (concepts extracted using rule-based approaches). Ensemble methods that combine multiple CRF-based and other rule-based models also showed success in this task[15].

Rule-based approaches are fast to deploy. However, for a focused domain such as AMI, a general-purpose tool would extract much more information than necessary, thus requiring careful filtering or building and tuning the rules. Therefore, we designed a supervised machine learning based system. Annotated data is essential for supervised machine learning. Although the biomedical annotation efforts have been deep and wide,[16] we are not aware of studies that annotate named entities for AMI. With the approval from the Institutional Review Board of the Medical School of the University of Massachusetts, we conducted annotation and NLP development for automatically recognizing AMI information.

Material and Methods

Pre-defined diagnostic criteria are key information in the WHAS database. These criteria include a clinical history of prolonged chest pain not relieved by rest or use of nitrates, serum levels of various biomarkers in excess of the upper limit of normal as specified by the laboratory at each greater-Worcester area hospital, and serial electrocardiographic tracings during hospitalization showing changes in the ST segment and Q waves typical of AMI. At least two of these three criteria need to be satisfied for study inclusion. Cases of perioperative-associated AMI are not included in the study sample. However, these criteria appear mainly in the narrative text of discharge summaries (DS), not in the structured data. Since there is no annotation at the word level in the discharge summaries, we first developed the annotation guidelines. The discharge summaries are then annotated by two annotators according to these guidelines. This process is illustrated in Figure 1. In the following we first describe the annotation guidelines and then report inter-annotation agreement, and our NLP approaches.

Figure 1. Illustration of the annotation process.



Data

We obtained a set of 105 discharge summary reports by filtering the reports that contain the ICD-9 diagnostic rubric 410 (AMI) as the primary or secondary discharge diagnosis. Five types of entities are annotated in these reports: symptoms, ECG findings, lab observations, ICD diagnosis, and Catheterization lab findings. These entity types are

validation criteria to rule in patients as AMI cases, which were developed by the World Health Organization[1], and more recently, by the Third Global MI Task Force[17].

Annotation Guidelines

The annotation guidelines were developed by a physician, a linguist, and three biomedical informaticians through an iterative process. Following the initial version of the annotation guidelines, two annotators first independently annotated 25 DS reports, and then resolved the disagreements. The guidelines were revised to reflect the discussions during the consensus session. Table 1 shows the annotation guidelines for the five entity types.

Annotation Process

An expert physician designated as *AnnPhy*, annotated 105 DS reports, including the 25 reports used to develop the guidelines. A linguist, designated as *AnnLing*, also annotated the same 25 reports. The inter annotator agreement was calculated using the 25 reported independently annotated. The annotated corpus was used to build machine-learning models to identify the AMI information. There were a total of around 135K word tokens in the corpus of 105 DS reports with an average of 1285.6 ± 440.5 word tokens per report. The subset of 25 reports consists of a total of 29.5K word tokens with an average of 1178.2 ± 377.0 word tokens per report. We report the Cohen's κ[18] to calculate the IAA between annotators.

Table 1. Definitions and examples of annotation categories.

Entity type	Definition	Select examples
Symptoms	Presence of symptoms of myocardial ischemia	Abdominal pain, chest pain, nausea, vomiting, shortness of breath
ECG Findings	Acute or evolving changes in the ST-T wave forms and Q waves, Bundle branch block	Q wave MI, T wave inversions, New LBBB
Lab Observations	Biomarker/cardiac enzyme detection of myocardial injury with necrosis	Cardiac enzymes, Elevated troponins
ICD diagnosis	ICD9 discharge diagnosis	410 Acute myocardial infarction, 410.00 episode of care unspecified
Catheterization Lab Finding	Description/Mention of AMI	Location of AMI (e.g., anterior, inferior, posterior, lateral)

Supervised Machine Learning Approaches

We developed a supervised CRF models to identify the clinical entities as shown in Table 1. CRFs are widely used in various NLP tasks, and have been shown to be among the best models for NER[10]. CRFs predict entity types from a sequence of input word tokens by optimizing for the conditional probability of the label given the observed data.

We used the ABNER[19] package as our CRF implementation. The features in this implementation include word token, word type, punctuation, capitalization, prefix, suffix, roman letters, and features from the previous and following words. We trained our systems to predict the symptoms, ECG findings, Lab observations, and ICD diagnosis entities. Catheterization lab finding is excluded because it is very rare in our dataset.

Our basic CRF implementation only utilizes lexical and morphological features. To explore the effects of various features on the data, we incorporated both syntactic (part of speech tags) and semantic (word representation) features into this basic CRF model as additional features. The parts of speech are obtained using the maximum entropy based classifier from OpenNLP with a model trained with both general English and clinical text[6] (including GENIA, Penn Treebank and anonymized medical records).

Each word in a corpus is conventionally represented as one dimension in the feature vector. Thus, the feature vector has the same length as the vocabulary size. Parameters for the rare words are poorly estimated from the data. It can not handle new words in the test data either. Word representation features can overcome this data sparseness problem. We explored two types of word representation features. The Brown cluster-based approach represents words in a hierarchical cluster, which maximizes the mutual information of bigrams. We learned Brown clusters from a collection of approximately 100,000 clinical notes (46 million tokens), including discharge summaries,

cardiology reports, emergency notes, history and physical exams, operative reports, progress notes, radiology notes, and surgical pathology notes. To compare with word representations induced from general English text, we also trained a CRF model with Brown clusters from the RCV1 news corpus[20,21] (approximately 810,000 news stories) provided by Turian et al[22].

The other approach to overcome data sparseness is to induce word embeddings. This approach represents a word as a dense low-dimensional vector. These dimensions capture latent features of the words. Word representation features have been shown to improve performance in NLP tasks including chunking and entity recognition. In our system, we incorporated a word embeddings representation included in SENNA[23] that was learned from English Wikipedia text.

Results

Corpus Characteristics and Annotator Agreement

Table 2 below shows the characteristics of the data: entity types, the number of entities annotated in each category and the inter annotator agreement in terms of Cohen's κ. We report both strict κ, where there is an exact match between the entities annotated and un-strict κ, where there is at least one word token overlap between the annotated entities. *ECGFindings* had the highest strict κ value of 0.86 followed by *LabObservation* with κ value of 0.84. Whereas, *LabObservation* achieved the highest un-strict κ value of 0.98 followed by *ECGFindings* with a κ value of 0.95 for un-strict criteria. Overall, all the entities except for *CatheterizationLabFinding* achieved a strict κ of over 0.74 and an un-strict κ of over 0.9. Since *AnnPhy* annotated only one entity in *CatheterizationLabFinding* category, the κ value was low for *CatheterizationLabFinding*. Both strict and un-strict F1 scores are reported as well.

Table 2. Annotated named entities, number of instances, and inter-annotator agreement.

Entities	AnnPhy		AnnLing	κ (strict)	κ (un-strict)	F1 (strict)	F1 (un-strict)
	Number of entities		Number of entities on 25 reports				
	25 reports	105 reports					
Symptom	153	651	244	0.74	0.93	0.36	0.71
ECG Findings	75	368	64	0.86	0.96	0.68	0.83
Lab Observations	105	370	66	0.84	0.98	0.20	0.61
ICD diagnosis	15	60	41	0.75	0.96	0.18	0.44
Catheterization Lab Finding	1	1	3	0.13	0.76	0.00	0.50

Experiment Results

We report recall, precision, and the F1 score using 10-fold cross-validation. Table 3, system setting b shows the performance of our basic CRF model using only the lexical and morphological features from ABNER. As a baseline, we implemented a rule-based method that matches terms defined in the annotation guidelines. Since only AMI related entities are considered, a general dictionary lookup system such as MetaMap will produce a large number of irrelevant entities---only 12% of the entities of type symptom, findings, lab results, and lab procedures from MetaMap appear in the annotation guidelines. The results of our baseline are shown in Table 3, system setting a. The results show that the rule-based dictionary-lookup has the worst performance in all five categories. The overall F1 score using the dictionary lookup was 29.74%, which is significantly lower than 62.90% F1 score of a CRF model trained on lexical and morphological features. The most noticeable difference is in the Lab observations category. There is an almost 60% absolute difference between the dictionary matching and the machine learning approaches.

As shown in Table 3, system setting c, adding syntactic features slightly improves the overall performance by 0.3%. There are minor decreases in two categories (symptom and ECG findings), however the improvements in the Lab observations category outweigh the decreases. The ICD diagnosis categories remain largely unchanged. These

results are consistent with the nature of our annotations. Lab observations often contain phrases such as "troponin bumped to 26 from 0.21". Part of speech features can capture the shallow syntactic structure of these phrases, thus enabling the CRF model to learn from them. On the other hand, ICD diagnosis is more homogeneous, and usually follows a predictable pattern, for example, a number followed by "acute myocardial infarction". Little variation in the syntactic structures does not leave much additional information for the POS tagger to provide.

Contributions from semantic features can be seen in Table 3, system settings d to f. We induced Brown clusters from the the clinical text corpus, using a minimum word frequency of one, and two difference sizes (100 and 1000). Prefixes of length 4, 6, 10 and 20 were incorporated into the basic CRF model. These word representations outperformed the basic system, and achieved similar or better results compared to the systems trained on the syntactic features. Both cluster sizes consistently outperformed our basic CRF model across all entity categories. Using a large number of clusters resulted in a 3.10 percentage gain in overall F1 measure. However, the trend was reversed when word embeddings representation was incorporated into the basic CRF model. This representation was learned from Wikipedia text. Our system performance suffered from a decrease in the symptoms category, which accounts for 45% of the total entities in our dataset. This resulted in a lower overall performance. One reason the word embeddings proved not beneficial is that only 38.7% of the entity tokens in our corpus appear in the word embeddings. Moreover, some medical abbreviations could have different meanings in general text. For example, "abd" is an abbreviation for abdomen or abdominal. However, in Wikipedia, the disambiguation page for this abbreviation links to over 10 pages, none of which is abdomen. Therefore, the low-dimensional vector learned for this word would not be able to capture its meaning in a medical context.

Table 3. System performance

System Setting		**Symptom**	**ECG Findings**	**Lab Observations**	**ICD Diagnosis**	**All**
a. Dictionary Lookup Baseline	Precision	22.71	46.13	19.38	100.00	28.65
	Recall	30.25	44.11	16.62	47.46	30.91
	F1	25.94	45.10	17.89	64.37	29.74
b. Basic CRF model	Precision	53.73	78.31	86.41	87.98	69.77
	Recall	42.80	72.10	73.17	81.67	58.30
	F1	47.00	74.20	77.70	83.90	62.90
c. Basic CRF + POS	Precision	53.48	77.75	87.54	87.98	70.11
	Recall	41.63	71.48	76.32	81.67	58.59
	F1	46.10	73.80	80.20	83.90	63.20
d. Basic CRF + 100 Brown clusters	Precision	55.12	77.65	85.55	89.31	69.81
	Recall	44.35	71.99	71.36	81.67	58.57
	F1	48.60	73.90	76.80	84.50	63.10
e. Basic CRF + 1000 Brown clusters	Precision	59.29	79.17	90.14	89.60	73.16
	Recall	49.22	73.57	72.19	84.92	61.58
	F1	53.00	75.44	79.00	86.44	66.00
f. Basic CRF + Wikipedia Word Embeddings	Precision	48.21	75.00	90.00	100.00	65.18
	Recall	40.91	70.59	72.00	100.00	56.59
	F1	44.00	72.00	80.00	100.00	60.00

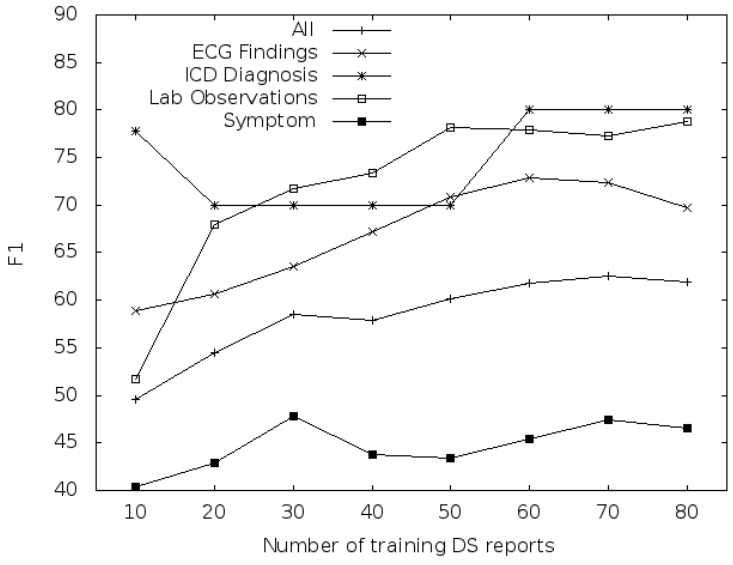
We have shown that semantic features obtained from general English corpora such as Wikipedia provides little benefit, if any, to our system. To further investigate the effects of using general domain word representation, we incorporated Brown clusters induced from newswire text. The performance from these clusters shows no improvement or a decrease over our basic CRF model. The results are listed in Table 4.

Table 4. System performance using Brown clusters induced from newswire text.

System Setting		**Symptom**	**ECG Findings**	**Lab Observations**	**ICD Diagnosis**	**All**
Basic CRF + 100 Brown clusters (newswire text)	Precision	52.47	79.02	85.18	89.31	69.14
	Recall	43.12	72.35	74.51	81.67	58.74
	F1	46.70	74.80	77.80	84.50	62.90
Basic CRF + 1000 Brown clusters (newswire text)	Precision	52.58	78.43	85.25	88.81	69.04
	Recall	41.97	71.23	72.77	80.00	57.66
	F1	46.10	73.80	77.00	83.30	62.10

Figure 2 shows the system F-1 scores using the best performing setting (basic CRF with 1000 Brown clusters induced from clinical text) with different sizes of training data. 20% of data is reserved for testing. Due to the small amount of ICD Diagnosis annotations, the performance varies more than the other categories.

Figure 2. F1 score of best performing setting with varying size of training data.



Discussions

Despite the lower inter annotator agreement (IAA) on the initial 25 DS reports, ICD diagnosis is consistently the highest performing category among all the entities we annotated. This could be explained by the fact that these entities exhibit a particular pattern, a number followed by one of a set of AMI related phrases, in capital letters. Lexical and morphological feature in our basic CRF model already captures such patterns. The low IAA is due to the linguist annotator annotating other occurrences of these AMI phrases as ICD diagnosis, or including more words.

The lab observations category sees the highest improvement with the addition of the part of speech features. Both precision and recall increased over the basic CRF model, suggesting the model benefited from the syntactic structures. Semantic features improved the precision score, at the same time decreased the recall score.

Errors of the other two types of entities (symptom and ECG findings) mainly stemmed from false negatives and false positives. There are in total 157 cases of false positives and 318 cases of false negatives. One reason for the false positives is that the model learned from the modifiers of the annotations but labeled the modifiers only, as in "not radiate to jaw or left arm". The most frequent false negatives errors are due to conjunctions or lists of symptoms, such as "chest pain, SOB, Diziness, Syncope, Palpitation or dizziness". Another reason is sentence-like entities. For example, "did not have a markedly elevated cardiac enzymes", and "trended his troponins and they peaked at 35". Miscategorization only accounts for a small percentage of the errors. In our basic CRF model, only 17 tokens, or 7 entities, were classified into a wrong category. One example is where the ECG findings entity "No ST elevations or depressions" was recognized as a symptom entity.

Another source of errors is in-exact boundary detections. There are 161 entities that match one boundary of the human annotations. Many of these boundary mismatches are due to the modifiers. For instance, our system recognized "acute onset of chest pressure" as a symptom entity whereas the gold standard only contains "chest pressure". This is consistent with the large discrepancy between the strict and non-strict inter-annotator agreements on the symptoms category.

Conclusion and Future Work

Worcester Heart Attack Study has been used to study comparative change in attack and survival rates of Acute Myocardial Infarction. However, the EHR of patients hospitalized with possible AMI in the WHAS dataset are manually reviewed and validated. This process is time-consuming and cumbersome. An automatic system that can extract key information from the EHR can speed up this manual process.

In this study, we evaluated CRF models on clinical entity recognition, specifically AMI related concepts that are used to validate patient's AMI status. We investigated the contributions of syntactic and semantic features. We demonstrated in our experiments that both types of features could improve the overall system performance. The F1 measure achieved a 3% to 3.10% increase when the features are trained from EHR, whereas features induced from general English text (newswire and Wikipedia) were not beneficial. The models are available upon contacting the authors due to IRB concerns.

There are many avenues to explore in future work. We will conduct a more thorough evaluation of annotation consistency. We will investigate contributions of word embeddings induced from clinical text, and compare with those induced from general English text. As discussed in the previous section, annotations with modifiers pose a challenge to learn an effective model. We will study how syntactic structures deeper than parts of speech can improve system performance. We will also explore the performance of these models in the context of the overall validation process.

A Comparison of Data Driven-based Measures of Adherence to Oral Hypoglycemic Agents in Medicaid Patients

[1]Vivienne J. Zhu, MD, MS, [1]Wanzhu Tu, PhD,
[1]Marc B. Rosenman, MD, [2]J. Marc Overhage, MD, PhD,
[1]Regenstrief Institute, IN and [2]Siemens Healthcare, Malvern, PA

Abstract: *We evaluated and compared different methods for measuring adherence to Oral Antihyperglycemic Agents (OHA), based on the correlation between these measures and glycated hemoglobin A1C (HbA1c) levels in Medicaid patients with Type 2 diabetes. An observational sample of 831 Medicaid patients with Type 2 diabetes who had HbA1c test results recorded between January 1, 2001 and December 31, 2005 was identified in the Indiana Network of Patient Care (INPC). OHA adherence was measured by medication possession ratio (MPR), proportion of days covered (PDC), and the number of gaps (GAP) for 3, 6, and 12-month intervals prior to the HbA1c test date. All three OHA adherence measurements showed consistent and significant correlation with HbA1c level. The 6-month PDC showed the strongest association with HbA1c levels in both unadjusted (-1.07, P<0.0001) and adjusted (-1.12, P<0.0001) models.*

Background

Medication non-adherence is a major problem in health care, especially among patients with chronic conditions like diabetes, which has estimated non-adherence rates between 36% and 87%.[1] Non-adherence to prescribed oral antihyperglycemic agents (OHA) can cause serious consequences to diabetic patients, with higher rates of micro- and macro-vascular complications, increased emergency medical events and a higher mortality rate.[2] In addition, the costs of poor medication adherence for all conditions are estimated at hundreds of billions of US dollars per year.[3] Despite the known consequences, one study reported that the medication adherence rate for patients with diabetes has not improved for over 30 years.[4]

Although an effective adherence intervention may have a greater effect on population health than many other medical treatment improvements,[5] information about patients' adherence is usually not available to health care professionals. Patient self-reported medication adherence is sometimes used to estimate patient medication taking behavior, but they are subject to recall bias and do not correlate well with other methods of assessing adherence.[6-7] While successful interventions have combined convenient care, information, reminders, self-monitoring, and counseling,[8] studies also suggest that developing a data-driven approach to better measure adherence and initiating interventions in clinical practice can potentially improve both adherence and clinical outcomes.[9] An accurate assessment of OHA adherence and understanding its association with glycated hemoglobin A1C (HbA1c level), which is one of the objective measures of glycemic control for diabetic patients, is the first step towards improving OHA adherence.

The definition of adherence varies, and there is no consensus on the best method of measurement. The medication possession ratio (MPR) reflects the patient's overall accordance with the prescribed dosing regimen and disregards the timeliness of particular refills. On the other hand, both the proportion of days covered (PDC) and the gap (GAP) focus on duration or continuation of prescribed treatment, and they both take the timeliness of each refill into account.[10] In addition, different time frames are used to measure adherence; the most frequently used is 12-months.[11] However, some studies showed significant improvement in health outcomes if patients have good medication adherence in 3-month or 6-month intervals. In order to identify the most helpful feedback to physicians, the adherence measures that are best correlated with the HbA1c level, PDC, MPR, and GAP across different intervals should be analyzed and compared.

Previous studies have demonstrated the significant association between OHA adherence and HbA1c level in clinical trials or specific diabetes management programs.[12-14] However, the subjects of these studies were followed for short periods of time or they were informed that their medication use was being monitored. The extent to which these design features affect the validity of study findings remains unclear. As a result,

conclusions drawn from these studies provide somewhat limited insight into the long-term effectiveness of drugs in real-world populations and settings.

In order to identify the measure of patient adherence best suited for providing feedback to physicians, we undertook a study using data from a population-based health information exchange (HIE). We calculated OHA adherence using three different measures (PDC, MPR, and GAP) across three time intervals (3, 6, and 12 months) utilizing longitudinal HIE data. We also analyzed and compared the effects of these objective adherence measurements and patient factors on HbA1c level based on laboratory test results from our local, operational HIE.

Methods

Data sources and settings

We extracted patient information from Indiana Medicaid data which contained demographic (race, gender and age), diagnosis, and treatment information over time. The OHA prescription claims records include refill dates, days of supply, dose, and frequency. HbA1c test results were retrieved from the Indiana Network of Patient Care (INPC). The INPC is an operational regional clinical informatics network that has served Indianapolis for more than fifteen years (and now includes more than 90 Indiana hospitals and more than 22,000 physicians among its members). This system delivers medical record information from hospitals, laboratories, imaging centers, pharmacies, and physician offices, including registration records, laboratory tests, radiology reports, diagnosis and administrative data.[15] The claims-based medication dispensing data was linked to the INPC laboratory data by medical record number. The medical record number is assigned to patients once they visit any facility in the INPC institutions, such as hospitals, laboratories, and clinics. This study was approved by the Institutional Review Board of Indiana University and the INPC Management Committee.

Eligibility Criteria

The study sample was limited to patients with Medicaid coverage who were prescribed an OHA and who had HbA1c data in the INPC. Inclusion criteria were established as follows for the study period January 1, 2001 through December 31, 2005:

1: 18-64 years old in Indiana Medicaid data during the study period.
2: Have at least one *International Classification of Diseases, Ninth Revision, Clinical Modification* (ICD_9_CM) code for Type 2 diabetes (250.X0 or 250.X2) in Medicaid claims for either inpatient or outpatient encounters.
3: Have at least one First Databank *Standard Therapeutic Code* (STC: 71) for OHAs: Biguanides, Sulfonylurea (SU), Thiazolidinedione (TZD) and other OHAs (Meglitinides and α-glucosidase) in Medicaid medication claims.
4: Does not take fixed-combination OHA regimens.
5: Does not take insulin (STC: 0177).
6: Have a medical record number in the INPC from one of the major hospital systems in Central Indiana.
7: Have at least one HbA1c test result from the INPC during the study period.
8: Have at least one OHA prescription prior to HbA1c test date.

Measurements

The independent variable, medication adherence, was measured by calculating PDC, MPR, and GAP. PDC is defined as the total number of medication-covered days divided by the number of days in a certain time period. PDC can be calculated if a subject has even one fill and has been used increasingly to measure patient medication adherence for quality assurance.[16] MPR is commonly calculated as the total number of days supplied by all refills divided by the number of days between the first and last refill, and it usually requires at least two refills date to be caculated.[17] Both PDC and MPR range from 0 to 1. GAP assesses any lapse in medication therapy. GAP is measured in days with various lengths where 30 days is considered significant enough to cause suboptimal clinical outcomes. [16] Both MPR and GAP need at least two refill dates to be calculated.

The dependent variable was the patient HbA1c level based on the INPC laboratory test results. To dynamically and accurately reflect the effect of OHA adherence on HbA1c level, we defined the HbA1c

test date as the index date, and then traced back the patient medication adherence prior to this index date. For each patient, MPR, PDC, and GAP were calculated for 3-month, 6-month, and 12-month intervals prior to each HbA1c test date. For patients who were taking multiple OHAs, the average adherence was counted to reflect the overall medication taking behavior.

In order to control for possible confounders which may influence patient HbA1c levels, [18-19] we analyzed age, gender, race, duration of OHA treatment, and number of concurrent OHAs. The prescribed OHA drug classes included Biguanides, Sulfonylurea, Thiazolidinedione, other OHAs, and multiple classes.

Statistical Analysis

Levels of patients' medication adherence were assessed through three different metrics: PDC, MPR, and GAP, measured over 3, 6, and 12-month intervals. Average HbA1c values were calculated and reported. We examined the associations between HbA1c level and various adherence metrics using mixed effect generalized linear regression models. Random subject effects were used in these models to accommodate the potential association among observations contributed by the same study subjects. All analyses were implemented using SAS 9.1 (*SAS Institute, Cary, North Carolina*). *p*-values less than 0.05 were considered significant.

Table 1. Summary of selected characteristics of subjects and their hemoglobin A1c

	Number of Subjects (Percentage) (n=831)	HbA1c (%) Mean (95% CI)

Other	44 (5.29%)	6.81 (6.08-7.53)

Results

Demographic and Clinical Characteristics

A total of 831 subjects met all inclusion and exclusion criteria. The average entry age of study subjects was 48 years. Female subjects accounted for 68.7% of the sample. The average HbA1c level of the study

population was 7.60% (95% CI: 7.58%-7.71%). The average duration of OHA treatment was 2.09 years. The average number of HbA1c tests was 3.5 per patient. The majority of the study sample (61.0%) was taking one medication: 27.0% were prescribed Biguanides, 25.8 % SUs, 3.0% TZDs and 5.3% other drugs. More than one OHA was being taken by 39.0% of patients; such patients had a slightly lower HbA1c level than patients who were treated by SU only (Table 1).

OHA Adherence, Other Covariates, and Their Association with HbA1c Control
From January 1, 2001 to December 31, 2005, a total of 1,721 to 2,934 observations of OHA adherence and HbA1c results were formed for 831 subjects. Table 2 summarizes frequency and average value of adherence (PDC, MPR and GAP) at time intervals of 3, 6, and 12-months. The average adherence ranged from 39% to 85%. In unadjusted analyses, all three OHA adherence measurements for 6 or 12 months showed consistent and significant associations with HbA1c control. In adjusted analyses, PDC and MPR measured for 6 or 12 months were significantly correlated with HbA1c. The 6-month PDC showed the greatest association with HbA1c control in both unadjusted and adjusted analyses (Table 3).

Table 2. Patient adherence measures mean value and the 95% confidence interval across three time intervals

	3-month		6-month		12-month	
Adherence	**Mean (95 CI)**	**Freq**	**Mean (95 CI)**	**Freq**	**Mean (95 CI)**	**Freq**
PDC	0.60 (0.59-0.61)	2,795	0.51 (0.49-0.52)	2,838	0.39 (0.38-0.41)	2,934
MPR	0.85 (0.84-0.86)	1,721	0.82 (0.81-0.83)	2,117	0.79 (0.78-0.80)	2,336

-- data did not converge
† *p*-value is greater than 0.05. *p*-value for any other unadjusted coefficients is smaller than 0.0001.

Adjusted with other factors, the coefficients between the 6-month adherence (PDC, MPR and GAP) and HbA1c level are shown in Table 4. The 6-month PDC showed greatest association (-1.12, P<0.0001) with HbA1c control. Among patient factors, increased age was correlated with better HbA1c control (P<0.0001). African-Americans had a higher average HbA1c level as compared with Whites (P<0.0001). The associations between number of medications and HbA1c level were about 0.41 (p<0.0001). Compared with patients treated with multiple OHA classes, patients treated with SU had slightly higher HbA1c levels (P<0.0001). Gender and duration of OHA treatment had no effect on HbA1c level.

Discussion
We have two main findings from this study. First, increased PDC and MPR are strongly correlated with lower HbA1c level while increased GAP relates to higher HbA1c level. Second, across different adherence measures and different time frames, 6-month PDC is more correlated with HbA1c level than other measures in both unadjusted and adjusted models.

The primary goal for this study is to analyze and compare associations between measurements of OHA adherence and HbA1c level among patients with Type 2 diabetes using real-world clinical data. In most cases (except in the 3-month models), PDC and MPR produced significant negative coefficients with HbA1c level, meaning that increased PDC or MPR is related to decreased HbA1c level. On the other hand, GAP produced positive coefficients, which means that increased GAP is associated with increased HbA1c level. The coefficients in the unadjusted model indicated that a 10% increase in PDC/MPR is related to a 0.09-0.10% reduction in HbA1c. In contrast, an increase in GAP of one is correlated with a 0.19-0.25% increase in HbA1c level. The adjusted model demonstrated similar results except that GAP is not significantly correlated with HbA1c These findings are consistent with results from previous studies that OHA adherence was independently associated with HbA1c control: HbA1c decreases 0.10% to 0.16% for each 10% increment in OHA adherence.[20]

All three measures of adherence, PDC, MPR, and GAP, were significantly correlated with HbA1c control but in different degrees. PDC had the biggest coefficient values in both adjusted and unadjusted models which indicated that PDC was most correlated with HbA1c level (Table 3, Table 4). These results are consistent with how PDC, MPR and GAP are calculated. MPR is calculated by adding the days' supply for all medications and then dividing over a certain period of time. [17] It assumes that all drugs eventually get used within the time period, which may overestimate the actual adherence if patients refill their medication before the last date of the preceding prescription. In contrast to MPR, PDC looks at each day to determine if the patient has one or more dispensed drugs and then determines the proportion of days that a patient has a drug available in a study interval. [16] Theoretically, PDC more accurately reflects patient adherence behavior, and it more effectively handles drug switching and prescription overlaps. GAP is simply measured by calculating the number of medication lapses greater than 30 days,[16] and it can be used as a reference to confirm the pattern of PDC or MPR (Figure 1).

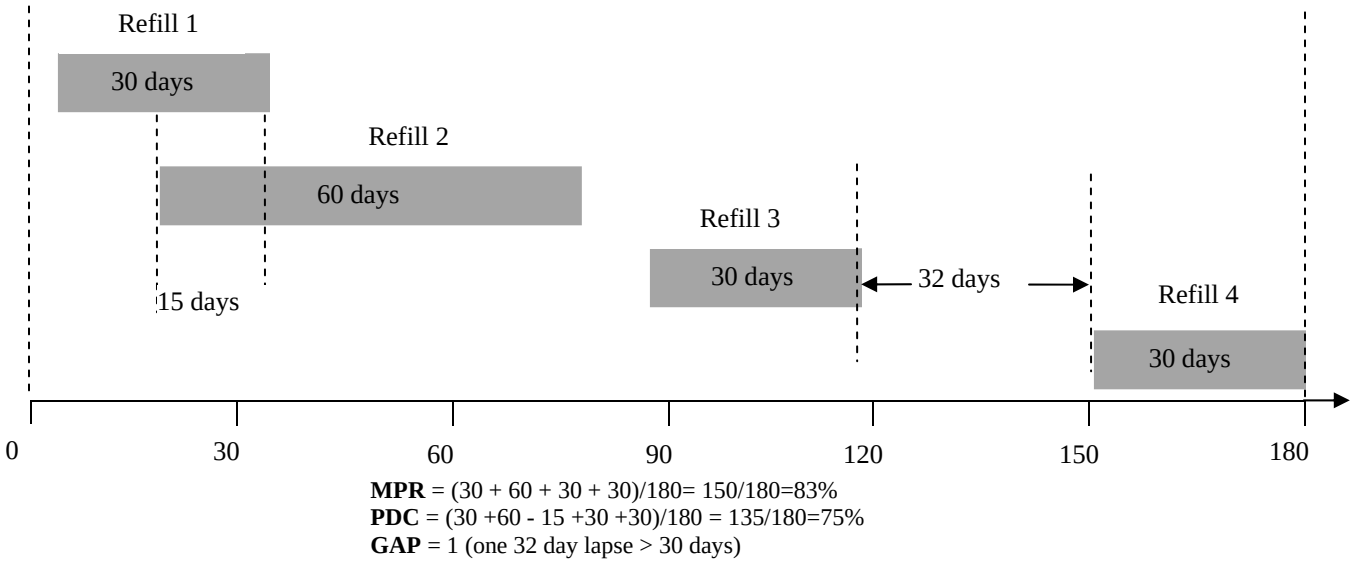

Figure 1. An example of calculating MPR, PDC and GAP.

This study also compared OHA adherence with HbA1c control across three time intervals. In the unadjusted model, significance disappeared for both MPR and GAP in the 3-month interval. Further investigation showed that 11% of refills were prescribed with a 90-day supply, resulting in insufficient information to calculate the MPR and GAP since they both would need at least two refill dates during the 3-month interval. The coefficients were close for PDC, MPR, and GAP across the 6-month and 12-month intervals. However, from a clinical perspective, the 6-month interval can provide patient adherence information in a more timely fashion. In summary, the 6-month PDC most accurately reflects OHA adherence and is the measure most closely associated with HbA1c level for patients with Type 2 diabetes in our study.

It is well-known that race is one predictor of suboptimal HbA1c control.[20] In our study, compared with Whites, African-Americans had a significantly higher HbA1c level (by 0.28-0.30%, $p<0.0001$). Sociodemographic, behavioral, genetic, or biological factors may independently or partially affect HbA1c level.[21-23] Our study also found that increased age is related to better HbA1c control, which is generally consistent with the notion that young patients are less likely to benefit from OHA therapy.[22] We additionally observed positive associations between number of concurrent OHAs and HbA1c levels. Patients were prescribed one additional OHA when their HbA1c level increased by 0.4%. A plausible explanation might be that patient may have been prescribed additional OHAs because they were not responding to one. [25]

The main findings from this study provided evidence and knowledge to establish intervention in medication adherence to improve health outcomes for patients with Type 2 diabetes. Challenges of medication adherence in diabetes are at patient, medication and provider levels, and a multi-dimensional approach is required to establish efficient interventions. Health information technology (HIT) and health information exchange (HIE) offer great potential to establish such a system. First, objective and data-driven approaches can be programmatically established through an HIE. These objective adherence measures enable accurate assessment of patient medication taking behaviors, which is the essential for physicians to estimate the effectiveness of treatment. This study provides specific information on which to base a choice for adherence measures in clinical practice. Second, a clinical decision support system may deliver patient adherence information and generate relevant recommendations in routine clinical practice. In addition, a well-established HIE/HIT supports patient-centric and team-based care that better engaged patients, providers and health care systems for improving medication adherence.

Limitations

Certain limitations should be recognized. First, the study population was Indiana Medicaid members

younger than 65, with relatively low socioeconomic status and with at least one HbA1c laboratory result in the INPC which covers the central Indiana region most closely. Therefore, the findings from this study may lack generalizability to all patients with Type 2 diabetes, including those who had no HbA1c results recorded in the INPC. Second, dispensing claim-based measures may not be equivalent to measures of the actual ingestion of medication. Nevertheless, filling a prescription is usually consistent with taking medication.[26] It also should be noted that it is possible we did not capture dispensing information about free samples or free medications offered by providers or pharmacies. Third, the average HbA1c levels of this study population were elevated (>7.0%) even though the average OHA treatment duration was 2.09 years. Provider inertia may be playing a role in inadequate glycemic control apart from patient adherence. However, we lack the necessary data to further analyze if providers have failed to adequately intensify OHAs, or to initiate insulin or HbA1c tests.[27] Similarly, the comparisons of different OHA adherence measures mainly rely on their effects on HbA1c levels, and we did not study pharmacodynamics/kinetics contributions, which may also affect patient HbA1c levels. Fourth, we excluded patients using insulin. However, insulin is commonly administered to patients with Type 2 diabetes whose HbA1c is poorly controlled. One study suggested that insulin use may affect adherence rates to oral medications.[28] Whether there is a significant association between insulin use and OHA adherence is an area for further study.

Conclusion

By evaluating real-world clinical data from the INPC and Medicaid claims data, this study confirmed the strong association between OHA adherence measured by PDC/MPR and HbA1c level among Medicaid patients with Type 2 diabetes. The 6-month PDC is the best measure of OHA adherence in this population. This study also suggested that linking HIE laboratory data with claims data is a helpful approach for comparing medication adherence and clinical phenomena.

Building a Treebank of hospital discharge summaries

Min Jiang, M.S.[1],
Yang Huang, Ph.D.[2], Jung-Wei Fan, Ph.D.[2], Elly W Yang M.A.[2], Hua Xu Ph.D.[1]
[1]School of Biomedical Informatics, The University of Texas Health Science Center at Houston, Houston, TX, USA
[2]Kaiser Permanente, San Diego, CA, USA

Introduction In order to build high-performance syntactic parsers in the medical domain, Treebanks that contain manually annotated parse trees of clinical sentences are needed. Current efforts on clinical Treebank include the MiPACQ corpus that consists of various types of clinical notes about colon cancer and a small collection of 25 progress notes that we built previously. In this abstract, we describe our current effort on building a Treebank of hospital discharge summaries, an important type of clinical documents that cover a broad type of clinical concepts.

Method In our previous study, we developed a parse tree annotation guideline[1] for clinical sentences that are often ill formed. Here we applied this guideline to annotating discharge summaries contained in the 2010 i2b2 clinical NLP challenge, a total of 237 documents. Every sentence in these discharge summaries was preprocessed by the Stanford parser and a researcher in clinical NLP manually reviewed each parse tree generated by the Stanford parser and corrected them based on the annotation guideline. We used WordFreak, an annotation tool, to perform our manual annotation. When there is any question about a parse tree, a linguist and a physician were consulted for correct annotation. To ensure the quality of annotation, a small subset of sentences in discharge a second NLP researcher also annotated summaries.

Results Thus far, we have annotated 60 discharge summaries, accounting for about 6000 sentences. Compared with progress notes, discharge summaries show some different characteristics. In average, the sentence in the progress notes contains 8.1 tokens, which is far less than the one in the discharge summaries (15.3 tokens). Furthermore, Table 1 shows a preliminary comparison of the distribution of main syntactic constructs (constituents) in two Treebanks. Compared to the progress notes Treebank, Noun Phrase has the biggest increase of the portion (increase from 40.0% to 46.8) in all the constituents of discharge summaries Treebank and Verb Phrase drops the most on the percentage of all the constituents in discharge summaries Treebank.

Discussion Due to the inherent differences in the use of progress notes and discharge summaries, there is a difference in the sentence structure found in these two types of notes. Progress notes are usually written in an informal, brief manner, which explains the difference in the sentence length from the discharge summaries. On the other hand, discharge summaries, as a summary of all the clinical reports, contain more comprehensive clinical concepts and probably more syntactic patterns. Therefore, a Treebank of the discharge summaries would be a valuable data set for building more generalizable parsers for clinical notes. We plan to finish annotating all discharge summaries in the i2b2 data set and make the Treebank freely available to the research community.

Table 1 – Statistics of distribution of main syntactic constituents in two Treebanks

Constituent label	**S**	**Frag**	**NP**	**VP**	**PP**	**ADJP**	**ADVP**	**SBAR**
Constituent description	Sentence	Fragment	Noun phrase	Verb Phrase	Prepositional Phrase	Adjective Phrase	Adverb Phrase	Clause
Progress notes	12.2	7.7	40.0	16.8	8.7	4.5	2.8	1.4
Discharge summaries	9.4	7.9	46.8	13.9	10.5	2.8	3.6	1.3

The Pareto Principle in the ICU: A Model for Knowledge Resource Health Information Technologies

Christopher A. Aakre, MD, Marc A. Ellsworth, MD, Brian Pickering, MD, Vitaly Herasevich, MD, PhD
Mayo Clinic, Rochester, MN

Abstract: *The frequency and distribution of medication orders and lab results in intensive care units follow the Pareto Principle, colloquially known as the "80/20 Rule". Utilizing this knowledge is helpful in the design of health information technologies, most specifically point-of-care knowledge resource tools, which limit information overload and provide clinical users with the most pertinent and needed clinical information.*

Introduction: Clinical providers in the intensive care unit are confronted daily with large amounts of data. This data must be distilled into clinically useful information in real-time for use at the bedside. When designing a health information technology solution to reduce information overload and user-interface clutter, it is important to understand the frequency and distribution of the clinical data available to providers at the point-of-care. We hypothesized that the frequency of medication orders and lab results in the neonatal intensive care (NICU), pediatric intensive care (PICU), and medical intensive care (MICU) units follow the Pareto Principle.[1] This concept has previously been validated in the outpatient setting,[2] but it has not yet been validated in a real-time data-intensive inpatient setting such as the intensive care unit.

Methods: The Multidisciplinary Epidemiology and Translational Research in Intensive Care (METRIC) DataMart, combines real-time ICU clinical information from many EMR systems at the Mayo Clinic into one searchable integrative database.[3] This DataMart was used to retrieve all medication orders and lab results that occurred in our institution's NICU, PICU, and MICU from January 1, 2012 – December 31, 2012. Our simple Pareto Plot was created by comparing the frequency of each specific medication and lab test against the cumulative number of medication orders and laboratory test results.

Results: During the study period the total number of medication orders and unique medications were as follows: NICU – 9,065/179; PICU – 25,054/478; MICU – 83,997/700. The total number of lab results and unique lab tests were: NICU – 65,044/459; PICU – 89,202/900; MICU - 367,905/1,033. Within their respective units, the top 20.1% (NICU), 15.2% (PICU) and 9.9% (MICU) of unique medications accounted for 80% of all medication orders. Similarly, 4.6% (NICU), 3.2% (PICU) and 3% (MICU) of all unique laboratory tests were responsible for 80% of all laboratory results.

Discussion: In contrast with the outpatient setting previously studied by Wright et al, the intensive care unit is an environment with a high volume of time sensitive data. The large volumes of complex data in this setting make point-of-care knowledge resource tools attractive to busy clinicians. Our data demonstrates that the frequency of medication orders and lab results in the intensive care unit follow the law of the vital few, otherwise known as the Pareto Principle. When designing point-of-care knowledge resource tools for the intensive care setting, the application of the Pareto Principle can help identify the most common clinical data for inclusion - thereby reducing interface clutter from less frequently used items. In most common data scenarios confronting the intensive care clinician, the Pareto Principle suggests that the most common 20% of clinical data will generate a vast majority of the alerts. A careful design of the point-of-care knowledge tool's interface may help minimize alert fatigue attributed to the most common data obtained in the intensive care unit. Further study is needed to characterize clinician attitudes on frequency of alerts pertaining to less familiar data.

Electronic Dental Record Research: descriptive review of current status

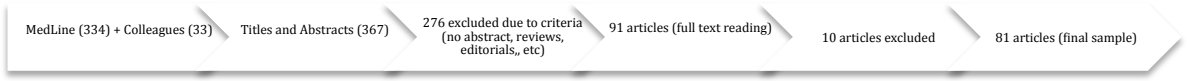
Renata Abramovicz-Finkelsztain MDS, PhD candidate [1],
Claudia G N Barsottini MSc, PhD, Associate Professor[1],
Heimar Fatima Marin MSc, PhD, Full Professor[1]
Department of Health Informatics, Universidade Federal de São Paulo, Brazil

Abstract

As the adoption of Electronic Dental Record (EDR) increased during the last decade, so did the research in the field. In order to describe the current status of the research related to EDR we developed a descriptive bibliometric review followed by a description of the methodology and object of the found studies.

Introduction and Methods

During the last decade surveys indicated a worldwide trend in the use of Electronic Dental Record (EDR) for the management of patient clinical data.(1-4); and, as a consequencet so does the research related to this field. In order to describe the current status of the electronic dental records research we did a bibliometric research(5). In addition, we also described the articles according to their methodology and object of the studies. A research strategy was developed and the data source used was Medline and known authors from the field contribution.



Results

The 81 articles included in the review were published among 41 different journals. The Journal of the American Dental Association, The Journal of Dental Education and the Journal of Public Health Dentistry held 13, 10 and 4 articles each respectively. From the 41 journals, 30 were indexed both in Journal Citation Reports (JCR) and Scientific Journal Ranking (SJR), with an index factor ranging from 0,771 to 7,735; 9 were indexed only in SJR , with index factor ranging from 0,119 to 3,758 and the remaining 2 were not indexed in neither of the databases. The articles selected for the review were analyzed based on the country of origin (Figure 1), the methodology used and the object of the study (Figure 2). A research trend during the last decade is also shown. (Figure 3).

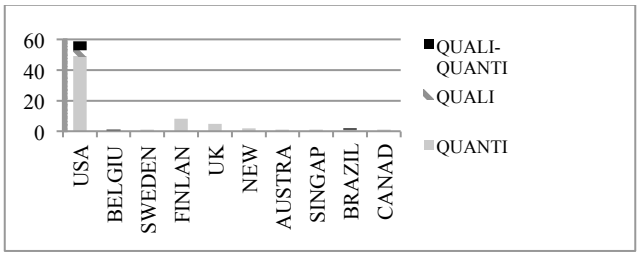


Figure 1- Country X Methodology

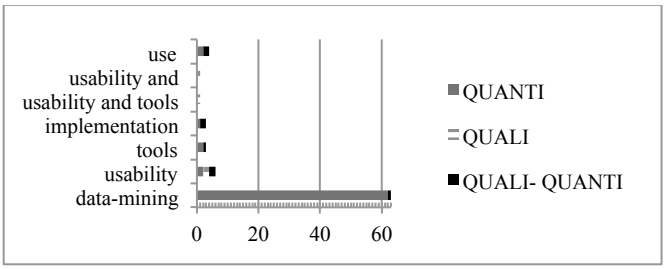

Figure 2- Methodology X Object of Study

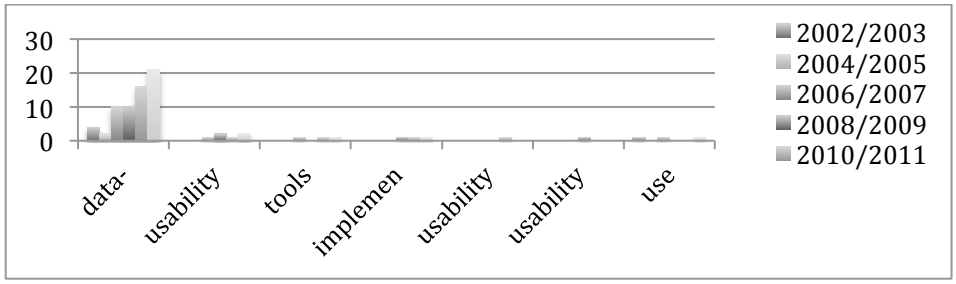

Figure 3- Research Trends

Discussion

While there has been a large number of published studies on EDR, the majority (78%) are editorials, reviews or description of use of the systems and only 22% represent research involving EDRs. From theses studies, only 20% (14 articles) studied EDRs themselves, i.e., evaluated use, usability, implementation and/ or tools. For this reason, it is our view that there is a lack of research on EDRs use and we need the urge the scientific community to develop more studies in order to increase and improve EDR's adoption.

Model selection for EHR laboratory variables: how physiology and the health care process can influence EHR laboratory data and their model representations

David Albers[1], PhD, Rimma Pivovarov[1], MA, Noémie Elhadad[1], PhD, George Hripcsak[1], MD MS
[1]Department of Biomedical Informatics, Columbia University, New York, NY

Abstract

Patient data are present in an electronic health record (EHR) for many reasons; the data in an EHR are a function of a complex set of processes ranging from physiology to the health care process (HCP). Understanding the impact of processes governing the data accumulated in the EHR on large-scale measurement analysis is an open research problem. Here we focus on modeling laboratory measurements independent of time. Phenotypes are collections of summary variables: a glucose measurement summarizes or maps the complex endocrine system to one number; a set of glucose values can then be condensed by parameterization from the set to a few parameters (e.g., a mean). Because EHR data can be influenced by physiology, the HCP, and context, selecting the most useful parameterization can be non-trivial. Moreover, the choice of parameterized model can have a significant impact on what we can observe and how well we can stratify a population into different phenotypes. Here we find that glucose in a broad EHR is best represented, summarized, and modeled by an generalized extreme value (GEV) distribution rather than by a mean and variance.

Introduction

The EHR can provide a platform for large-scale phenotyping. We believe that because EHR data are biased in the way they are recorded, data modeling must account for these biases. Our focus here concerns laboratory test data across a large patient population and developing a method for deconvolving biases and generating phenotypes. Here we show that the HCP intervenes in such a way that outside of an ICU, only extreme values of glucose are captured. As a consequence, large scale phenotype studies should use location and scale instead of mean and variance to model, summarize, and stratify populations.

Methods

Our analysis was conducted using data from the clinical data warehouse at our institution. We observed distributions of glucose in two contexts: an ICU population that is more likely to represent pure physiology, and a broad EHR population that is more likely to be influenced by the HCP. In addition, we modeled the individuals and the populations using normal and GEV distributions. These distributions are generated by distinctly different processes; importantly, GEV distributions are generated by measuring relative maxima of any distribution and are the only distributions that can model extrema of distributions. Moreover, glucose physiologic driven distributions show that mean- and variance-like quantities increase simultaneously with acuity [1]. We will use this to help understand how different statistical models could influence phenotyping though different model parameterizations.

Results

The ICU distribution of glucose is unimodal and symmetric, matching the distribution of glucose captured in a controlled setting where only physiology affects the measured values [1]. The broad EHR glucose distributions do not resemble the ICU glucose distributions but are well fit by a GEV distribution. The linear correlation (LC) between the mean and variance of glucose for the EHR population is 0.63 (95% CI 0.62-0.65). The LC between the location and scale, the mean and variance analogs for the GEV, are 0.82 (95% CI 0.82-0.83). The larger LC and smaller CIs imply the GEV is the natural parameterized family to model glucose in an EHR

Conclusion

The glucose distribution in the ICU represents a physiologic process. The glucose in the broad EHR is a function of both physiology and the HCP; the HCP intervenes such that only relative maxima of individual's glucose values are captured. The GEV is the only distribution that can represent extrema of distributions, implying that the EHR glucose data are collections of relative extreme values of glucose, or glucose captured when patients are ill. Because of this, we hypothesize that HCP biases the glucose in the EHR by only capturing individuals when they are acutely ill. This hypothesis is supported by the fact that location and scale have a strong positive LC that implies and signals increased acuity. With a weaker LC and wider CI, mean and variance do not distinguish healthy and sick individuals as well as location and scale. This means that for phenotyping studies, relative to glucose, it is better to use location and scale of glucose as summary variables for stratifying a population than mean and variance. It is likely that the most representative model will be lab and context dependent.

Health Information Technology Adoption in Home Health ... Research in Progress

Dari AlHuwail[1], Gunes Koru, PhD[1], Ahmad Alaiad[1], Anthony Norcio, PhD[1], Maxim Topaz[2]
1 Department of Information Systems - University of Maryland - Baltimore County, Baltimore, MD, ; 2 School of Nursing - University of Pennsylvania, Philadelphia, PA

Motivation

U.S. health care systems are constantly looking to provide higher quality of care, improve the health outcomes of patients, and reduce overall costs. Home Health Agencies (HHA) are key players in this ecosystem and are an important component of the patient-centered continuum of care. In 2012, Home Health expenditures were $77.8 billion and CMS spending alone accounted for approximately 81% of total home health care spending. [1] Health Information Technology (HIT) has "the potential for achieving numerous health care goals—including efficiency, cost-effectiveness, and patient-centered care". [2]

Research Aims

Today HHAs are ineligible to receive incentives under the Health Information Technology for Economic and Clinical Health (HITECH) act; many HHAs operate with very limited resources and expected to improve quality of care while lowering their costs. HIT adoption can potentially help HHAs to reap the benefits and become more effective. In this evidence-based investigation, we aim to uncover the challenges and opportunities for HHAs to e effectively adopt Health IT solutions. The research proposal was funded through the Agency for Healthcare Research and Quality (AHRQ).

Methods

We used qualitative methods in order to obtain rich and contextual information and inform the limited research in this domain. Purposeful sampling based on agency size, business model, organization structure, and geographical areas was implemented for agencies in the State of Maryland. Participants were recruited through the Maryland National Home Care Association and Maryland Health Care Commission. The unit of analysis was a single HHA. Semi-structured interviews were conducted with CEOs, CIOS, and clinical providers (including nurses and physical therapists). The interviews were recorded and transcribed. Member-checks were also conducted with participants to ensure findings' validity and reliability. The Framework method is used for analysis of the data. Such method is widely used by qualitative researchers allowing to organize raw data to uncover themes and concepts without loosing sight of original data through the different levels of abstraction.[2]

Research Status and Preliminary Findings

All interviews and member-checks were completed and transcribed. Certain themes are starting to emerge.

- For HHAs, compliance with regulatory requirements is complex, time consuming and costly process.
- Patients with varying demographics (including gender, age, and education,) introduce complex needs.\
- Coordination of care across the continuum of healthcare is critical for positive patient outcomes
- Physicians are resistant to use HHAs's HIT
- High turnover of HHA staffing and big age gap amongst clinical providers

Conclusion

HHAs struggle to keep up with complex regulations and requirements while operating with limited resources. Many operational and clinical challenges are complex to solve; effective and efficient HIT adoption is amongst such challenges. Evidence-based findings from this study will uncover issues of HIT adoption in HHAs to inform policy makers and HHA administrators.

Dental Information Needs – a Survey of the Medical Health Providers

Márcia C. Almeida, DMD, UCP[1], Amit Acharya, BDS, MS, PhD[2] , Altamiro C. Pereira, MD, PhD[3], André R. Correia, DMD, PhD, UCP[1]

[1]Portuguese Catholic University, Viseu, Portugal; [2]Marshfield Clinic Research Foundation, Marshfield, Wisconsin, USA; [3]CIDES, Porto, Portugal

Abstract

The aim of this study was to understand and analyze dental information needs of medical providers at the Portuguese National Health System and register their opinion of an integrated medical-dental electronic health record. The majority of the providers considered the implementation of such integrated system useful to support bi-directional flow of patients' health information between medical and dental providers.

Introduction

The feasibility of integrating medical and dental patient data should be considered in a holistic patient care approach due to the oral-systemic relations of several pathologies [1, 2]. The aim of this study was to analyze medical providers' core dental information needs and to get their opinion of an integrated medical-dental electronic health record in their workflow.

Methods

A twelve-question survey based on previously reported open/closed ended interviews [2] was distributed (face-to-face) to a sample of 346 physicians in Primary Health Care Centers and in St. Teotónio Hospital, in Viseu, Portugal. The survey focused on medical providers' dental information needs, referral to dentists and their opinion and considerations about the use of an integrated medical-dental electronic health record in their workflow.

Results

There was a 51% overall response rate. Eighty-nine percent of the respondents that included Otolaryngologists, general physicians and pediatricians considered bi-directional flow of patient data between dental and medical care providers essential to provide effective medical care. There was a significant difference in the attitudes of the physicians towards incorporating the different components of the dental data. About 49% of the respondents requested a dental appointment monthly or less, and 14% reported weekly. It was seen that 92% recognized the significance of implementing an integrated medical-dental electronic health record to facilitate access to dental data, specially the "oral health status" (Figure 1). About 58% of respondents requested dental clinical history and dental diagnosis to be displayed in the integrated dental and medical record. Furthermore, about 59% of respondent considered problem list to be significant. Pulmonologists, Internists and Physicians with fewer years of medical practice tended to devalue the sharing of this kind of information.

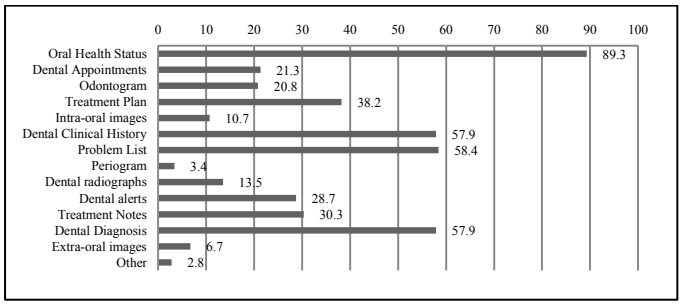

Figure 1. Medical provider's dental information needs

Conclusion

The results of this study indicate that implementation of a secure and confidential integrated medical-dental electronic health record may facilitate bi-directional access to relevant patients data, contributing to a more effective and efficient medical treatment. Capturing structured dental diagnosis in the dental practice is warranted since this was one of the top information that the medical providers find it important. A quantitative analysis of the advantages vs. disadvantages of an integrated medical-dental electronic health record environment can further be conducted to explore the feasibility of such an environment.

Abstract: *Computerized physician order entry (CPOE) systems can prevent medication errors but they can also introduce new types of errors. We aimed to test the vulnerabilities of a wide range of CPOE systems to medication errors, and to develop a more comprehensive understanding of how their design could be improved. We found a high degree of variability in alerting between different systems, which represents a safety concern. Safeguards need to be put in place to ensure safer prescribing.*

Introduction: CPOE systems with embedded clinical decision support (CDS) can play a major role improving patient safety. However, these systems are not failsafe and can also introduce new types of errors. The Institute of Medicine report *Health IT and Patient Safety: Building Safer Systems for Better Care* recommended that specific examples of potentially unsafe processes and risk-enhancing interfaces be identified and shared amongst the health IT community. This study aimed to test the vulnerabilities of a wide range of CPOE systems to medication errors, and to develop a more comprehensive understanding of how their design could be improved to advance patient safety.

Methods: As part of a National Patient Safety Foundation-funded project, we examined 13 unique leading vendor and homegrown CPOE systems in diverse organizations in United States and Canada. Typical users at each of 16 sites were asked to enter 13 different erroneous orders on test patients in the usual and customary way, and where necessary perform workarounds. A research pharmacist and research assistant independently observed test users enter each order, and rated the ease or difficulty of these entries using standardized operational definitions. An Excel file was created and detailed descriptions of users' observations and verbalizations were recorded. Overarching themes relevant to interface design and usability / workflow issues were identified, reviewed as a group, and any discrepancies resolved by discussion.

Results: We found these systems often failed to detect these errors. Firstly, the generation of electronic alert warnings varied widely between systems, and appeared to depend on how the order information was entered into the system (i.e., in a structured or unstructured way); whether a specific alert functionality (e.g., duplicate-drug checking) was operational in the system; and which drugs or drug combinations were included in the CDS algorithms. Secondly, the wording of alert warnings was found to be confusing, with unrelated warnings appearing on the same screen as those more relevant to the current erroneous entry. Thirdly, the timing of alert warnings differed across CPOE systems, with many dangerous drug-drug interaction warnings displayed only *after* the order was placed (e.g. both Imdur® (isosorbide mononitrate) and Revatio® (sildenafil) had been entered and the order signed off in two systems). Fourthly, alert warnings varied in their level of severity in different systems and even within the same institution (outpatient vs. inpatient system). Finally, users developed workarounds to avoid getting duplicate drug alert warnings, such as entering the brand name of the drug for the morning dose and the generic name for the evening dose.

Conclusion: We found a high degree of variability in ordering and alerting between different CPOE systems, which creates major vulnerability. Detailed qualitative analysis of both the observed CPOE functionality and users think-aloud comments provided rich insights into the ways both systems and users were susceptible to ordering errors. System developers and users need to assess these findings and build in safeguards to ensure safer prescribing for patients.

Public Perceptions of Privacy and Healthcare Quality Effects of Electronic Health Records

Jessica S Ancker, MPH, PhD,[1] Samantha Brenner, MD, MS,[2]
Michael Silver, MS,[1] Joshua Richardson, MLIS, PhD[1]

1. Weill Cornell Medical College, Department of Healthcare Policy and Research, New York, NY
2. Stanford Hospitals, Department of Internal Medicine, Stanford, CA

Abstract: *Our objective was to track consumer perceptions of quality effects and privacy risks associated with health information technology during the initial years of the federal electronic health record (EHR) incentive ("meaningful use") program. National random-digit-dial telephone surveys were conducted annually for three consecutive years, 2011 through 2013. During these years, consumers became more likely to report having a physician who used an EHR. Over time, fewer people expressed concern about privacy risks of electronic information, but simultaneously, slightly fewer endorsed the statement that EHRs would improve care. In all years, consumers whose doctors used EHRs were more confident that EHRs would benefit them. Public opinion about EHRs may be evolving over the three-year period coinciding with the beginning of "meaningful use."*

Introduction: Surveys have suggested that much of the American public agrees with federal policymakers that electronic health records (EHRs) will improve the quality of healthcare. Nevertheless, public concerns about risks to the privacy and security of electronic medical information remain common. Our objective was to track consumer perceptions of quality effects and privacy risks associated with health information technology during the initial years of the federal EHR incentive ("meaningful use") program.

Methods: National random-digit-dial telephone surveys were conducted annually for three consecutive years, 2011 through 2013. Both landlines and cell phones were sampled, and the sample size of 1000 provided a 3.1% margin of error each year.

Results: Response rates for each year of the survey ranged from 63% to 64%. In 2011 and 2012, 64% of respondents reported seeing at least one doctor with an EHR, and this percentage rose to 70% in 2013 ($p = .003$). In the first two years of the survey, 66% of respondents endorsed the belief that EHRs would improve the quality of healthcare they received, but this percentage dropped to 61% in 2013 ($p = .02$). Also in the first two years of the survey, the percentage who believed that EHRs would worsen the privacy and security of medical information remained approximately stable (47% and 50%), but dropped to 41% in 2013 ($p < .001$). In each of the three years, consumers who had experience with doctors using EHRs were more likely to believe EHRs would improve healthcare quality than those whose doctors did not use EHRs (e.g., 64% vs. 53% in 2013; odds ratio = 1.5; $p = .04$). In 2013, consumers whose doctors used EHRs were less likely to believe that EHRs threatened privacy and security (38% vs. 55% in 2013; odds ratio = 0.5; $p = .001$). This association did not appear in previous years.

Discussion: During the early years of the meaningful use program, consumers became more likely to report having a physician who used an EHR. Consumers with this exposure to EHRs were more confident that EHRs would benefit them. Both confidence in the quality effects of EHRs and concerns about privacy risks became somewhat moderated over time. Although causal relationships cannot be determined definitively from repeated cross-sectional surveys, it is possible that increased familiarity with EHRs over time is associated with evolution in public opinion about health information technology.

Emergency Department Information System Selection: A Structured Approach

Christine K Anderson, RN, BSN; Graduate Student, Clinical Informatics and Patient-Centered Technology;
University of Washington, Seattle, Washington

Project Aims: 1. Identify key elements in an effective emergency department information system (EDIS). 2. Use a participatory approach, including emergency department (ED) physicians and staff, to rank and assign weights to the key elements of an EDIS. 3. Use the information to develop a vendor assessment tool for the evaluation and selection of an EDIS for a critical access hospital in rural Alaska.

Background: Federal healthcare legislation requires meaningful use of a certified electronic health record (EHR) for a healthcare organization to receive maximum reimbursement for their services.[1] Urban and rural hospitals alike are expected to meet these standards by 2015 or face payment penalties. Multiple professional organizations recognize the EHR as a support to safer and more efficient patient care. Lack of efficient and usable EHRs is identified as a primary reason for delayed adoption.[2] Software designers and developers must consider inclusion of fundamental principles of design identified by professional health information organizations in their EHR product development. Including staff in the EDIS selection process helps build support of the product and its effective use.[3] Use of these fundamental design principles along with the inclusion of clinical staff in system selection of an EDIS will support successful selection and implementation.

Methods: A survey-based field study was conducted to develop a rubric for EDIS selection. The survey was developed following review of the literature identifying essential features of an effective EDIS and finalized with input obtained from experienced EDIS users via semi-structured interviews. The survey was available via *Catalyst*, an electronic survey application, and a paper format, to increase the survey response rate.

Results: With a survey response rate of 51% (20 of 39 eligible respondents) the essential features of an effective EDIS were identified and evaluated by clinical staff scoring each item as most important to least desired. Top 10 feature ratings came out of staff survey responses, (a) being most important and carrying a weighted score value of 10, and so on.

Criteria	Criteria Score	Weighted Score	TWCS*
a) Rapid access to past medical history using an interface between EHR systems, if needed		10	
b) Multi-user platform allowing more than one simultaneous user per chart		9	
c) Supports bedside data entry & use of mobile devices for EHR access		8	
d) Intuitive system design requiring minimal initial user training		8	
e) Electronic WhiteBoard for tracking patient status and diagnostic results		6	
f) Patient education materials linkage for diagnoses, medications and discharge planning		5	
g) Flexible EDIS platform for facility specific set up and use		4	
h) Embedded CDS processes to support evidence-based and patient safety initiatives		3	
i) CPOE functionality specific to ED processes		2	
j) Coding & billing linkage to documentation supporting efficient & optimal reimbursement		1	

* Total Weighted Criteria Score (TWCS = Criteria Score X Weighted Score)

Vendor	a	b	c	d	e	f	g	h	i	j	Vendor Total Score
1											
2											
3											

Conclusions: Implementation of an EDIS is in the future for all facilities that have yet to move into the digital age. Selecting an EDIS is a serious process for careful consideration. Patient safety and staff efficiencies are called into play when making this significant process change. Allowing staff to be part of the product selection helps engage them for successful implementation. A needs assessment and vendor assessment tool supports the objective and thoughtful process of vendor selection. The vendor assessment tool developed from the results of the staff survey can be utilized to for this purpose.

Pediatric Dose Range Checking with Hierarchical Rules to Provide Value Added Alerts

Charles H Andrus, MHA [1], Kevin O'Bryan MD [1], Patrick Feldman RPh [1], S. Paul Hmiel MD, PhD [2], Phillip Asaro MD [2], Feliciano Yu, MD, MSPH [2,1]

[1] St. Louis Children's Hospital, St. Louis MO; [2] Washington University School of Medicine, St. Louis MO

Abstract

Medication dosing rules for infants and children depend on many parameters, including patient weight, age (chronologic, and for infants, gestational), and indication, with per dose and daily limits. We describe a robust dose range checking system that allows for complex, hierarchical rules, while allowing near real time monitoring of alerts. Implementation was associated with decreased alert override rates, an increased acceptance of dosing recommendations, and an additional prescribing check on high risk medications.

Introduction

Clinical decision support (CDS) engines provide a mechanism to utilize the data elements of the EMR to provide relevant guidance to clinicians providing complex care. These complexities are exemplified by medication dosing rules for infants and children[1], as the clinician needs to consider age (chronologic age and for infants, gestational age), weight, indication, and per-dose and daily maximal dose limits, for many high risk drugs. We describe a robust dose range checking system that allows for complex rules, [1]systems (EMRs), while simultaneously limiting nuisance alerts.

Methods

All drug orders were tagged with a unique RxNorm code within the EMR. Dosing rules were developed from existing pediatric clinical pharmacology resources, by clinical pharmacists in collaboration with physician experts. Analysis of these rules revealed that any dose check could be represented as a combination of two types of rules: criterion rules and dose range rules. The rules were translated into criterion rules contained a criterion type such as flat dose, total daily dose, weight -based dose, or modifications based on gestational age or renal function. Criterion rules were developed with parent and child rules allowing complex dose-rule hierarchies including multiple input modalities. When a dose range check rule was applied to an order, it could result in any of 3 alert types: warning (user can proceed without a comment), soft stop (user must comment to proceed), hard stop (user cannot proceed).

Clinical Decision Support (CDS) logic for the dose range checking system is represented in Arden Syntax, and is separated from clinical content, which is held in tables within the EMR database. Thus alert messages and rules can be built and customized without MLM code changes by using a custom configuration tool. A new criterion rule type would require only one new Arden Syntax Medical Logic Module (MLM) to provide the logic of that specific criterion type. This approach provides extensibility and ease of maintenance. The .NET configuration tool further allows a user to aggregate historical data and model future dose rules to assess predicted fire rates. A real-time dashboard assesses alert effectiveness and user response. The initial trial consisted of twenty-three commonly ordered drugs.

Results

After 15 months, only 24% of dose range alerts were overridden. For acetaminophen, the sensitivity of alerts increased from 5.2% to 100%, and the percentage of alerts changing provider practice rose from 43.9% to 97.8%. Overall the number of alerts per day for acetaminophen decreased from one per day to one every three days. The next most frequently alerted medication was morphine, accounting for nearly 17% of the total; of these, 7.8% were for orders exceeding recommended maximal doses.

Conclusion

Creating robust dose range checking requires careful planning to develop effective dose rules. Utilizing a real-time dashboard to monitor alerts helps assess and reduce alert fatigue. Quick changes made by content experts (pharmacists and physicians) with the custom configuration tool were vital to provider acceptance. Further development is necessary to handle more complex if/else hierarchical dose rules.

Implementing a wireless-distributed EMR for a traveling student-run global health clinic

Emeka C. Anyanwu, MD[1]; Cheryl Thompson, PhD[1]; John T. Gale, PhD[2]
[1]Case Western School of Medicine, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH

Introduction

Since 2009, the Peru Health Outreach Project has offered students and health professionals in Cleveland, OH the opportunity to provide care in the Sacred Valley Region of Peru. Formerly the project made use of paper charting, which was later transcribed in to an electronic spreadsheet. In 2011, the group decided that it could benefit from an electronic record workflow and began to pursue options.

Early Considerations & Constraints

In considering electronic medical record solutions the group took in to consideration the following requirements:

- Independence from stationary power and network infrastructure was essential
- As a volunteer/student-run initiative the solution needed to be extremely cost efficient
- The solution needed to provide data security for our patients and their protected health information (PHI)
- Easy integration into the clinic's dynamic workflow with minimal to little training
- Platform and device agnostic, as the devices used would be volunteer owned and operated

OpenMRS, an open-source medical record system led by the Regenstrief Institute and Partners In Health fit these criteria and allowed us to prototype and deploy our system rapidly

Taking OpenMRS Mobile

To achieve necessary mobility the OpenMRS stack was deployed on a laptop equipped with an additional external battery. Consumer-grade wireless routers were modified to be powered via USB. An alternative firmware installed on the routers allowed the use of wireless distribution system (WDS) protocols to distribute the network over a greater range by linking the routers together creating a mesh network. Data security was achieved by disk and network level encryption.

Our Experience

Over the course of a month more than 1500 unique patient encounters were logged at over a dozen clinical sites. Only a single day of downtime was experienced. EMR kiosks were setup at patient intake, physician encounter, and pharmacy encounter stations. Immediately, the group recognized the gains in efficiency and data quality, including:

- Weekly report generation allowed the tracking and anticipation of medication supplies
- Data workflow adjustments could be made to encounter forms each day as the group saw fit
- Patients requiring further follow-up were more readily documented and tracked
- Data entry for IRB approved research was facilitated by a computer-based workflow

Difficulties & Lessons Learned

Considering the group's success, several critical lessons were learned during this experience:

- There are issues with portability between server computers and software versions of OpenMRS
- Incremental backups of the OpenMRS database are simple to create and restore to the same machine with basic SQL knowledge.
- Wireless network penetration can be greatly improved using mesh-linked consumer routers
- Similar traveling implementations could benefit from a mobile device ready interface as these devices offer greater battery life and portability.
- Installation and maintenance of OpenMRS requires intermediate-advanced technical knowledge, making implementation difficult for even a small traveling clinic
- The OpenMRS project would benefit from continuing its efforts to simplify the implementation process for newcomers through improved documentation

Protecting Patient Data and Maintaining Site Autonomy: Managing Project Access in a Multi-Site i2b2 Database

Nate C. Apathy[1], Abu Saleh Mohammad Mosa[2,3], Kelly J. Ko, PhD[1],
[1]Cerner Corporation, Kansas City, MO; [2]Institute for Clinical and Translational Science, School of Medicine, University of Missouri, Columbia, MO; [3]Informatics Institute, University of Missouri

Abstract

Organizations often establish an enterprise data warehouse then develop smaller databases for specific projects. However, doing so increases the need to manage multiple databases, including access. We developed a secure web application leveraging organizational parameters within the i2b2 Project Management tool to divide users and projects by organizations or sites. Through the secure web application users can now manage access at the project level instead of relying on the hosting institution to manage user accounts.

Introduction

Informatics for Integrating Biology and the Bedside (i2b2) is an open source tool developed by Partners Healthcare, Inc. and the NIH, to help manage clinical data for research purposes. Commonly, organizations will establish an enterprise data warehouse containing all relevant clinical information and then develop smaller databases for individual projects. However, as contributing institutions and projects increase, so does the need for data protection and decentralized management of data access. In order to address this issue, we developed an approach to manage access to a large multitenant database with various disparate projects and unique user groups.

Architecture

Through a secure web application (Cerner i2b2 User Management Tool), institutions can assign user permissions, provide access relevant to the users' role, and monitor user activity. This can be managed across individual users as well as multiple projects at the same site. By leveraging organizational parameters already established in the opensource i2b2 Project Management tool, site administrators can manage i2b2 access for only their institution or projects, while protecting other projects and data associated with other sites, investigators, or data domains (Figure 1).

By democratizing user management, we remove the onus of user maintenance and provisioning from a single, centralized i2b2 resource and allow project teams to maintain project-level access. Project-specific resources (i.e., principal investigator) can now control user access at the project level, rather than having those responsibilities rest in the hands of a centralized resource who may be managing multiple databases, to provision and manage user accounts on their behalf. Doing so helps to expand knowledge of i2b2 at the site level and also increases the efficiency of account maintenance.

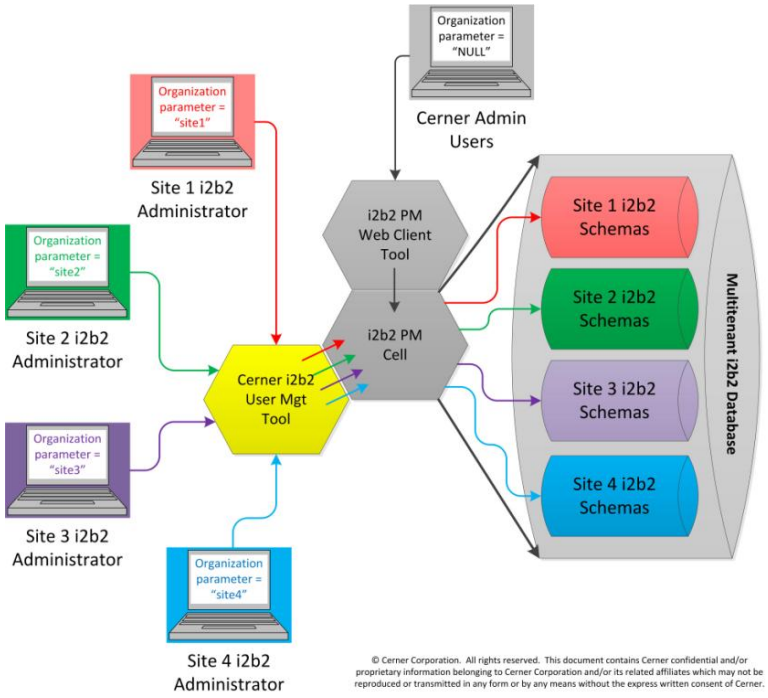

Figure 1. Schematic illustration of Cerner i2b2 User Management Tool architecture.

Conclusion

Although there are many different approaches to protect patient data, managing roles and subsequent access is particularly important when data reside in a single multitenant database. However, managing access across multiple projects through a centralized resource may prove difficult, especially as the number of projects increases. Through developing a secure web application, we are able to manage access based on organizational affiliation as well as role at the project level.

Experimental Protocol to Assess Comprehension and Perceived Ease of Comprehension of Tailored Health Infographics Compared to Text Alone

Adriana Arcia, PhD, RN[1] & Suzanne Bakken, PhD, RN[1,2],
[1]School of Nursing and [2]Department of Biomedical Informatics, Columbia University, New York, NY

Introduction

As part of the Washington Heights/Inwood Informatics Infrastructure for Comparative Effectiveness Research (WICER) project (R01HS019853), we created a series of infographics to return self-reported health data back to the >5,800 survey participants in an easily-comprehensible and actionable format. The purpose of this abstract is to describe an experimental protocol for the assessment of comprehension and perceived ease of comprehension of tailored infographics as compared to text alone.

Experimental Protocol

Principal aims are: 1) to evaluate the efficacy of infographics (experimental condition) compared to text alone (control condition) at aiding participants' comprehension of personal health status in the context of community/aggregate data and/or national standards; 2) to determine if participants' ratings of ease of comprehension are associated with the mode of information presentation (infographics vs. text alone); and 3) to determine what effect(s), if any, age and health literacy level have on comprehension.

Table 1. Stratification by age group and literacy level

Age group	Inadequate health literacy	Marginal + adequate health literacy
18-60	*n* = 36	*n* = 36
>60	*n* = 36	*n* = 36

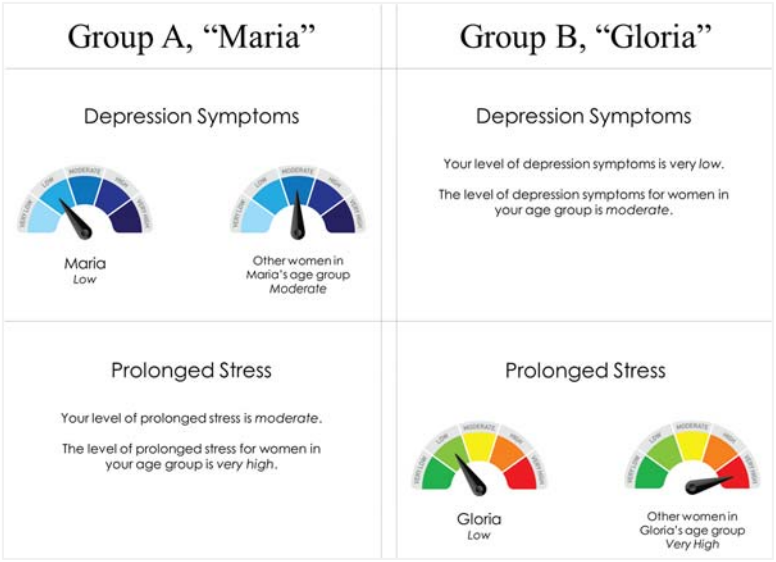

Figure 1. Visually and conceptually similar paired items

We will conduct a controlled trial with stratified randomization. Participants (*n* = 144) will be stratified by age group (18-60 vs. >60) and by health literacy level (inadequate vs. marginal + adequate) (see Table 1) prior to randomization to four groups: A1, A2, B1, and B2. Group A will serve as group B's control, and vice versa; group 1 will see text first, group 2 will see infographics first. For example, group A will be presented with an infographic on depression symptoms and text-only on prolonged stress while group B will be presented with text-only on depression symptoms and an infographic on prolonged stress (see example in Figure 1). Decks of infographic and text-only slides will be tailored for participants with their own survey data. For each slide, participants will complete one or more comprehension questions (e.g., "Is your BMI category underweight, normal, overweight, or obese?") and a rating of the ease of comprehension of the item ("Very difficult" to "Very easy" to understand). Summated comprehension and ease of comprehension scores will be analyzed with *t*-tests; a balanced two-way analysis of variance design will be used to test for main and/or interaction effects of age and health literacy on comprehension scores.

Discussion

The study design features, especially the use of visually and/or conceptually similar matched pairs of infographics, will be employed to maximize scientific rigor and minimize systematic bias.

Finding Different Types of Medical Conditions: From Data Generation to Automatic Classification

Nathan Artz[1], Jinho D. Choi, PhD[2], Stephen Doogan[1]
[1]Real Life Sciences, New York, NY; [2]Emory University, Atlanta, GA

Abstract

One of the challenges analyzing medical conditions in unstructured data is in determining whether they are reported as indications or side effects. Classifying different types of medical conditions enables a deeper understanding of disease manifestation and treatment risk, helping further research in this field. In our study, we collect medical forum posts, annotate different types of medical conditions, and classify medical conditions into indications and side effects using natural language processing and machine learning techniques.

Introduction

When analyzing texts from patient reporting systems (e.g., FAERS, social media), researchers often utilize medical databases such as MedDRA to produce ranked frequency counts of medical conditions[1]; however, this approach fails to differentiate treatment indications and side effect conditions, which is a critical part of assessing treatment outcomes. In this study, we aggregated and annotated social media posts from several online medical forums. We have also developed a novel system to classify mentions of conditions into indication and side effect groups.

Data Creation

We aggregated online medical forum posts from 22 different sources, and normalized them using ETL extraction infrastructure. For this study, we focused on a class of antibiotic drugs, identifying 19,313 posts with mentions of the target treatment entities. We then used a custom medical dictionary (MedDRA in addition to verbatim terms that were manually selected) to identify 5,179 unique conditions across this dataset, and manually annotated a dataset of 760 sentences that contained at least one condition and treatment. Each sentence was then given a binary label indicating whether the condition played the role of an "indication" or "side effect" of the given treatment. Finally, specific treatment and condition mentions in text were replaced by generic text labels (i.e. _TREATMENT, _CONDITION) to prevent overfitting to the antibiotic drug class.

Automatic Classification Approach

Various combinations of syntactic and semantic features are extracted from dependency graphs generated by a NLP toolkit, ClearNLP[2], and used for generating a statistical model trained by support vector machines (SVM). This statistical model is used for classifying medical conditions in raw texts. Figure 1 shows the overview of our approach.

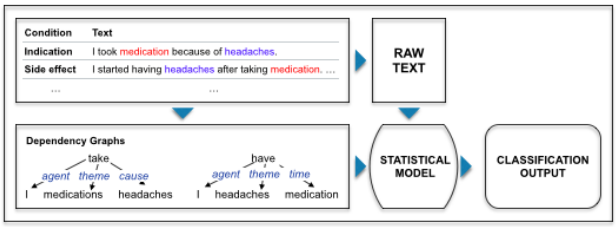

Figure 1. The overview of our classification approach.

Results

We used an SVM classifier with 5-fold cross validation and averaged the outcomes of the folds to determine the F1 scores (see Figure 2).

We manually reviewed some of the most impactful features of the SVM to see which are most important when differentiating the two classes of conditions. For conditions playing the role of indication, we see interesting features such as a Bigram(*treatment*, for) and syntactic_parent(*condition,* for) as in "on steroids for the inflammation". For side effects, we observe features such as SyntacticParent(*condition*, make) or SyntacticParent(*condition*, give) as in "treatment made me sick" or "the drug gave me an allergic reaction" which heavily influence the decision boundary of the SVM.

Experiment	Features	F1 Score
1	Baseline: Bag of Lemmas	78.23
2	Bag of Lemmas + Syntactic Features	84.26
3	Bag of Lemmas + Syntactic Features + Syntactic Roles	83.3

Figure 2. F1 scores for three experiments using different feature sets

Conclusion

We believe this is a feasible approach to differentiating the roles of medical conditions. This approach is suggested for use in spontaneous reports where many of the conditions can be assumed to play side effect or indication roles, versus other texts where the relations between treatment and conditions could be highly variable. Our study can enable researchers and pharmaceutical companies to better monitor health risks for patients by providing, for instance, a means to filter out instances of indications and focus on side effects related information in spontaneous reports. In future studies, we will use use our model to extract indications and side effects across various drug classes and compare our results to existing drug labels.

Linking Provider Documentation to Handoff – the Status View

Phillip Asaro MD [2], Charles H Andrus, MHA [1], Kevin O'Bryan MD [2], Feliciano Yu, MD, MSPH [2]
[1] St. Louis Children's Hospital, St. Louis MO
[2] Washington University School of Medicine, St. Louis MO

INTRODUCTION: The road to effective implementation of electronic medical records remains challenging in most settings. The billing document use-case often trumps clinically oriented use-cases and leads to charts bloated with text that is perceived as necessary for reasons other than clinical care. Effective handoff of patient care from provider to provider is critical to quality patient care and various tools have been developed to assist in the transfer of useful information during handoff. These tools are typically not integrated with provider documentation and require duplicate documentation, further frustrating clinicians.

GOAL: Our overarching goal is the development of a functional framework for provider documentation that supports efficient workflow and optimal information flow, utilizing appropriately visible and enduring information components that integrate patient-care planning, documentation tasks and handoff.

METHODS: We are designing a documentation framework for a complex academic environment in which many of the patients are cared for by multiple clinical services and within each clinical service there may be multiple provider types working in a cooperative hierarchical relationship.

We began by eliciting information flow requirements from a variety of clinical services. We compiled a list of the standard components of clinical notes and supplemented this with additional components required to support the elicited information flows. Documentation tasks considered included History and Physicals, Consult Notes, Progress Notes, Discharge Notes, Off-Service Notes, Rounding Worksheets, and Handoff Sheets. We characterized each information component according the its scope, described in terms of which document types the component will appear in, which provider types would create, edit, and/or consume the information in that component, and durability of information in that component. Then through brainstorming between a software architect and clinicians (the authors), we developed a vision of an intuitive interface for maintaining the information in these components.

THE VISION: The functional framework that emerged is a single-screen integrated interface with context-oriented views. The interface consists of movable widgets that can be selected and arranged as needed according to the current view. Views and widget functionality are further customized according to the needs of each clinical service. Each of the widgets is designed independently with functionality to allow intuitive entry of the data needed for that specific component while meeting billing and regulatory requirements. Differing needs of various services are handled primarily at the widget and view levels. Most of the information components contain information entered specifically by each clinical service, but a few components, related to discharge planning for example, may contain shared information across services.

Typical Use-Cases: When in History & Physical or Consult Note views, information components are selected and arranged approximating the layout of the relevant document. The provider enters the relevant information in each component. When the information is complete, a "Document Save" button is activated producing the History & Physical or Consult document. The following day, before and during patient-care rounds, the Status View is used. This view displays all information components arranged according to user preference. Durable information entered the day before remains in the widgets. Interim history is entered in the Interim History widget. New results are reviewed using the Result Viewer which also allows the user to select results for inclusion in the progress note for the day. Problem Assessments and Plans are updated as needed to reflect the current state of the patient and current decision-making. When ready to create a progress note for the day, the provider selects the Progress Note view, further tweaks any information as needed and activates the Document Save button to create the note. The progress note is thus a snapshot of the current state of the patient's condition and current decision-making related to that patient. Later that day during handoff, a handoff sheet is created utilizing the information from the current state at that time. We believe that this vision will lead to an intuitive user interface in an information-flow-oriented framework that will support management of clinical content via easily configurable and modifiable components.

Reducing Complexity of Breast Cancer Treatment Regimen Representation in Tumor Registries

Ravi V. Atreya[1], Mia A. Levy, MD, PhD[1]
[1]Vanderbilt University School of Medicine, Nashville, TN

Abstract

To rapidly improve clinical decision-making and implement new initiatives in healthcare, we must be able to constantly learn from data generated through the course of patient care. Cancer treatment regimens are complex and must be effectively identified in data found in the electronic medical record (EMR). Tumor registries are curated patient care records and can be used to generate gold standards to better analyze EMR data. In this study, we seek to assess the ability of various methods to reduce the complexity of the treatment regimens stored in the tumor registry. Regimens were stored as strings of successive treatment events and were simplified by removing repetitive treatments and by modeling the order of treatment events. This work demonstrates the ability of basic methods to simplify tumor registry treatment regimens and shows that as regimens grow more complicated, it is important to develop methods to represent them effectively.

Introduction & Background

The rapid learning cancer system concept provides an opportunity to rapidly improve clinical decision making and implement new initiatives to meet financial and quality challenges facing healthcare organizations. In order to accomplish this, it is vital to discover treatment regimens from often complex data in the electronic medical record (EMR). Tumor registries are patient records that curated by nurses and contain data on patients' treatment history. While these registries are difficult to maintain, they contain a wealth of organized data on patients' cancer history. Tumor registries, while complex, can serve as a tool to filter and understand even more multifaceted EMR data. In this study we assess methods that utilize the importance of treatment event sequence to identify and simplify the treatment regimens for patients with breast cancer.

Methods

4,160 records of patients with breast cancer undergoing 16,054 treatment events between 1999 and 2012 were extracted from the Vanderbilt University Medical Center tumor registry. A basic simplification of the data was conducted to merge chemotherapy and immunotherapy events due to shifting registry definitions. Character strings were used to represent treatment regimens where the treatment events (S - surgery, R - radiation, H - hormone, C - chemotherapy) were placed in order of occurrence. Complexity was assessed for two additional treatment regimen simplification methods. First, repeating treatments (i.e., SSSC) were reduced to a single treatment event (i.e., SC). Another method utilized the ordering of the first occurrence of the four therapies (i.e., for SSSC, S occurred before C) to organize the treatment sequences. These methods were assessed by how the new representations were able to simplify the treatment regimens by assessing the count as well as distribution across patients.

Results and Discussion

This work demonstrates how treatment regimens extracted from the tumor registry can be simplified by focusing on event ordering to serve as an effective gold standard for complex EMR data. Using only the order of the first occurrence of treatment events demonstrated the greatest reduction in complexity (figure 1). From 1999 to 2012, the number of treatment regimen representations has doubled, along with the number of new breast cancer patients seen per year. In order to keep pace with the growing complexity of cancer care, it is important to develop gold standards of various levels of complexity to aid in the analysis of EMR data. The methods described here are limited by not incorporating the time between events. Additional work will utilize clustering algorithms to demonstrate the complexity introduced by adding time between treatments.

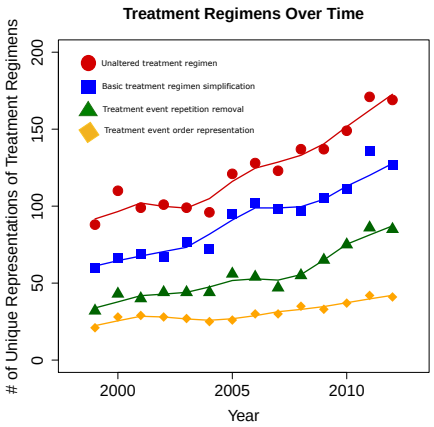

Figure 1: Number of unique representations of treatment regimens over time has increased. Number of patients seen has also increased from 209 in 1999 to 427 in 2012.

Picking a proxy on the web: Interactive Patient Interview Module for Health Care Proxy Documentation

Adarsha S Bajracharya, M.D., [1] Bradley H Crotty, M.D., M.P.H., [1] Hollis B Kowaloff, B.A., [1] Warner V Slack, M.D., [1] Charles Safran, M.D., M.S. [1]
1. Beth Israel Deaconess Medical Center, Harvard Medical School, Boston MA

Problem: When ill or incapacitated, patients may be unable to make their own medical decisions. A health care proxy (HCP) form is a legal document formalizing the appointment of a surrogate decision-maker. Prior studies show that patients who had given surrogate decision-making information to their providers lacked documentation of this in their medical records.(1) (2)Physician reminders alone are not associated with greater HCP appointment, but reminders plus mailings to patients of advance care planning forms and related materials have improved HCP appointment rates.(3)

Solution: We have developed an interactive interview to be available in a patient portal, through which patients can provide health care proxy information. Information provided by the patient will be stored in the patient's electronic medical record for clinician review. This module also has an integrated educational section, that answers common questions, provides background information about the importance of health care proxies, and advises patients how best to discuss their care preferences with loved ones.

Impact: Informed by prior experiences, we will measure the impact of our approach on rates of HCP appointments and the provision of completed of health care proxy forms. Through better information and documentation, we hope to improve care of all patients in line with their wishes.

Screen shot 2: Demographics

Screen shot 1: Patient options

Value Transparency in Health Information Exchange as a Mechanism to Enrich Patient Participation

Gina B. Baker, MSN[1], Shan He, PhD [1], Darren K. Mann [1] Pallavi Ranade-Kharkar, MS[1, 2], Jason Gagner, MBA[1, 2], and Sidney N. Thornton, PhD[1, 2],

[1]Intermountain Healthcare, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT

Abstract

Informing patients of the contributed value for each external datum obtained through Health Information Exchange (HIE) can increase their understanding of data exchange value, encourage their participation, and optimize data validity for clinical use. Values of external data, shown in dollars and patient time, can be inferred from the specific datum's relevance within a modeled care process and the associated treatment activity cost databases. The electronic Patient Visit Summary document can be extended to include itemization of the value contribution for each externally acquired datum pertinent to the encounter.

Introduction

Health Information Exchange (HIE) provides value to the healthcare system via shared data resulting in money and time saved. HIE, however, may also propagate data integrity issues as data are exchanged and integrated. To address these challenges, Intermountain Healthcare, in conjunction with the Care Connectivity Consortium[1], has developed novel HIE services to filter inbound data documents for new or amended data and to logically assess conflict and compatibility for the specific patient encounter[2]. The relevancy of the external data received and resulting value of the specific datum vary depending on the reason(s) and context for the current patient encounter. Patient engagement in HIE, specifically data review and stewardship, provides a way to validate information used in the electronic summary views[3]. To encourage patient engagement and promote data validation an additional section is included in the electronic Patient Visit Summary document. This section provides the value contribution of each data element integrated from an external source and looks much like a shopping receipt showing transactional savings. Recognition of this value presented in familiar units of dollars and time increases patient interest and results in their engagement to validate data thereby increasing its value for future encounters.

Methods

Connections were established between local HIE data processing services, a framework for understanding current patient encounter context, and a repository of treatment-based costs. From these connections logic was developed to compute the value of each externally acquired datum relevant to the current encounter. Then a novel section was appended to the Patient Visit Summary, listing the value contribution of each externally acquired datum in a way that patients and providers can discuss.

Results and Discussion

Prescreening of HIE data for de-duplication and relevancy to the current encounter is helpful to provide a clean record for the clinician and increases value for the use of HIE by patient and provider. While the value of the data changes depending on the clinical context of the current encounter, the section listing value of the data received in relation to the current encounter provides the opportunity for recognition of cost savings associated with HIE participation. This recognition of the role and value of HIE contributes to increased patient participation by verification or correction of data.

Conclusions

The value contribution of each datum originating from external sources can be quantified using time and money measurements and summarized for the current patient encounter. The itemized summary of integrated external data from HIE provides the clinician and the patient insight into the efficiency of the visit.

Implementing SNOMED CT in Laboratory Specimen and Source Tables – If the Shoe Fits…

Pamela Banning, BS (Biology) MT (ASCP)^{CM}, PMP, Elva Knight, BS (Biology) MT (ASCP)
3M Health Information Systems, Inc., Salt Lake City, UT

Issue: Meaningful Use core measures and secondary use in public health reporting require the addition of the SNOMED CT terminology standard to legacy system embedded source and specimen lists. 'Sources' pertain to the anatomic site of concern (e.g. arm, wrist), while 'specimen' pertains to the form delivered to the lab (e.g. swab, aspirate, syringe). Facilities decide mapping scope based on content origination, use case, and system capability.
Method: Four sites submitted separate specimen and source lists in Excel format for terminology mapping. Resources included the SNOMED CT terminology content via the 3M Healthcare Data Dictionary, CliniClue freeware browser, and UMLS. SNOMED CT domain selection guidance was obtained from HL7 and Lab Communities of Practice[1] documents. Specimens were mapped to the SNOMED CT specimen domain. Sources were mapped to body anatomy, substance, or physical device/object domains. Laterality source modifiers were added as needed. Sites clarified ambiguous or nonspecific terms by a question and answer process.
Results: Specimen lists ranged in size from 32 to 111 terms, while source lists ranged from 243 to 995 terms. Both list types had data that crossed domains (e.g. wrist on specimen list; fluid on source list). Successful mapping occurred within all files, but with varying levels of completeness. Completion ranged from 75.7% - 96.7% in each file. Sites may build unconstrained content that is understood and used in their labs but lacks granularity or specificity for standardization (e.g. blue port, bagged, red lumen).

Table 1 - Mapping Examples across SNOMED CT domains

Site Term / SNOMED CT domain	**Body Structure/Substance Physical Device**	**Body Structure Option 2**	**Qualifier**	**Specimen**
Bronchial Washing, Bilateral	955009 Bronchial structure (body structure)	5926001 Structure of bronchial lumen (body structure)	257916006 Bilateral sampling (qualifier value)	122609004 Specimen from lung obtained by bronchial washing procedure (specimen)
Urine, Clean Catch	78014005 Urine (Substance)	--	--	122880004 Urine specimen obtained by clean catch procedure (specimen)

Additional complexity comes from multiple options. A source term of abdominal fluid could map to either:

- 113345001 – Abdominal structure (*body structure*)
- 83670000 – Peritoneal cavity structure (*body structure*)
- 32457005 – Body fluid (*substance*) + 113345001 – Abdominal structure (*body structure*)

By strict definition, a specimen term of abdominal fluid maps to 168139001 – Peritoneal fluid sample (*specimen*)
Conclusions: Full source description is frequently only achieved by combining SNOMED CT concepts (Table 1). Some terms required up to four concepts to provide clarification or best match. Many of the source terms include specimen types, morphologic abnormalities or collection procedures as identified by SNOMED CT hierarchy (abscess, cyst, washing, and lavage). Some mappings fall outside expected domains. The granularity of the terminology standard versus the site data are at different levels. Rebuilding site data may be required to meet standards requirements in the future.

Analysis and Evaluation of methods of similarity in Nutritional Recommendations

Haroldo G. Barroso, Msc[1], Márcia Ito, M.D, PhD[2]
[1]Federal University of Maranhao, Sao Luis, MA; [2]IBM Research Brazil, Sao Paulo, SP

Introduction

A Nutritional Recommendation is understood as a source of information from the Nutrition expert, providing a therapeutic and educational treatment to the patient. Similar cases among patients require an understanding of a whole application domain (Nutrition and Related Pathologies) and their variables (clinical and personal data). For each case we can use some information that was retrieved from similar cases in order to make the nutritional recommendation. [1] This is done through methods of Similarity [2] based on an approach called Case-Based Reasoning. The divergence between the methods however, shows up in the axiom, which directly reflects the behavior of event and performance in the recovery of the same process, leading some methods to achieve further successes in relation to others.

Methods

There are a range of methods of Similarity, in this work, we use: Nearest Neighbor, Contrast model, Simple Matching Coefficient and Probabilistic Model. Although each method has different structures, all of them has the same goal, recover cases, which in turn will receive a nutritional recommendation. All methods are derived from a standard axiom defined by: $S(E, B) * W$

Where we have: S (Similarity Function, final result related to the performance of the method or amount of recovered cases), B (if previously indexed or old), E (Case of entry, to be compared) and W variable (weight, balance in a situation, it is strongly used in all tests). For Analysis and Evaluation of the performance of such methods, by default they use a technique called, Recall x Precision in a situation using 100 cases and assigning values factorial (n!) the weights, in order to validate the tests. This technique considers the points of greatest numbers x minor cases recovered in a situation where it is tested in each case by case method of similarity. [3] In our testing, we found considerable amounts of recovered cases (Σ), where: $\sum^{\text{nearest neighbor}} = \{78,1; 45; 43,1; 39,1; 37,4\}$; $\sum^{\text{contrast model}} = \{45; 43,1; 43,2; 43; 40\}$; $\sum^{\text{simple matching coefficient}} = \{54; 43,2; 43,1; 39,2; 37,6\}$; $\sum^{\text{probabilistic model}} = \{78,1; 58,9; 45; 43,2; 43,1\}$

Conclusions

In preliminary tests, it is concluded that the probabilistic model (Figure 1) reached a more cohesive result, recovering a greater number of cases and show that the methods of similarity have regular and stable behavior, leading to reflect on metrics recovery based not only on satisfactory results, as well as the regular results, avoiding a disparity in performance.

A Proposed Protocol for Meaningful Use Audit Documentation

Robert C. Bell, MS[1], Fengwei Zhong, MD, MPH[1],
Debora J. Simmons, PhD, RN, CCNS[1], Adol Esquivel, MD, PhD[1]
[1]St. Luke's Health System, Department of Clinical Effectiveness and Performance Measurement, Houston, Texas

Abstract
In anticipation of Meaningful Use audits a system standardized, EHR agnostic documentation protocol has been developed to demonstrate compliance with the regulations.

Introduction
The Health Information Technology for Economic and Clinical Health Act (HITECH) put forth incentives for healthcare providers and hospitals to adopt electronic health record (EHR) systems. Along with adoption, "meaningful use" of these systems was specified as a set of goals in order to achieve improvements in care[1]. Meaningful Use started in 2011 and, as currently planned, is implemented in three stages over the course of many years, with each stage increasing in complexity. As a method of regulation of the distribution of incentives, CMS has partnered with Figliozzi and Co. to perform audits of providers and hospitals. There have already been cases where Meaningful Use incentives have had to be completely refunded; Health Management Associates of Naples, Florida reported returning $31M. Many participants are concerned with the lack of knowledge of what exactly triggers an audit[2] and how to demonstrate that the EHR system meets Meaningful Use requirements. To mitigate this risk, it is important to anticipate anything that could be asked for by auditors. To this end a comprehensive audit protocol has been developed that can be used to answer auditors questions, and provide any documentation to prove compliance with Meaningful Use.

Meaningful Use Audit Documentation Protocol
The Meaningful Use audit documentation protocol includes:

- Performance and pre-performance period reports and scorecards[3],
- Extensive supporting documentation for how the system meets the Meaningful Use measures
- The required security assessment and the final report and recommendations,
- Documentation of all Meaningful Use functionality as implemented in the providers' and hospitals' environment,
- Testing of the EHR to ensure that it meets the requirements of Meaningful Use
- NIST (National Institute of Standards and Technology) use case testing[4] performed in the hospitals' EHR system.
- EHR vendor supplied test scripts performed in the providers' and hospitals' EHR system, which verifies that the workflows indicated capture the Meaningful Use required data elements and report them properly.
- The sign off page by executive leadership in the organization.
- The documentation of attestations for Meaningful Use.

A New Approach to Evaluating Mobile Applications in the Emergency Department: Extending Usability Testing and Clinical Simulation

Elizabeth M. Borycki, RN, PhD[1], Andre W. Kushniruk, MSc, PhD[2]
Judith W. Dexheimer, PhD[2]
[1]University of Victoria, Victoria, British Columbia, Canada; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, USA

Abstract

There is a need to use new methodological approaches when evaluating mobile applications for the emergency department (ED). In this work we present one method that can be used to evaluate mobile device use in the ED.

Introduction

Evaluating mobile software applications in terms of their usability and effects on physician and nurse workflow can be difficult in most health care settings, but for evaluators it can be an especially complex undertaking when conducted in settings that are known for their dynamic nature such as the emergency department (ED). In this poster presentation we outline a new "in situ" clinical simulation approach that can be used to create simulated patient cases and to evaluate mobile phone and tablet software specific to an organization's ED visits.

Learning Objective

After reviewing this poster the learner will be better able to evaluate the usability of mobile devices for the ED.

Methodological Approach

In our work we focused on developing a new methodology that can be used to collect usability and workflow data to evaluate the effectiveness of mobile phone and tablet software in ED contexts. We extended Kushniruk and colleagues "in situ" methodology [1] used in physician office and hospital ward settings to collect usability and workflow data and have applied a clinical simulation component to the methodology so that participants in the studies fully experience the dynamic and time limited nature of a typical ED patient visit. In the first stage of the work both typical and atypical cases that are seen in the ED are identified by reviewing visit data and recording the range of patient visits arriving as non-urgent to urgent. Following this we identify typical ED rooms used to treat these types of cases. With the hospital ED organizational context in mind (i.e. the physical structure of the room), we then conduct a thematic analysis of the patient charts that represent each of the above mentioned patient visits to the ED. The thematic analysis is then used as the basis for the development of simulated patients that are similar to real-world ED patients. Therefore, organizational and patient contexts are similar to what a nurse or physician would encounter in an ED. As an added layer, to ensure the ecological validity of the simulated patient cases, we ask ED physicians to review the cases for their representativeness. Therefore, ED visits are used as inputs to the creation of simulated patient cases. Testing is then conducted in an ED room using the simulated patient cases.

Experiences to Date and Discussion

Participants will be trained on the use of mobile phone and tablet software using a face-to-face approach in a classroom setting. After the training is completed physicians and nurses will be invited to participate in the usability testing in a pediatric ED context. Once training is completed a video camera will be placed in the room to record user interactions and communication between the simulated patient (based on our work in reviewing ED visit records) and the mobile device. Screen recording software will be deployed to record participant interactions with mobile devices. The approach is expected to get at the nuances of pediatric care managed in conjunction with software support as compared to other forms of usability and workflow testing of software.

Integrating Diverse HIV-associated Datasets via Semantic Harmonization

William Brown III, DrPH, MA[1,2], Chunhua Weng, PhD[1], David Vawdrey, PhD[1], Alex Carballo-Diéguez, PhD[2], Suzanne Bakken, PhD[1,3]
[1]Department of Biomedical Informatics, Columbia University, New York, NY; [2]HIV Center for Clinical and Behavioral Studies, NY State Psychiatric Institute & Columbia University, New York, NY; [3]School of Nursing, Columbia University, New York, NY

Abstract

The objective of this research is to integrate diverse HIV-associated research datasets. Thus, we have systematically identified and collected HIV-associated datasets based on NIH inclusion criteria and are semantically harmonizing variables across datasets by leveraging controlled vocabularies to formally represent synonymous variables.

Introduction

Integration of diverse HIV-associated datasets has the potential to increase knowledge by increasing the breadth of variables and statistical power critical for analysis, particularly for sub-groups. Thus, integrated analysis can guide the development of novel, high quality, effective interventions for disease prevention and treatment. This topic has been identified as an NIH research priority in the area of HIV-associated data science (RFA-MH-14-200), but few efforts have been made to combine data across HIV studies. To address this gap we have identified HIV-associated datasets based on the inclusion criteria outlined by NIH, and are employing methods of semantic harmonization.

Methods

Datasets were systematically identified using the advanced search form in Clinicaltrials.gov. Four hundred and fifty-three datasets were identified. Eight of 16 investigators who were contacted contributed a total of 17 datasets that met inclusion criteria, representing >4,300 subjects. The UMLS was used to identify controlled vocabularies for formal representation of HIV-associated neurocognitive and behavioral measures, diseases, laboratory results, and medications. Controlled vocabularies (CV) selected include: LOINC [>71,000 measures], SNOMED [>311,000 diseases/measures/medications], RxNorm [medications].

We started the variable formalization process by first standardizing the column, row, and heading format of the data dictionaries of all datasets. We then aggregated all data dictionaries into a variable harmonization table. To find variable related formalisms across different datasets, we used a semantic knowledge resource created by Columbia University, the Medical Entities Dictionary (MED), which is a large repository of medical concepts that are drawn from a variety of semantic knowledge resources including the New York Presbyterian Hospital and the UMLS (i.e. LOINC, SNOMED). The MED browser allowed us to simultaneously identify multiple semantically represented clinical formalisms. We also traversed the semantic structure of the MED to identify relational classifications to other potentially HIV-associated concepts (i.e. Parent nodes, Child node).

Results

The variable harmonization table includes the study ID, variable name, variable identifier or concept data entity (CDE), UMLS-CUI, MED code, LOINC ID, SNOMED ID, and RxNorm. These are further classified by NIH's four target variable classifications: Neuro-psychological, Psychosocial, Behavioral, and Biological/Biomarkers.

Conclusion

Next steps include continued progress towards formalizing >4,300 participants' data and completing the variable formalization table. We will also explore current ontology-based data integration methods.

Development of an Antimicrobial Data Mart from the Electronic Medication Administration Record

Vladimir Bubelev PhD, Brian Myers BS, Jessica Johnston MS, Kurt Stevenson MD, MPH
The Ohio State University Wexner Medical Center, Columbus, Ohio, USA

Abstract: *Monitoring antimicrobial use is critical to the success of Antimicrobial Stewardship Programs (ASPs). We have created a data mart to automatically calculate antimicrobial use metrics based on the medication administration record (MAR) that is readily available to an ASP.*

Introduction: ASP and Information Warehouse (IW) at The Ohio State University Wexner Medical Center (OSUWMC) have partnered to provide access to antimicrobial use data in order to understand antimicrobial use patterns. Antimicrobial use significantly contributes to increasing rates of resistant pathogens and should be monitored at the local level to understand the relationship between antimicrobial use and emerging resistance.

Methods: An Antimicrobial Datamart (AD) was developed based on electronic medication administration records (MAR) and contains two main measures: days of therapy (DOT) and patient days on any antimicrobial (PD). In order to stratify reports by the fields of interest to ASP, the data was grouped by the following: ordering provider, MAR location, clinical service, route and site of administration, MAR date, and medication name. MAR and Admission/Discharge/Transfer (ADT) data were joined in order to report by location. To determine the rate of DOT, a simple proportion was constructed with the numerator as amount utilized and the denominator as number of patients eligible for antimicrobials. DOT is the number of days that a patient is receiving an antibiotic, regardless of dose, frequency, route or number of antimicrobials received on a given day. PD accounts for the receipt of multiple antimicrobials on the same day. When patients receive more than one antimicrobial on the same day, more than one DOT may be counted. Since antimicrobial consumption is directly proportional to the number of patients admitted to a hospital system, and as this number fluctuates, these measures are normalized by dividing by the number of patient-days multiplied by 1,000. Patient-days is the sum of all inpatients at midnight each day. For combining MAR and ADT only the date component of MAR taken date/time stamp for a given MAR was matched with the ADT event window record that spans midnight of the MAR taken date. This method could cause an under-count of DOTs as patients who received an antimicrobial during a given day and were then discharged before midnight of the same day would not contribute to the DOT count since they do not have a corresponding ADT record. Dynamic normalization was used.

Results: The data mart contains 1,477,483 MAR records from Nov2011 to Dec2013. Figure 1 shows an example of select antifungal DOT data.

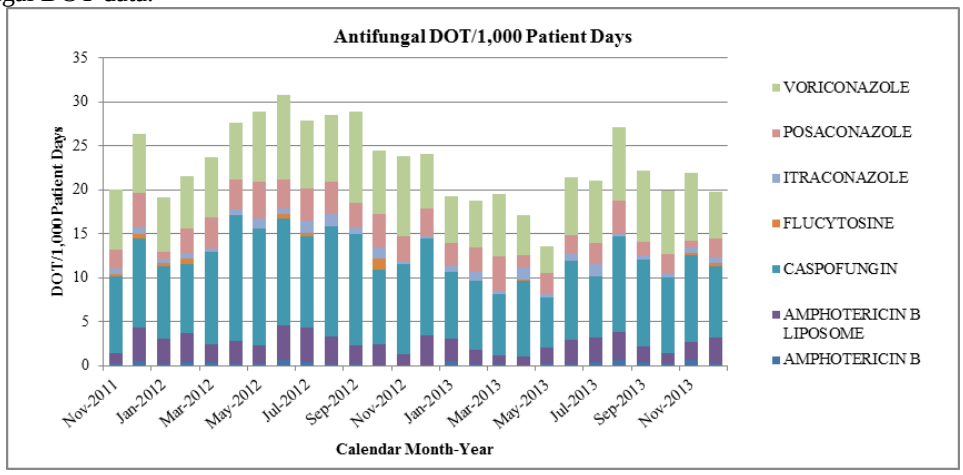

Figure 1. Example of select antifungal days of therapy (DOT)

Discussion: This is an important tool for quality improvement in healthcare as it provides a method for measuring antimicrobial use quickly and reliably allowing for quantification of the direct impact of ASP interventions.

Patient Screening Application to Identify Suitable Clinical Trials

Anca Bucur, PhD[1], Jasper van Leeuwen[1], Njin-Zu Chen[1], Brecht Claerhout[2], Kristof de Schepper[2], David Perez-Rey, PhD[3], Raul Alonso-Calvo, PhD[3], Kamal Saini[4]
[1]Philips Research Europe, The Netherlands; [2]Custodix NV, Belgium; [3]Universidad Politécnica de Madrid, Spain; [4]The Breast International Group, Belgium

Abstract

The population suited to be enrolled in a clinical trial is described by a set of free-text eligibility criteria. The assessment of the eligibility of a patient for a trial requires evaluating whether each criterion is satisfied by the patient information, and is often a time consuming and manual task. We propose a pragmatic and efficient solution to matching the two types of information to evaluate whether a patient satisfies the criteria of relevant trials.

Introduction

Our goal is to automate certain tasks of the patient screening procedure to enhance modern clinical trial recruitment. The application was developed to suit the needs of a large clinical research network in breast cancer. The solution covers the formalization of criteria and of other trial metadata and the efficient management of these representations. We rely on widely-adopted standards to represent the trial and patient information. Our semantic interoperability approach[1] provides shared semantics between formalized trial information and clinical data. This is leveraged by the application to implement automatic linkage and matching of trial criteria to patient data.

The Patient Screening Application

Figure 1 depicts the main components of the application. The front-end component enables the users to visualize available patients and their data, to evaluate for each patient whether they are eligible for one of the trials, to inspect the automatic evaluation results of each criterion and the evidence in the patient file, to update the patient information and to validate or override the recommendations of the system. The underlying Patient Screening service retrieves relevant trial information from the Trial Metadata Repository (TMR), such as the trial criteria and their associated formalism and execution logic. In the TMR criteria are mapped to templates and several formalisms and representations can be associated to a template. The Patient Screening service uses the Criteria Matcher to evaluate the criteria on the patient data retrieved from the Common Information Model (CIM). The CIM expands the set of initial concepts in the trial criteria based on the available domain knowledge representation provided by ontologies (e.g. SNOMED-CT) with relevant concepts whose instances are searched in the available patient data.

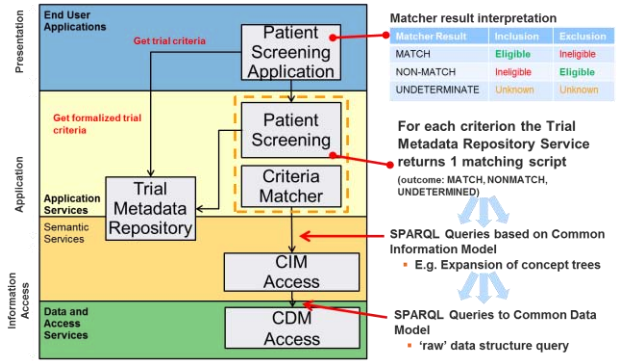

Figure 1. Architecture overview of the Patient Screening application

The application automatically identifies the trials for which a patient is eligible. We combine formal representations of criteria with a pragmatic and efficient solution in which templates are linked to scripts and extensively reused.

Mapping Document Types using LOINC ® Document Ontology: a Case Study

Lindy Buhl RN, BSN[1]; Rachael Seeley RN, BSN[1]; Pat Wilson, RT(R), CPC, PMP[1]

[1]3M Health Information Systems, Inc. Murray, UT

Abstract

A case study was completed on the results of mapping 150 documents for a hospital. The findings were also compared with four previous studies. The case study results indicate the need for further expansion within the type of service and kind of document domains. With the feedback and requests from the industry there has been a constant progression and growth with the Document Ontology axis values in the past decade.

Introduction

The need to send, retrieve, and store health information can be greatly assisted with the coding of document types. Utilizing a universal standard for naming document types allows for information exchange and interoperability of disparate electronic systems[1, 2]. Logical Observations Identifiers Names and Codes® (LOINC®) provides a universal coding system that assists in the identification of related information within electronic messages[2].

Methods

A total of 150 document types from a large-scale hospital were evaluated and mapped using LOINC's Document Ontology. Each document item mapped was ranked by the level of specificity the LOINC code provided. The rankings included; specific, not specific, and not matched. A 'specific' ranking was for a mapped document item which met the criteria in each of the five LOINC document ontology attributes (kind of document, type of service, setting, role and subject matter domain) [1, 2]. With a 'Specific' ranking, the LOINC codes could include null values.

Results

The results of the authors' map based on the institution's use case, were as follows: Of the 150 document types, 98% (147) matched LOINC codes, leaving only 2% (3) that did 'not match'. Of the 147 mapped documents; 19% (28) were ranked 'specific', and 81% (119) were ranked 'not specific'. Of all 147 clinical documents; 17% (25) were mapped to "Note", 11% (16) to "Consultation note", and 7% (11) to "Study report". Also, of the total mapped; 6% had an unspecified provider, 35% had an unspecified setting and 30% had both unspecified provider and unspecified setting. There were instances of multiple site documents mapped to the same LOINC code. Less granular mappings of an institution's document to a LOINC code where less than three LOINC parts matched occurred most often from insufficient content of the Type of Service and Subject Matter Domains.

Conclusion

Industry-wide participation is of the utmost value with actual use cases detailing application of the ontology model, the map findings, and suggestions for improvement. In addition, evaluation of "administrative note" and potentially creating note types such as financial note, financial responsibility note, and various consents is suggested

Leveraging the Electronic Health Record to Identify Prescribing Errors through Rapidly Discontinued Medication Orders

Jonathan D. Burlison, PhD[1]; Lisbeth Bowlin, PharmD[1]; Donald K. Baker, PharmD, MBA[2]; Murad Hasan, MBBS, MS, DrPH[1]; R. Ben McDaniel, PharmD[1]; Jennifer J. Robertson, PharmD[1]; Scott C. Howard, MD[3]; James M. Hoffman, PharmD, MS[1]

Departments of [1]Pharmaceutical Sciences, [2]Information Sciences, and [3]Oncology, St. Jude Children's Research Hospital, Memphis, TN 38105

Background and Objective: Patient safety events, such as prescribing errors, provide learning opportunities to improve patient care systems. Traditional manual methods to identify these events produce incomplete results and are very time consuming, but electronic health records (EHRs) present opportunities to devise new, automated methods that can efficiently detect patient safety events. The "trigger tool" approach (i.e., selectively querying data elements that represent the possibility of an adverse event) has been automated in EHRs, and effectively captures events that are missed using other techniques.(1) The "trigger" *abrupt medication stop* was revised for use in EHRs by Koppel et al., where it was defined as "orders stopped within 120 minutes of being submitted."(2) Through a prospective evaluation, rapidly discontinued orders had a high positive predictive value (PPV) for detecting prescribing errors. We sought to validate this method in a retrospective manner that would allow for efficient ongoing data collection. The purpose of this study was to determine the feasibility and PPV of retrospectively identifying prescribing errors by retrieving and evaluating rapidly discontinued medication orders from an EHR.

Methods: Since 2010, all inpatient and outpatient prescriptions at our tertiary care pediatric hospital have used computerized prescriber order entry (CPOE). A query was developed to extract medication orders from the EHR that were canceled or discontinued within 120 minutes of being originally entered. Using a random number generator, orders from 28 randomly selected days were queried and evaluated as possible prescribing errors. Two pharmacists (LB & BM) reviewed the patient's health record and classified the abrupt medication stop as: 1) *most likely a prescribing error*, 2) *most likely not a prescribing error*, and 3) *not enough information to determine if an error occurred*. Discovered errors were assessed for potential clinical significance and cross-referenced with the hospital's voluntary electronic event reporting system to assess convergence of the two detection methods.

Results: 319 medication orders that were rapidly discontinued were retrieved and reviewed. Interrater agreement was 65% ($\kappa = 0.46$), which corresponds to a moderate level of agreement, and full agreement was reached by consensus in all cases after the reviewers consulted with each other. Roughly half ($n = 154$, PPV = 0.48) of the orders were determined to have been canceled or discontinued due to a prescribing error, 54 (17%) were non-errors and 111 (34%) were indeterminate. The data were divided by time from order submission to discontinuation into 15 minute intervals to examine trends over time. The PPV over time indicated that the trigger was most predictive for orders stopped within the first 90 minutes (PPV = 0.54 vs. 0.21 for 91-120 minutes). None of the detected errors were reported to the hospital's voluntary electronic event reporting system. The 154 errors included duplicate orders ($n = 46$, 30.1%), wrong drug ($n = 20$, 13.1%), wrong route ($n = 16$, 10.5%), and incorrectly ordered ($n = 14$, 9.2%, e.g., forgetting clarification instructions). Some of the errors ($n = 24$) might have been clinically significant had they reached the patient, including significant opioid analgesic dosing errors. 56% of the potentially significant order discontinuations occurred within 15 minutes of original submission.

Discussion: Similar to Koppel et al., our retrospective evaluation of rapidly discontinued medication orders identified many prescribing errors that were not detected by our voluntary error reporting system, and with a high PPV.(2) Along with the ability to detect potentially clinically significant errors, this method can be used to track error characteristics over time, such as error type, prescriber staff position, and drug class. While Koppel et al. demonstrated orders discontinued with 45 minutes of entry had the best PPV, our data indicate prescribing errors can be identified over 90 minutes with an acceptable PPV. Future work will refine this error detection method and seek ways to automate the error detection process even more, without sacrificing predictability.

Conclusion: Rapidly discontinued medication orders can be used to identify prescribing errors that are not detected through other methods. Applying this method retrospectively yielded a similar PPV to previous prospective evaluation, and a retrospective approach allows this error detection method to be used on an ongoing basis to inform systems and process improvement in the prescribing process.

Meaningful Use Stage 1 Clinical Quality Measures: Comparison of Abstracted and Electronic Results

Zahid Butt MD[1], Sara K. Galantowicz, MPH[2], Sam Ogunbo, PhD[1], Ken McCormick[1], Sheryaar Butt[1]
[1]Medisolv, Columbia, MD; [2]Abt Associates, Cambridge, MA

Abstract

There is limited information on how individual measures abstracted from medical records compare, in a "live" setting, to the results generated through fully "re-tooled" electronic specifications. We compared performance of a case matched cohort of 15 abstracted "Core measures" to electronically-specified versions from Meaningful Use Stage 1 for 9 Eligible and Critical Access Hospitals; for ratio measures performance rates at the aggregate level yielded simple correlations ranging from .06 to .94. The continuous measures showed similar variability in correlation.

Methodology:
Nine hospitals were selected from Medisolv's client base that were live the longest with Medisolv end user applications designed to meet clinical quality measures reporting requirements for both CMS (Meaningful Use Stage 1 eCQMs for Eligible Hospitals) and The Joint Commission (Core Measures for accreditation and the CMS Inpatient Quality Reporting Program). Measure results for the abstracted measures were compared to eCQMs in a cohort of case matched patient populations over a six-month period. Correlations of results between the two methods were analyzed first at the measure level and included an aggregate of all facilities. This analysis was supplemented by a facility-level analysis. Performance rates, numerator, denominator and exclusion counts were compared for ratio measures (Stroke and VTE) and median times were compared for the continuous (Emergency Department) measures. The study included all patients 18 years or older at the beginning of the reporting period, regardless of payer and financial class, and discharged between January 1 and June 30, 2013. Because some hospitals use sampling for their abstracted measures, a matched case cohort was constructed comprising patients included in both measure calculations. The entire dataset for the project included 4,657 unique discharges.

Principal Findings:
Direct comparison of performance rates at the aggregate level yielded simple correlations ranging from .06 to .94 for the ratio measures. The continuous measures showed similar variability in correlation. Plotting the aggregate differences for the six months showed the differences to be statistically significant for many, but not all, measures. Analysis at the individual hospital level, however, showed several instances of perfect correlation for some measures, along with considerable variation in correlations across hospitals. Some measures had higher performance correlations across multiple hospitals. A more focused look at the results for one participating facility showed multiple factors may drive observed differences in results including hospital-specific factors, such as abstraction errors, documentation or workflow practices, and measure-specific factors, such as differences (sometimes quite subtle) in measure logic.

Table 1: Reasons for Variation in Hospital I (n=18 cases)

Reason	Frequency
Specification difference	12
Abstractor error	3
Documentation issue	2
Workflow issue	1

Conclusions:
These results suggest that measure "re-tooling" can be successful in a live setting and can replicate results of at least some medical record abstracted measures, provided the specifications match precisely and are implemented properly by the EH/CAHs. Study limitations included the small sample size and the six-month study period. The matched cohort design could also potentially introduce bias in favor of the chart-abstracted measures; this was not tested.

Prior Probability Assessment Wizard

Amos Cahan, MD,[1] James J Cimino, MD[1 2]
[1] Lister Hill National Center for Biomedical Communications and Clinical Center, National Library of Medicine, Bethesda, MD; [2]National Institutes of Health Clinical Center, Bethesda, MD

Bayesian probabilistic diagnosis relies on the clinician's estimated prior or pre-test probability for a disease. However, both overestimation of objective probabilities and poor between-physician agreement raises question about the validity of physicians' confidence judgments as a proxy for the "pre-test probabilities" in the implementation of the threshold approach[1,2].

As real-time, tailored and objective probability estimates are not currently available to clinicians at the point of care, we envisioned a clinical decision support-tool to correct or calibrate physicians' initial estimates. The tool we have developed, the Probability Wizard (PW), serves as a "compiler" that translates a physician-generated differential diagnosis (DD) list into probability estimates through an interactive process. The PW is designed to correct for probability over-estimation by eliminating subadditivity and is also likely to improve between-physician agreement. Starting from a physician-generated DD, the PW leads the physician through a graphic user interface-aided step-wise dialog, resulting in a DD list with numeric estimated probabilities assigned by the PW to each of the clinical entities in the list. Unlike other diagnosis support systems, the possible diagnoses are provided solely by the physician. Clinical validation is needed.

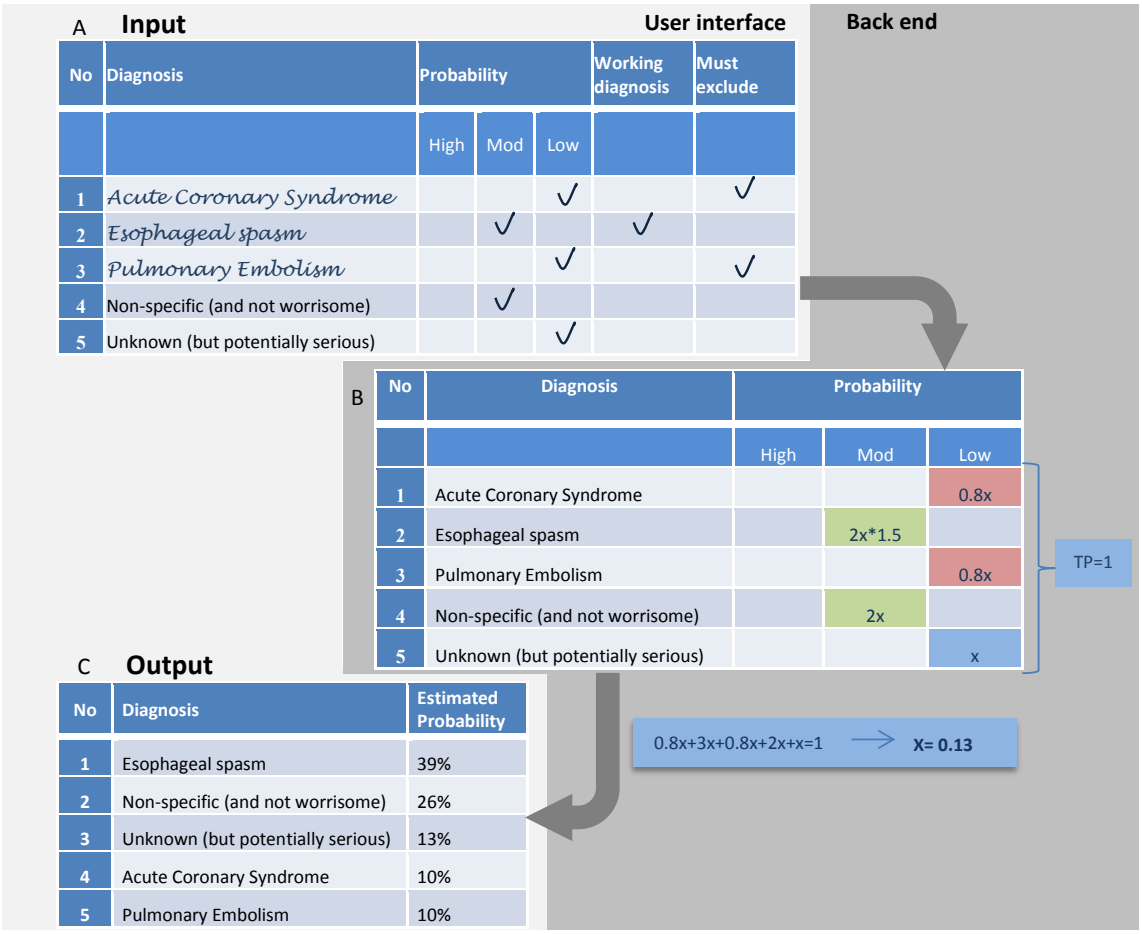

Figure: **Construction of numeric subjective pre-test probability estimates using the Probability Wizard (PW) interface**. In this example, a patient with chest pain is assessed. (A) A preliminary differential diagnosis list is formed by the physician and likelihood categories are checked. Two diagnostic categories are introduced by the PW to account for common clinical scenarios in which there is no specific diagnosis evident, namely "Non-specific" and "Unknown". A working diagnosis and diagnoses which must be excluded are checked if applicable. (B) The sum of all possible diagnoses (TP) is considered to be 1. Correction for moderate confidence (*2), working diagnosis (*1.5) and possible overestimation of the probability of hazardous conditions (*0.8) are applied and absolute numeric probability estimates are computed. (C) An adjusted differential diagnosis list with numeric pre-test probability estimates (in %) is presented to the physician.

Addressing some statistical challenges of using EHR data for clinical research

Fiona M. Callaghan, PhD[1], Dina Demner-Fushman, MD, PhD[1], Swapna Abhyankar, MD[1], Matthew T. Jackson, PhD[2], Mallika Mundkur, MD[1], Clement J. McDonald, MD[1], [1]National Library of Medicine, National Institutes of Health, Bethesda, MD; [2]Food and Drug Administration, Center for Drug Evaluation and Research, White Oak, MD

Abstract

Much has been said about the "big data" potential of large medical databases for clinical discovery, but even after the data are available there are still challenges for statistical analysis. We present two of the challenges here: combining unstructured and manually abstracted data, and imputing or modeling missing or unavailable data.

Introduction

We have conducted clinical projects based on MIMIC-II, a large, comprehensive intensive care unit (ICU) database that includes clinical notes, diagnosis codes, demographics and mortality information[1]. However, challenges remain.

Combining unstructured and manually abstracted data: metformin use and mortality risk in the ICU

We extracted information from clinical notes using natural language processing (NLP) or information retrieval (IR) techniques, and manually abstracted the "ground truth" for a subset of patients. The challenge was whether to use only the NLP/IR information, which is known for everyone but with less than 100% accuracy, or only manually abstracted data which is reliable but represents only a subset of the data, or somehow use a combination of both. We used a statistical misclassification method to combine abstracted and NLP/IR information to predict risk[2]. The estimates of risk, odds ratios (ORs) and confidence intervals (CIs), are more powerful and accurate using misclassification methods than those produced by using manual or NLP/IR data alone[2]. For example, we hypothesized that metformin before ICU admission would lower mortality risk due to its anti-inflammatory properties[3]. Metformin was extracted from admission notes using IR and manual abstraction. The metformin group saw a 70% reduction in risk with the manual data (OR=0.3, 95% CI 0.1-0.6, p=0.003), but a 50% reduction (and narrower CI) when IR and misclassification methods were added (OR=0.5, 95% CI 0.4-0.7, p<0.001).

Missing and/or uncertain data: imputation and modeling

Information may be entered as "unknown" or not entered at all (i.e., "truly missing"). A patient whose information is unavailable on *any* one predictor has all their information removed completely from a multivariable regression analysis, reducing the sample size and often introducing bias. In our obesity study, height (necessary for calculating body mass index) was missing for 25% of patients[4]. We solved the problem by imputing height based on age and gender and checking for bias. However, for another study on race and mortality, race was unavailable for 12% of patients and imputation was not possible. Responses included "declined to answer", "unknown", and "unable to obtain", as well as truly missing. Excluding the unknown race groups was not acceptable as they represented a significant proportion of the data and had a higher mortality rate compared to overall (28% versus 18%). We chose to address this issue by modeling the unknown race values as separate categories, but the work is ongoing.

Conclusion

Large, "real world", medical databases hold great promise for clinical research, but they must be analyzed with care. Often techniques from statistics and informatics have to be brought to bear in order to produce clinical results.

A Data Repository System for Translational Research

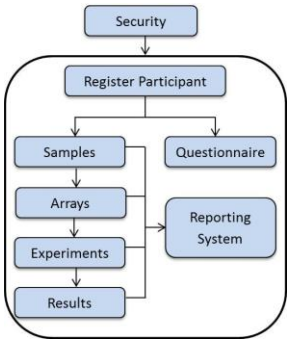
Frank J. Cammarata[1], Leonid Kvecher[1], Hallgeir Rui[2], Albert J. Kovatich[3], Leigh F. Campbell[4], Jeffrey A. Hooke[4], Norman P. B. Joseph[1], Craig D. Shriver[4], Richard J. Mural[1], Hai Hu[1]

[1]Windber Research Institute, Windber, PA; [2]Thomas Jefferson University, Philadelphia, PA; [3]MDR Global Systems, Windber, PA; [4]Walter Reed National Military Medical Center, Bethesda, MD

Abstract: *We developed a Data Repository System to manage, track, store, and process clinicopathologic, biospecimen, and experimental results information for integrative translational research. The system has 7 modules, including Patient, Biospecimen, Tissue Microarray, Experimental Results, and Reports. It takes input from multiple sources and formats and stores the information in a centralized database. The Data Repository System was designed to be secure, flexible, and extendable as the research expands.*

Introduction: A consortium headed by the Thomas Jefferson University, including clinicians and researchers from the Walter Reed National Military Medical Center, MDR Global Systems, and the Windber Research Institute (WRI) was awarded a Komen Promise Grant entitled "Therapy-relevant stratification of breast cancer patients: integrating pathology and biomarker analyses" to study the protein expression of 250 drug targets across 5000 invasive human breast cancer tissues using tissue microarray technology. The clinicopathologic data and sample information were collected at different clinical sites in different formats. The WRI team was tasked to develop an infrastructure system to support the study. We therefore have developed a system to manage, track, store, and process all of this information, including experimental results, to a centralized Data Repository, with multiple reporting capabilities.

Methods and Results: We initially designed an infrastructure composed of a laboratory information management system and a data warehouse system. As the project progressed, the team realized that the ideal design was too cumbersome to support a research project with limited funding. We finally decided to take the approach of developing a data repository incorporating the needed features of the two otherwise distinct systems, including tracking, storage, and reporting. The system was designed to be web-accessible. Java was used to build the graphical user interface and Oracle RDBMS was chosen as the backend database. Figure 1 shows the architecture of the system (A) and a screenshot of a user interface (B). The clinicopathological and sample information, data on tissue microarrays, antibodies, and experiments including high-resolution images and marker expression information as well as subcellular compartment information is collected at the clinical sites and loaded into the system. The accessibility to the data is controlled based on a user's defined credentials for the application. Three levels of reporting capabilities were developed, including data dump, ad-hoc query, and canned reports.



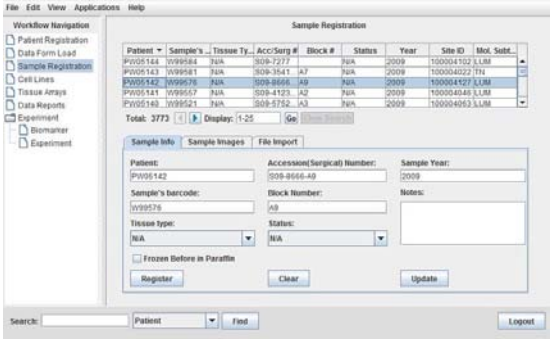


Figure 1(A) Workflow of the Data Repository System.
Figure 1(B) User interface of the Data Repository System.

Conclusion: We have designed and developed a Data Repository System that possesses the important functions of a data tracking system and a data warehouse. It's an innovative light-weight system capable of tracking, storing, and reporting information needed to support a translational research program, that manages information from multiple platforms, multiple sites, and multiple data formats.

The H.O.P.E. Project: Trust and engagement in an online social networking intervention focused on enhancing HIV/STD resilience among African-American youth

Terrance R. Campbell, MA Ed, MSISM[1], Tiffany C. Veinot, PhD[2,3], Alison Grodzinski, MLIS[3]

[1]YOUR Center, Flint, MI, [2]School of Information, University of Michigan, Ann Arbor, MI; [3]School of Public Health, University of Michigan, Ann Arbor, MI

Problem Addressed:
Rates of sexually transmitted diseases among African American youth (aged 18-24) in Flint, MI are among the highest in the US. Our preliminary research regarding the technology-oriented practices of this population identified challenges and opportunities to their engagement with social network-based, digital sexual health promotion tools. We have argued for the value of a trust-centered. Such a framework should address young people's concerns for online safety along with trusted offline networks linkages. Additionally, we note a need to the online experiences to be as compelling as the online "drama" that both engages and repels them.

Specific purpose of the project:
The H.O.P.E. (HIV/STD Outreach, Prevention & Education) project investigates the effects of integrating social media components into an existing evidence-based HIV prevention program for African American youth. The H.O.P.E. project has two components: 1) face-to-face H.O.P.E. parties and 2) H.O.P.E. Online: an interactive website and social media pages. Created by YOUR Center in 1999, H.O.P.E. parties use naturally occurring friendship networks (FSN) to create opportunities for participants to assess their HIV risk, develop a risk reduction plan, and practice communication and decision making skills. Developed by a team of youth advisors, community organizations, and university-based researchers, H.O.P.E. Online includes peer blogs, expert advice, polls, local resource lists, a Facebook page and Twitter feed. This poster presents implementation results from one of our trust-centered design strategies: the use of social media contests to engage youth in disseminating HIV prevention messages and online referrals through trusted social networks.

Methods:
To engage youth in H.O.P.E. online, we conducted three social media contests that operationalized elements of our trust centered design framework, including strategy (participation and network embeddedness, and positive social influence) and functionality (offline networks and collective action). The first contest rewarded youth for posting content on the H.O.P.E. website, and for disseminating messages through Facebook and Twitter. The second contest focused on leveraging HOPE online participants' social networks to increase traffic to the website, Facebook and Twitter pages using text messaging, email and Facebook and Twitter inboxes to refer friends. The third contest rewarded both online activities and referrals. Contests were promoted at H.O.P.E. parties, via postcards to former party participants, and through H.O.P.E. online. We tracked participants' activities and awarded points per activity. For the first contest, all participants received a $10 gift card when they earned 50 points. The two contestants with the most points received $50 gift cards. For follow up contests participants were rewarded points based on referrals and activities. Participants with the most points were awarded $30 gift cards.

Results:
At a 3 month post party follow up survey, approximately 15% of H.O.P.E. party participants reported using the H.O.P.E. website or participating in other online activities. However, the overall contest period (following the 3 month follow up survey) was accompanied by a 103% increase in website visits and a 35% increase in the number of online participants; to include Facebook and Twitter (Shares, comments and retweets). Roughly, 54% of contest participants joined the Facebook page, 30.5% followed H.O.P.E. on Twitter and 27% used text messaging to send messages to H.O.P.E. staff and to their friends. Many also indicated this was the preferred this method of contact for follow ups. Yet, the number of new participants and online activities fell with successive contests and after the completion of all contests.

Conclusions:
Our findings suggest that social media contests can be an effective, trust-centered approach for increasing African American youth engagement in online HIV/STD prevention. These findings add implementation experience to previous theoretical literature regarding the potential role of trust enhancement in technology adoption and usage. Notably, however, the lack of sustained increase in usage over time suggests a potential ceiling effect, diminished interest over time, or the ongoing need for financial incentives. However, strategies for sustained engagement over time are needed; perhaps alignment with participants' daily routines or that of one of their FSN could assist. Additionally, we require insight into participants' subjective experiences of trust and safety while using the intervention. We will investigate these issues in our ongoing research.

Use of Enterprise Clinical Decision Support Infrastructure to Implement Pharmacogenomics at the Point of Care

Pedro Caraballo, MD, David Blair, MD, Michelle Elliott, MD, Robert Bleimeyer, John Crooks, Donald Gabrielson, PMP, Gaurav Jain, Wayne Nicholson, MD, PharmD, Charles Pugh, Padma Rao, Cloann Schultz, PMP, Lynn Summerlin, Joseph Sutton, Carolyn Rohrer-Vitek, Kelly Wix, PharmD, RPh, John Black, MD, Mark Parkulo, MD
Mayo Clinic

Abstract
Human cognition alone is insufficient to implement pharmacogenomics at the point of care. We report our progress accelerating translation of pharmacogenomics guidelines into clinical practice. We are using an enterprise clinical decision support infrastructure and adapting current functionality of commercially available electronic medical records to develop and implement several drug-gene interaction rules. We also combine the CDS alerts with additional educational efforts by using direct links to web resources.

Introduction
Pharmacogenomics (PGx) has the potential to positively impact the prescribing behavior of clinicians. Computer-based clinical decision support (CDS) integrated in the electronic medical record (EMR) could be used to support the implementation of the complex and increasing PGx knowledge. However, current commercially available EMRs have not been designed to implement PGx. We present our efforts to customize our EMRs and enterprise CDS infrastructure to implement PGx across our diverse clinical practice.

Enterprise Clinical Decision Support Infrastructure
Mayo Clinic is committed to promote and coordinate common development, implementation, evaluation, and maintenance of computer-based clinical decision support across the continuum of care. We utilize the operational infrastructure supporting real-time CDS integrated in commercially available EMRs to implement PGx alerts at the point of care. We have two main EMRs, Centricity Enterprise and Cerner Millennium with their respective integrated rule expert systems, Blaze Advisor and Discern Expert. These systems allow Mayo experts to represent knowledge, and develop, deploy and maintain clinical rules to improve quality of care and efficiency. These rules are developed by a multidisciplinary group including clinical experts, pharmacy informatics, nursing informatics, system engineers, software developers, and others, to define the functional and technical specifications of the clinical rules. Extensive inclusion and exclusion criteria are utilized to minimize incorrect or excessive alerts and to avoid alert fatigue. Transactional data associated to the alerts are collected to assess performance and clinical impact of the rules. This program has been very successful implementing multiple CDS rules across Mayo enterprise.

Pharmacogenomics at the Point of Care
Our institution has established the Center for Individualized Medicine and the Pharmacogenomics Task Force to accelerate the implementation of genomic science into routine clinical practice. Working together with the CDS Program, we have several drug-gene interaction rules at various levels of development and implementation across the enterprise (*HLA-B*57:01*-abacavir, *HLA-B*15:02*-carbamazepine, *TPMT*-thiopurines, *CYP2D6*-codeine/ tramadol/tamoxifen, *CYP2C19*-clopidogrel, *SLOC1B1*-simvastatin and *CYP2C9/VKORC1*-warfarin). We are adapting current commercial EMR functionality to accommodate the following specifications: 1) Alert provider if PGx testing is required before prescribing specific medication based on current clinical guidelines. 2) Transfer structure PGx test results to the EMR or capture outside results at the point of care. 3) Document in the problem list or allergy module the relevant genotype/phenotype. 4) Notify ordering provider of the PGx test result by special inbox which contains the genotype/phenotype and specific instructions related to drug-gene interaction. 5) Alert prescribers of a significant drug-gene interaction when ordering specific drug. 5) Provide a web-link in the inbox and alert to additional educational resources in an easy to use Q&A format (AskMayoExpert).

Conclusion
The complexity of PGx requires computer-based aids to become actionable in routine clinical practice. Commercially available EMR systems can be adapted to implement basic gene-drug interactions but more complex genomic data and multi-gene/multi-drug guidelines may require additional development of EMR functionality.

Adopting a Collaborative Program Evaluation Model to Aid Administration and Evaluation of a Large-Scale Public Health IT Grant

Jonathan H. Cardwell, MS[1], Kristina Doing-Harris, PhD[1], Megha Kalsy, MS[1], Wu Xu, PhD[1, 2, 4], Jennifer H. Garvin, PhD, MBA, RHIA[1, 2, 3]

[1]Department of Biomedical Informatics, [2]Division of Epidemiology, University of Utah, Salt Lake City, UT; [3]VA Health Care System, Salt Lake City, UT; [4]Utah Department of Health

Abstract

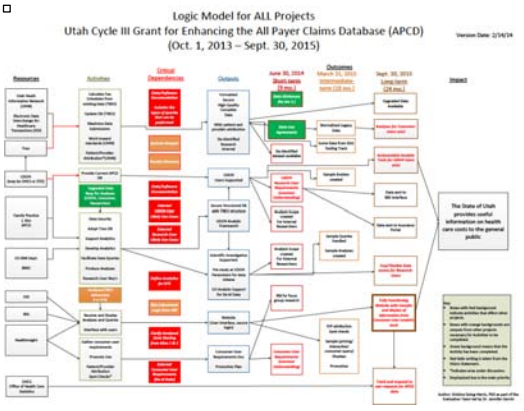
We adopted the Model for Collaborative Evaluations (MCE) developed by Rodriguez-Campos[3], as part of program evaluation for a large-scale, federally funded information system improvement project with the Utah Department of Health. In this poster we describe the use of logic models to facilitate application of the collaborative evaluation model. Reception has been mixed with the use of logic models particularly well received. This feedback indicates that ongoing communication about evaluation goals is necessary.

Introduction

Many projects in IT and Health IT are often not successful in development stages[1,2]. In order to have the best chance of success, we chose a collaborative evaluation model that involves a substantial degree of interaction between evaluators and stakeholders[3]. This approach is unique among evaluation models in that collaborative members (CMs) are stakeholders that work jointly with evaluators to help achieve the overall project and evaluation vision[3]. These CMs are members of relevant groups that provide immediate contribution and feedback throughout the duration of the evaluation. Through the use of collaboratively developed logic models, CMs are actively engaged in understanding the components of the complicated projects through a logic model, which include inputs, critical activities, outputs, and outcomes, both from their own groups' perspectives and with respect to the "big picture" or overall project perspective. We present our current progress in the use of the MCE in a large-scale public health IT project. We work with the Utah Department of Health on the "Enhancing Utah APCD for Healthcare Cost Transparency Cycle III" grant. We iteratively produced logic models for each Aim's work group, along with an overarching logic model for the entire Cycle III grant. The overall goal for the Cycle III grant is to improve the Utah All Payers Database[4] by producing online pricing/cost transparency reports for consumers, employers, researchers, and the general public in Utah. The grant consists of three Aims, each with their own scope and deliverables and also inter-depended with each other. The three aims relate to data quality and security, IT infrastructure, and dissemination.

Methods

Using the MCE requires a cyclical interaction with CMs providing feedback throughout the process. MCE goals include "identifying the situation," "clarifying expectations," "establishing a shared commitment," "ensuring open communication," "encouraging best practices," and "following specific guidelines." To facilitate these goals, logic models are collaboratively developed. Evaluation team members use grant documents as reference points, observe and participate in grant meetings, and review vision statements and work plans to create initial Logic Models. These models depict inputs, critical activities, outputs, and outcomes (see an example in figure 1). Logic models are shared through individual and group meetings with CMs and iteratively refined. Each model is refined until no additional feedback is provided. Success is measured by tracking our evaluation questions throughout the program, such as monitoring the use of best practices in large-scale Health IT implementations and data quality, tracking security and privacy, and facilitating best practices in dissemination – all of which is part of our evaluation plan.



Results

The current overall logic model for all Aims in Cycle III is shown in figure 1. Three other models have been developed for the Aims themselves. We solicited viewpoints from the principle investigator and the leads for each aim regarding the evaluation model as part of our formative evaluation process. Satisfaction with the model and understanding of the use of it are mixed, half of the respondents, who provided a response, found the process useful, a quarter were ambivalent and a quarter found the process intrusive. This feedback indicates that ongoing communication about evaluation goals is necessary. Several expressed that the logic model and collaborative model provide "valuable guidance" for "what tasks/activities need attention." In addition, others reported being unclear about the role of the evaluation team and appeared to understand that the team should be "focusing on an evaluation of the impact of the project."

Conclusion

Collaborative member engagement is a transformative methodology in aiding administration of the development of large-scale public health informatics systems and tools. While the collaborative model is in alignment with and can compliment project management efforts, and that the model supports the best practices of HIT, there is important clarifying communication about the goals of the collaborative evaluation model that needs to be provided on an ongoing basis.

Acknowledgements

We thank the members of the Utah Cycle III for their engagement with the program evaluation team. This publication is funded by CMS Grants to States to Support Health Insurance Rate Review and Increase Transparency in Health Care Pricing, Cycle III [Grant Number: 1 PRPPR140059-01-00], through a subcontract with Utah Department of Health Office of Health Care Statistics.

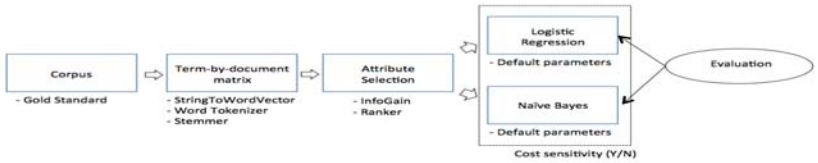
Improving Case Management via Statistical Text Mining in a Foster Care Organization

Arturo Castellanos, Alfred Castillo, Monica Chiarini Tremblay PhD
Florida International University Miami, FL

Abstract. Every year more than 800,000 children in the U.S. spend time in foster care. About 35% of these kids are administered psychotropic medication. An increasing ratio of foster care children per caseworker makes it challenging to balance their multiple roles during the lifecycle of a case. Although there are review boards for identifying cases that require special attention, reviewing all the information is time-prohibitive. This task is further complicated by poorly written, or incomplete, case note entries from the overwhelmed case workers. As part of a comprehensive study with a technology-savvy foster care organization, we investigate a challenging nationwide problem of monitoring and auditing children on psychotropic medication; an issue that has led, in some instances, to, unnecessary deaths as a result of over-prescriptions or concomitant medication. Often, the needed information to identify these cases exists in unstructured data (e.g. home-visit notes from three different foster care agencies), but is difficult to disambiguate due to the sheer size and amount of text in these records. We illustrate how Statistical Text Mining (STM) help complement current practices in classifying and prioritizing cases of psychotropic drug use. This would significantly reduce the load for case managers by providing a smaller sample that highlights children showing evidence of psychotropic drug use.

Methodology. In this study we adopt the CRISP-DM framework—briefly described (see Figure 1 for approach)[1]. The steps in CRISP-DM are iterative steps that include 1) understanding the problem and its context, 2) understanding the data, 3) preparing the data, 4) applying machine learning techniques, 5) evaluation and 6) deployment of results. Each step of the framework is often improved by revisiting a previous step. The first step and second steps are the result of a seven-year research relationship with a leading community based foster care organization. The third step, data preparation activities was to solicit the help of nurse case managers to develop an accurate sample to construct a ''gold standard'' dataset with correctly labeled cases of the binary target variable, psychotropic medication use. Since there is health related information contained in the various case notes we had to follow HIPAA guidelines for personal health information (PHI) identifiers. Children and case identifiers were de-identified by generating a random number and using that number for reference of the child/case. The fourth step requires machine learning of unstructured data, which we did using WEKA [2], an open-source data mining tool. First we tokenized the text in the corpus into a large document-by-term matrix. We used tf-idf to enhance potential predictive terms in single documents in the corpus from the different agencies. Words can be left as is or can be reduced into stemmed words, which are not necessarily linguistically valid words (e.g. bruis: bruise, bruises, bruised). Next, we selected important features using the InfoGain evaluator, which evaluates the worth of an attribute by determining the information gain with respect to the target variable; the ranker then ranks the attributes based on the threshold value we set based on feedback from caseworkers. Also, we need to consider the tradeoff between sensitivity and specificity. Sensitivity is the ratio of predicted children on psychotropic medication to the population of children on psychotropic medication, and specificity is the ratio of the population of children on psychotropic medication –the ratio of children predicted not to be on medication to all children not on medication. We included cost sensitivity to systematically force the algorithms to view the false negatives as a cost function.



Summary of Results and Evaluation. We used Logistic Regression and Naïve Bayes machine learning algorithms with various permutations of stemming {no, yes} and cost sensitivity {no, yes} to develop a total of 8 models (4 per algorithm). The performance of the different models is compared using common metrics such as: recall, precision, root mean squared error (RMSE), F-measure, and ROC curve. Based on statistical results, the Logistic model had a better overall fit for STM than Naïve Bayes by .373 in F-measure. The best performing Logistic model resulted in 322 TN, 30 TP, 3 FN, and 3 FP. The best performing Naïve Bayes model resulted in 276 TN, 30 TP, 3 FN, and 49 FP. Selection of a model is ultimately requires consideration of the different implications in practice. There are models that performed with higher precision, and others that performed with higher recall. In the former, clinical case managers have a lower load of documents to revise at the expense of missing potential positive cases. In the latter, they have a higher load of documents to review with the benefit of including more of the positive cases that are misclassified. For example, the "best" performing model (Logistic in bold) was chosen based on F-measure, but with a recall of 0.909 it actually misclassified 3 children that were on psychotropic medication. If this is deemed unacceptable, then the second Logistic model would be chosen, which resulted in a perfect classification of all children using psychotropic medication (recall = 1.000) at the expense of incorrectly classifying kids that do not take psychotropic drugs.

Precision	Recall	F-measure	RMSE
$P = \frac{TP}{TP + FP}$	$R = \frac{TP}{TP + FN}$	$F = \frac{2(P * R)}{P + R}$	$\sqrt{\frac{\sum_{i=1}^{n}(y_i - \bar{y}_i)^2}{n}}$

Table 1. Formulas for Evaluation

	Precision	Recall	F-measure	RMSE	ROC curve	Stemming	Cost sensitivity
Logistic	**0.909**	**0.909**	**0.909**	**0.103**	**0.998**	**No**	**No**
	0.717	1.000	0.835	0.151	0.998	No	Yes
	0.966	0.848	0.903	0.103	0.998	Yes	No
	0.717	1.000	0.835	0.151	0.998	Yes	Yes
Naïve Bayes	0.323	0.970	0.485	0.408	0.970	No	No
	0.267	0.970	0.418	0.468	0.970	No	Yes
	0.378	**0.909**	**0.536**	**0.366**	**0.971**	**Yes**	**No**
	0.327	0.970	0.489	0.409	0.971	Yes	Yes

Future Research and Next Steps. The initial results are promising and show the potential of significantly minimizing the workload of caseworkers in foster care organizations. In addition to using standard metrics, new metrics should be also explored for evaluation (e.g. how much time it saves the case workers).

Integrating Information from Unstructured Text with Structured Clinical Data from an Electronic Medical Record to Improve Patient Cohort Identification

Victor M. Castro MS [1], Sergey Goryachev MS [1], Christopher D. Herrick MBA [1], Vivian S. Gainer MS[1], Martin Rees BS[1], Shawn N. Murphy MD PhD [1,2]

[1]Partners Healthcare System, Charlestown, MA; [2]Massachusetts General Hospital, Boston, MA

Background - The availability of large-scale electronic medical records (EMR) enables the rapid identification of patient cohorts for research using phenotypes derived from clinically-collected data. The Informatics for Integrating Biology to the Bedside (i2b2) framework provides software tools construct patient queries based on specific inclusion and exclusion criteria[1]. Historically, clinical data available to run these queries originate from diagnosis and procedure billing codes, electronic prescriptions, lab test results, and other structured data sources. Since these data were not collected specifically for research purposes, however, they are often incomplete or lacking in detail. EMRs have a wealth of historical unstructured data in the form of text reports and clinical narratives that have been largely under-utilized to identify patient cohorts. A number of recent efforts have developed natural language processing pipelines to extract information from clinical narratives. In this work, we leverage one such NLP pipeline to extract free text diagnosis and medications from inpatient discharge summaries, map these results to common controlled vocabularies and develop a metadata hierarchy to enable researchers to query the NLP results along-side the structured results using the i2b2 query tool.

Methods – A total of 12,122 discharge summaries for 10,502 patients from two large tertiary care hospitals in Massachusetts were obtained for NLP parsing. The notes were parsed using the UMLSMapper, part of the HiTex NLP pipeline[2]. Text fragments were mapped to either an ICD-9-CM diagnosis or an RxNorm medication. These vocabularies are already in use to query medication and diagnosis data. Negated phrases were tagged as such and included in a separate hierarchy. Mappings were pruned to exclude non-specific mappings (i.e. “evaluation”, “temperature”, “tear”) which occurred often in the text but did not provide much semantic value. In addition, to remove any possible PHI from the results, we pruned mappings that were based on common proper names from the US Census (i.e., “Evan” mapped to Evan’s Syndrome was excluded). The results were loaded into an i2b2 data mart alongside coded diagnosis and prescriptions billing and prescribing data sources allowing researcher to build queries in the i2b2 query tool using both data sources. Finally, we evaluated the performance of the NLP pipeline on a subset of NLP-extracted diagnosis by comparing structured ICD-9 admission and secondary billing codes associated with each inpatient admission. In addition, we used coded medication reconciliation data at admission and discharge available for a subset of discharge summaries to validate NLP-extracted medications.

Results - We successfully extracted 376,716 disorders mapped to 2,244 distinct ICD-9 codes. The most common diagnosis extracted was Essential Hypertension (ICD-9 401.*) identified in 56% of discharge summaries. 19.7% of the mapped text diagnoses were identified as negated by the NLP process. In addition, 405,613 medications were extracted and mapped to 5,753 distinct RxNorm medication preparations. The most common extracted medication was Aspirin (RxCUI 1191). Initial validation results of extracted diagnosis and medications demonstrated a high-level of accuracy. However, a large number of NLP-extracted diagnoses did not have corresponding billing diagnosis indicating the extracted terms provide greater sensitivity at enumerating a patient’s full problem list during an inpatient admission.

Conclusion – Incorporating diagnosis and medication data extracted from unstructured clinical reports with existing structured data in the EMR improves the specificity and sensitivity of identifying patients in an EMR. We have linked these disparate data sources with existing controlled vocabularies to allow researchers to quickly identify relevant criteria and construct queries across both structured and unstructured data sources without requiring access to PHI. Future work will expand the validation of these results to manually annotated gold standards.

Electronic Implementation of Adolescent Health Guidelines for Preventative Care Transformation: Challenges for the Child Health Improvement through Computer Automation (CHICA) System

David Chartash, BEngSc, MHSc[1,2], Tamara M Dugan, BSc[1], Amy Lewis Gilbert, JD, MPH[1,2], Matthew C Aalsma PhD[1,3], Stephen M Downs MD, MS[1,2]
[1]Children's Health Services Research, Indiana University School of Medicine, Indianapolis, IN; [2]Regenstrief Institute, Indianapolis, IN; [3]Adolescent Medicine, Indiana University School of Medicine, Indianapolis, IN

Abstract

Adolescent health screening, particularly when targeted at mental health, substance abuse and sexual health, is a challenge for pediatricians. We describe how the Child Health Improvement through Computer Automation (CHICA) system offers a unique method of deploying guideline logic for a future clinical trial.

Body

Adolescent screening guidelines are an important component of health maintenance. In the specific areas of mental health, substance abuse and sexual health, they are not well followed. Screening is an essential element of the Patient Protection and Affordable Care Act, which mandates coverage of screening according to the American Academy of Pediatrics Bright Futures guidelines. Pediatricians may not be well prepared to care for this population. Few pediatricians provide comprehensive care to adolescent patients. In primary care, adolescent health service delivery is incompleteand of marginal quality as preventive care of adolescents is demonstrably difficult.

This project seeks to improve adolescent health services related to mental health, substance use and sexual health by implementing the *Bright Futures* guidelines. The Child Health Improvement through Computer Automation (CHICA) clinical decision support system (CDSS) has been effective for collecting structured clinical data and deploying pediatric guidelines, including maternal depression screening and improve targeted screening for disease. We are expanding CHICA to accommodate algorithms in *Bright Futures* for depression, sexual risk and substance abuse.

CHICA is unique in its workflow. It includes a tailored selection of questions to ask patients in the waiting room that inform alerts and reminders to the pediatrician that are selected based on the prioritized needs of the patient. CHICA uses clinical context to prioritize value-based decision support. This logic is achieved through the adaptation of the *Arden Syntax for Medical Logic Systems*. CHICA relies on a hybrid procedural/production rule-based implementation of medical logic modules (MLMs). This implementation allows for the greater facilitation of algorithm based guidelines and serial logic, as well as management of the institution specific "curly-brace problem." This allows for the capturing of clinical context in a data dictionary. Further enhancing the implementation is the use of *PRODUCE* and *CONSUME* modes, which allow for the definition, collection and deployment of structured clinical data and decision support logic, using the same MLM.

The deployment of the medical logic modules for adolescent screening is tied to the use of screening algorithms for requiring both sequential receipt and display of clinical data to perform logical operations. Expanding the CHICA system requires further creation of data which are persistent across instances of skip logic and multi-pronged forking algorithms. Given the automated prioritization of questions, the use of a context driven data model to deal with screening will be a core component of future work.

CHICA is a unique CDSS that uses an adaptation of Arden Syntax to deploy guidelines and store and display data incorporating clinical context. As CHICA is expanded to adolescent screening guidelines, it will be evaluated in a cluster randomized trial evaluating quality of care.

Design of an Online Rabies Vaccination Information System

Jason Chase, MA[1], Isabelle Bichindaritz, PhD[1]

[1]State University of New York, Oswego, NY, USA

Introduction

The Rabies Vaccination System (RVS) was developed to replace the traditional data collection process originally maintained in Microsoft Access. Several key issues with the legacy system such as: limited access; lack of efficiency; and data integrity concerns, made it essential for the development of a dynamic database management system.

Methods

Design of the RVS is comprised of several open-source languages such as: MySQL, PHP, FPDF, HTML5, and CSS3. The system is virtually hosted on a secure network maintained by the Oswego County Health Department. Accessing the RVS within the counties intranet permits authorized user's access through Microsoft Active Directory and remote connections outside the secure network through a CISCO Virtual Private Network (VPN). Two participants were selected for stress testing the newly designed system and have been interviewed to provide system performance and functionality recommendations.

Results

The outcome of implementing the RVS has proven to securely give authorized end-users unlimited access to vaccination data efficiently while enforcing data integrity. The traditional method of data collection required copying data twice before securing it into a database. Data collected at clinics on hand written duplication forms were later entered into the Microsoft Access databases following scheduled vaccination clinics. The RVS provides users at vaccination clinics live access to the vaccination system to enter data once freeing up valuable time while protecting the integrity of the clinical data from duplication errors. Projects related to the RVS prove that data collection processes can be made more efficient, secure, and accessible while creating better work-flow for all users. Another consequence of creating the RVS is that with data collection being performed once, valuable hours at the County Health Department would be saved averaging $500,000 in employment costs in a projected 10 year period by replacing the data entry specialist with the Rabies Vaccination System.

Discussion / Conclusion

Enforcing data Integrity is a key element in any data collection process. Errors in data collection are easily made when it is copied from hand written forms, especially when the forms are written from multiple employees with differing handwriting, and then processed into an electronic record keeping systems by an entirely different employee. The Rabies Vaccination System collects data more reliably than the traditional method utilized by the Oswego County Health Department by collecting data one time. This results in reduced data integrity issues.

Acknowledge

The authors would like to thank the Oswego County Health Department and in particular Stephanie Carmody, ABS for their support and encouragement during this work.

Improving Prediction of Type 2 Diabetes Using Genomic Domain Information

Christopher Chen, BS, Michael A. Grasso, MD, PhD
University of Maryland School of Medicine, Baltimore, MD

Abstract

Incorporating genetic information into type 2 diabetes prediction models has so far yielded little improvement, most of which sum mutations in a linear mutation "score". We present a Support Vector Machine model trained with individual SNPs and domain information: the set of information describing a SNP, such as its locus and potential amino acid changes.

Background

Type 2 diabetes is a worldwide health problem with a high heritability rate and multiple sequellae, including nephropathy, retinopathy, and atherosclerosis. Prediction models for type 2 diabetes take clinical measures as input, such as family history, age, sex, BMI, and metabolic syndrome traits[1]. Because type 2 diabetes is a multifactorial disease with a high heritability rate, adding genomic information should improve prediction performance, but so far has only made marginal improvements.

Most previous prediction models have treated SNPs (single nucleotide polymorphisms) equally. However, SNPs are not equivalent and should be weighted independently. Furthermore, it is possible to increase information content via a SNP's domain information, such as its chromosomal location, its location within a gene, potential amino acid changes, and gene network relationships[2]. We aimed to build and test a Support Vector Machine based prediction model incorporating these two changes: domain information and independent SNP weighting.

Methods

We trained and tested our model using the GENEVA Genes and Environment Initiatives in Type 2 Diabetes case-control dataset, which contained data from the all-male Health Professionals Follow-up Study and the all-female Nurses' Health Study. The sample size included 5875 subjects with 3171 controls, with more than 500,000 SNPs per subject. We picked 32 diabetes-related SNPs along with their domain information, gathered from dbSNP and various journal articles. This produced a final dataset with 5875 subjects each with: 32 SNPs, 13 pieces of domain information per SNP, and 25clinical attributes, for a total of 505 attributes per subject.

We compared prediction models trained using Support Vector Machine with each experimental category: (1) genotype + domain + clinical, (2) genotype + clinical, and (3) clinical only. Algorithms and prediction models were evaluated using average Area under the Receiver Operating Characteristic curve (AROC) in a 10-fold cross-validation.

Results

Our results showed a modest improvement in performance between a model built with domain information versus a model built without domain information (AROC improvement of 0.005). The improvement was small, but consistent and meaningful. This shows that the small amount of domain information we added, especially non-redundant domain information, was the driver for the improvement in performance.

"Doctors who ordered this also ordered…" Automated physician order recommendations and outcome predictions by data-mining electronic medical records

Jonathan H. Chen, MD, PhD[1,2], Russ B. Altman, MD, PhD[3,4*]
1 Center for Innovation to Implementation (Ci2i), Veterans Affairs Palo Alto Health Care System, Palo Alto, CA

Background
National healthcare reforms and incentive programs demand meaningful use of electronic medical records (EMR) to improve patient safety and cost efficiency. This will depend on EMRs integrating clinical decision support (CDS) to drive physician orders (labs, imaging, medications, etc.), the concrete manifestation of clinical decision making. Order sets, risk scores, and similar constructs already help consistency and best-practices, but they are limited by a top-down approach, requiring manual production and limited end-user awareness. A Big Data approach could instead crowd-source clinical expertise from the bottom-up, but it is unknown whether such a data-driven order recommendation system, analogous to Netflix or Amazon.com's "Customer's who bought A also bought B" system, can anticipate real physician orders and clinical outcomes.

Methods
EMR data was extracted from one year of inpatient hospitalizations at Stanford University Hospital (>5.4M structured data items from >18K patients, including physician orders, lab results, and diagnosis codes). Association statistics were counted for all pairs of the ~1,500 most common item types from a random training set of 16,408 patients to derive item-association conditional probability estimates, driving an order recommendation engine. For a separate random test set of 1,903 patients, data occurring within 4 hours of the hospital encounter was used to query for 10 recommended physician orders that were compared against the actual orders occurring within 24 hours. In addition to metrics of recall and precision, inverse frequency weighted variants are introduced to evaluate recommendations that are "specifically relevant" and not just common. The first 24 hours of data for each test patient was also used to query for the conditional probabilities of 30 day mortality and ICU admission within 1 week, which were compared against actual outcomes by ROC analysis.

Results
Compared to a reference benchmark of always recommending the most common items [1], the item-association order recommendation engine improves precision from 26% to 37% ($p<10^{-40}$). Integrating likelihood ratio estimates improves inverse frequency weighted recall from 3% to 17% ($p<10^{-120}$). The framework predicts 30 day mortality and 1 week ICU intervention with ROC AUC (c-statistic) of 0.88 and 0.78, respectively.

Discussion
This data-driven physician order recommendation engine improves upon a reference benchmark in anticipating real physician orders. Different evaluation metrics distinguish common orders from those more specifically relevant to a given clinical context. This same framework predicts clinical outcomes on par with state-of-the-art prognosis scores whose c-statistics range from 0.75-0.90 [2] and 0.69-0.81 [3] for predicting mortality and early ICU admission, respectively.

The key concern with these results is whether their basis on *common* practice patterns represents ideal ones. Prospective trials will be necessary to answer this and many important clinical questions in the pursuit of evidence-based decision making. The inevitable reality of everyday clinical practice however is a perpetual gap of prospective data, resulting in routine dependence upon individual expert opinion and anecdotal experience. Tools as described in this work can still elevate clinical decision making to a *data-driven* process based on the experience of thousands of practitioners from real-world settings in the Big Data era of EMRs.

Indoor Location Awareness by Analyzing Ambient WiFi Signals in an Urban Setting – A Feasibility Study

Mike LC Chen, MD, Chia-Wei Lin, MS, Polun Chang, PhD
Institute of Biomedical Informatics, National Yang Ming University, Taipei, Taiwan (ROC)

Abstract

We conducted a pilot study to explore the feasibility of achieving indoor location awareness in a typical residence setting using off-the-shelf Android devices simply by analyzing ambient WiFi signals. We developed a sniffer program on Android platform to record ambient WiFi signals in different rooms, and demonstrated that the location of an Android device can be determined by comparing detected WiFi signals with previously recorded data.

Introduction

Activities of Daily Living (ADLs) is a term commonly used in health care referring to daily self-care activities such as eating, dressing, grooming, toileting, and functional mobility[1]. Clinically, ADLs are evaluated through subjective questionnaires[2]. Since functional mobility is the foundation to most self-care activities[1], a decline in functional mobility may be related to declining ADL scores. A subjective measure of functional mobility may be established by monitoring an individuals movement patterns at home. Previous work on indoor location tracking involved sophisticated and often proprietary equipment, such as infrared sensors, pressure sensors, cameras, and wireless beacons[3]. In this study, we explored the possibility to achieve location awareness at room level precision using off-the-shelf smartphones and just ambient WiFi signals.

Method

The study was conducted in a 3-bedroom apartment residence, on the 15th floor of a 17-story building in Taipei city. A room-by-room WiFi signal sweep was performed using an Android sniffer program developed in-house. The program is designed to repeatedly scan for all detectable WiFi access points' (AP) signals in a given room, and to record their MAC addresses. The signal sweep was repeated every 5 seconds for 50 times in the bedroom, the living room, and the study. The collected data was used to construct a room-by-MAC address probability matrix, depicting the probability of detecting a signal from a specific AP in a given room. Data collected from a separate round of WiFi sweeps were used as test data. The probability of detecting a signal from a given MAC address was looked up from the probability matrix, the results were added up to determine which room the test data was collected.

Result

For building the probability matrix, 2849 AP signals were detected during 150 signal sweeps (50 times in each room), consisting of 73 unique MAC addresses. Some signal was detected constantly across all 3 rooms, while many other signals were detected in only one or two rooms. A room-by-MAC address probability matrix was constructed. Location was determined correctly 13 times out of 15 test cases (Accuracy: 86.7%). One test case in the living room and another in the bedroom were mistakenly interpreted to be in the study.

Conclusion

Location awareness is only a first step towards establishing a quantitative measure of ADLs. Our study demonstrates the possibility of achieving indoor location awareness just by analyzing the MAC addresses of ambient WiFi signals. Our approach does not require proprietary hardware. For simplicity, the signal strength (RSSI) attribute, while also easily obtained through Android API, was not used in this feasibility study. A more sophisticated algorithm taking signal strength into consideration may yield higher accuracy.

A Preliminary Study of Coupling Transfer Learning with Active Learning for Clinical Named Entity Recognition between Two Institutions

Yukun Chen, MS[1]; Yaoyun Zhang, PhD[3]; Qiaozhu Mei, PhD[4]; Thomas A. Lasko, MD, PhD[1]; Joshua C. Denny, MD, MS[1,2]; Hua Xu, PhD[3,1]

Department of [1]Biomedical Informatics and [2]Medicine, Vanderbilt University, Nashville, TN; [3]School of Biomedical Informatics, The University of Texas Health Science Center at Houston, Houston, TX; [4]School of Information and Department of Electrical Engineering and Computer Science, University of Michigan, Ann Arbor, MI;

Introduction: Named entity recognition (NER) is a common clinical natural language processing (NLP) task used to identify terms of important categories in clinical documents. Supervised machine learning (ML) methods in conjunction with a significant amount of annotation by domain experts can achieve good performance. However, clinical NLP informaticians need to repeat their effort of building the similar ML-based NER models from different institutions for the same task. Active learning (AL) has been reported to reduce the annotation cost while maintaining the desired quality of the model for NER. We investigated whether we could further reduce that cost using transfer learning under a model built previously for a different institution. We call our study transfer active learning (TAL).

Methods: We used a part of the annotated training corpus from 2010 i2b2/VA NLP challenge from two institutions: Beth Israel Deaconess Medical Center (BETH) and Partners Healthcare (PARTNERS). The BETH and PARTNERS corpora contain 73 notes with 8764 sentences and 97 notes with 7551 sentences, respectively. Our goal was to build an NER model for the target institution using active learning with initial samples selected based on a model built from the source institution's data. The model used conditional random fields (CRF) to extract problem, treatment, and lab test entities. We used annotated data from the source domain and unlabeled data from the target domain. The labels of data from target domain can be used only when they are queried. In this preliminary study we focused on methods to select initial samples from the target domain for active learning. We designed two TAL methods and compared them with a pure active learning baseline:

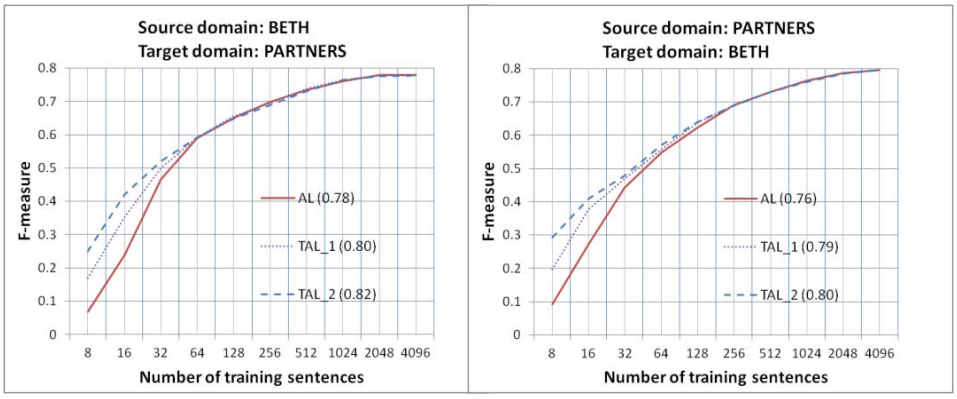
(1) *Baseline (AL)*: a standard active learning process, where initial sentences were selected randomly for labeling to build a CRF, under which the uncertainty of unlabeled sentences was measured by entropy for the next iteration of querying and re-training.

(2) *Full data source model-based uncertainty sampling (TAL_1)*: initial sentences were selected for labeling based on their uncertainty under a model trained using all annotated data in the source domain; we expected this to generate a better initial set of sentences compared to baseline.

(3) *Similar data source model-based uncertainty sampling (TAL_2)*: initial sentences were selected for labeling based on their uncertainty under a model trained using data in the source domain that was most similar to the target domain. The similarity metric used cosine similarity over three types of features: word count, part-of-speech dependencies, and similarity between UMLS concepts. Source-domain sentences were included in the source-domain model if they had a similarity greater than a given threshold to any target-domain sentence.

Evaluation and Results: We ran two TAL experiments: (EXP1) PARTNERS as source domain and BETH as target domain, and (EXP2) BETH as source domain and PARTNERS as target domain. Each experiment used 5-fold cross validation. The learning curve, which plots F-measure as a function of size of training sentences in target domain, is evaluated based on the area under learning curve (ALC) score. Compared to pure active learning, both TAL methods selected more informative sentences for annotation in early training, and the more sophisticated TAL_2 selected better sentences than TAL_1. In later training, where pure active learning had more information available for sentence selection, all three methods approached the same performance. For the ALC scores, TAL_2 (0.82 in EXP1 and 0.80 in EXP2) outperformed TAL_1 (0.80 in EXP1 and 0.79 in EXP2), which is better than AL (0.78 in EXP1 and 0.76 in EXP2). The results were consistent for both experiments.

Discussion: The TAL experiments demonstrate that transferring knowledge from a source domain can benefit data selection for active learning in a target domain. The benefit can be increased by using the most similar subset of data from the source domain instead of the entire set. However, the improvement was limited to an improved starting point of the learning curve. Future work includes investigating methods to increase the slope and asymptote of the learning curve using transfer learning.



Discover Improved-Outcome Evidence for Personalized Treatment from Electronic Health Records (EHR)

Chih-Lin Chi, PhD, MBA[1], Peter Tonellato PhD[2]
[1]University of Minnesota, Minneapolis, MN; [2]Harvard University, Boston, MA

Abstract

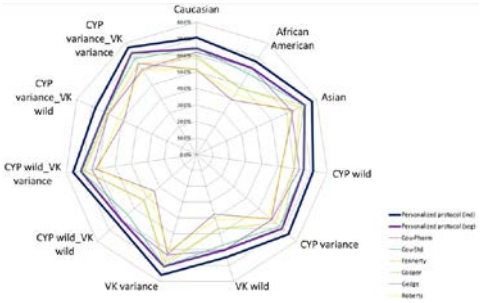
We describe an approach to identify improved-outcome evidence from EHR for optimal personalized treatment. Using personalized warfarin treatment protocol as an example, we identify the protocol option that maximizes outcomes and minimizes risks based on one's clinical and/or genetic characteristics. Results from clinical trial simulation demonstrate that personalized warfarin treatment protocol consistently and significantly improves outcomes from one-fit-all treatment across all patient subgroups.

Introduction

Clinical heterogeneity influences treatment efficacy and, subsequently, results in outcome variations across individuals in one-fit-all treatment settings. On the other hand, there is an opportunity to improve outcomes by currently existing treatments when we understand how clinical heterogeneity influences treatment efficacy and how much difference exists among treatment options. Specifically, we capture the relationship among characteristics, treatment options, and outcomes from electronic health records. With the captured model, we can extract such personalized treatment evidence by examining options that most improve outcome for particular individuals.

Method

The method for evidence discovery consists of three components: prediction, optimization, and production of decision support (DS) rules. We use personalized warfarin treatment as an example to show the method. In this example, we extract such evidence from PharmGKB data, individual-level data with clinical and genetic variables. We demonstrate the three components as follows. (1) Prediction: Clinical trial simulation platform[1] was used as the prediction model. In general, the platform was used to simulate warfarin treatment for a certain protocol over 10 days based on one's clinical and genetic characteristics and drug usage based on a protocol. Finally, the platform was used to predict Time in Therapeutic Range (TTR), which is a surrogate outcome that represents the degree to avoid bleeding and thrombosis when using a protocol for treatment. (2) Optimization: We apply (1) to simulate treatment for six different protocols and predict TTR for each protocol. Due to small solution space, an exhaustive search (an optimization approach) is able to quickly identify the protocol (out of 6 protocols) with the maximum TTR. (3) Production of DS rules: (1) and (2) predict the treatment protocol that maximize TTR outcome for an individual based on personal characteristics. The transparent property of a DS rule, such as the protocol most reduces risks for a certain subgroup of patients, allows easy use of personalized treatment in practical settings. For this component, we first define common characteristic(s) (e.g., African American) of clinical interest and then group patients based on the common characteristic(s). Finally, we identify the protocol that maximize outcome for this subgroup. Discovered evidence was applied to clinical trial simulation setting and we then compare efficacy between personalized protocol and one-fit-all protocol.



Results

Figure shows TTR comparison between two personalized protocols, bold blue (optimize for an individual) and purple (optimize for a subgroup) lines, and six one-fit-all protocols. Compared with one-fit-all protocols, both personalized protocols show consistently and significantly ($P<0.025$) higher TTR (12%~7%) across 11 subgroups.

Conclusion

Without inventing new treatment approach, our research provides another avenue to improve outcomes by identifying personalized treatment option based on one's clinical and/or genetic factors.

Exploring how online communication of cancer patients' symptoms to clinicians affects the changes in family caregiving responsibilities

Ming-Yuan Chih, PhD, MHA[1], Lori L. DuBenske, PhD[2], David H. Gustafson, PhD[2]
[1]University of Kentucky, Lexington, KY; [2]University of Wisconsin-Madison, Madison, WI

Abstract

Online communication of patient symptoms to clinicians may improve family caregiving workload. A latent transition analysis is used to explore this relationship. With the access to an online symptom reporting system that communicates patients' symptoms to clinicians instantly, caregivers are less likely to experience high workload.

Introduction

Family caregivers provide enormous support to those with cancer. As cancer patients' symptoms progress, family caregivers assume more difficult caregiving responsibilities. Communicating patients' symptoms to clinicians online may allow timely support to patients and caregivers, mitigating the rising caregiving responsibilities. A secondary analysis examines the effects of an online reporting system on caregiving workload before and after the intervention.

Methods

In two randomized trials[1], caregiver of advanced cancer patients in the control group were given a web-based system, Comprehensive Health Enhancement Support System (CHESS), designed to support family caregivers and patients.[1] Those in the intervention group were given CHESS plus Clinician Report (CR). CR, a new CHESS service, communicates reported patients' symptoms to clinicians via the Internet.[1] Pretest and 12-month post-intervention survey data from 102 caregivers were analyzed using a 3-step latent transition analysis method.[2] The outcome was measured with the Caregiver Load Scale[3] asking caregivers, "How much time and energy do you spend on the following tasks?" on a 0 (none) to 4 (a lot) scale for these tasks: CLS1: Medical/nursing treatments, CLS2: Personal Care, CLS3: Assistance with walking, moving around, CLS4: Emotional support, CLS5: Monitoring and reporting, CLS6: Providing transportation, CLS7: Managing illness-related finances, CLS8: Additional household tasks, CLS9: Structuring activities, and CLS10: Managing behavior problems.

Results

Two latent classes, high load bearers (HLBs) vs. low load bearers (LLBs), were found at pretest and 12 months (Figure 1). Descriptive statistics showed that male, lung cancer caregivers, whose patients have higher symptom burden, and those with higher physical burden are more likely to be HLBs at pretest—numbers will be presented on the poster. From Table 1, LLBs in CHESS+CR are less likely to become HLBs at 12 months than those in CHESS.

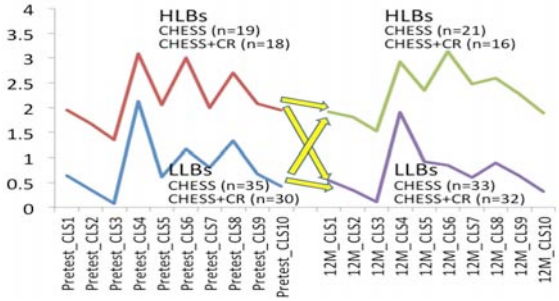

Figure 1. Latent profile plot

Table 1. Transition probabilities

Transition Prob. (Pretest->12M)	CHESS (n=54)	CHESS+CR (n=48)
HLBs -> HLBs	64.4%	62.3%
HLBs -> LLBs	35.6%	37.7%
LLBs -> HLBs	24.8%	15.5%
LLBs -> LLBs	75.2%	84.5%

Conclusion

The lower probability of increasing caregiving load over the 12-month intervention period among CHESS+CR caregivers (15.5%) as compared to CHESS caregivers (24.8%) may be due to the fact that caregivers were more likely to receive timely support because the CR was able to communicate uncontrolled patients' symptoms to clinicians remotely. About 1 in every 3 HLBs at pretest (from both groups) becomes LLBs at 12 months. It is unclear at this point if this is due to the benefits of CHESS overall or to other cancer-related factors.

Cohort-Based Discretization of Continuous Clinical Features to Discover Readmission Risk Factors for Heart Failure Patients

Si-Chi Chin, PhD[1] , Rui Liu, BS[1] , Ankur Teredesai, PhD[1]
[1]Center for Data Science, University of Washington-Tacoma, Tacoma, WA

Abstract

In this paper, we perform retrospective cohort study to validate the use of discretization techniques to discover readmission risk factors for heart failure patients. Insightful and principled visualization techniques may successfully help complex clinical data exploration tasks and aid in the process of knowledge discovery. In this paper, we apply Divide-n-Discover system to visualize and explore clinical data of different cohorts, supporting clinicians to dynamically explore the data and to understand how a given factor may influence the risk of readmission for a given patient. Further, since clinical datasets are nowadays voluminous, and also include large number of continuous attributes, we make use of distributed cloud based infrastructure to scale the dynamic exploration task for the cohort under investigation.

Problem Description

Data integration and understanding is a complex process in healthcare analytics. With the ever-increasing volume of data generated by the Electronic Medical Records (EMR) systems, data analytics in the healthcare domain is facing an overwhelming challenge in recent years. Insightful and principled visualization techniques may successfully help such complex clinical data exploration tasks and aid in the process of knowledge discovery.

Data mining techniques are increasingly used in clinical domains such as predicting risk for a particular disease. However, simply building a better predictive model, traditionally the goal of the data mining community is not enough in these problems. Domain experts are unlikely to trust models that are not understandable or actionable.

To successfully explore the ever-increasing amount of clinical data, we propose using cohort-based discretization of continuous clinical variables, such as age and length of stay, to identify meaningful cut-points for the problem of hospital readmission risk prediction. The proposed cohort-based *Divide'n'Discover* system involves healthcare professionals in the data exploration process and delivers interpretable results. In addition, the cloud based distributed system is designed as a service where both end-users as well as automated applications can submit healthcare data to be discretized.

This poster emphasizes the problem of predicting the risk-of-readmission for heart failure patients within 30-days of discharge, which has received extensive attention among healthcare professionals. However, the system can be extended to a wide range of healthcare problems. Encouraged by the preliminary findings in the prior study, we incorporate a new functionality that allows clinical researchers to dynamically create cohort from a large clinical dataset and visually discover meaning cut-points of the numerical variables of interests.

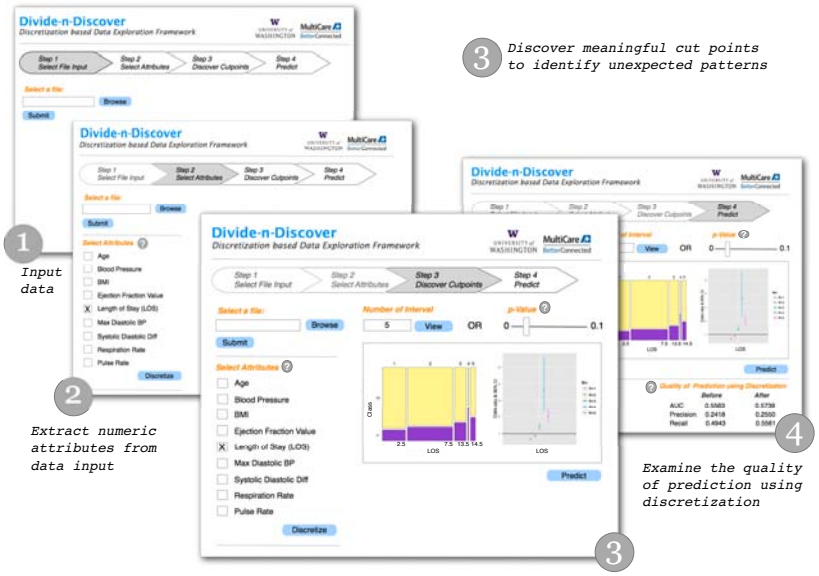

Figure 1. System screenshots of *Divide'n'Discover*.

Utilizing Smartphones to Enhance Urine Strip Test Accessibility

Jason H.D. Cho, M.S., Jacob Guggenheim, B.S., Elizabeth Arcan, B.S., Hannah Friedman, B.S., Shravan Gupta, B.S., Deana C. McDonagh, Ph.D., Joyce K. Thomas, MFA, Bruce R. Schatz, Ph.D.
University of Illinois at Urbana-Champaign, Urbana, IL, USA

Abstract: *Urine strips tests are used by laypersons and hospitals to gauge overall health of patients. From the perspective of laypersons, interpreting urine strip test results is difficult. We conduct preliminary study on accessibility of commercial urine strips that are on the market, identify problems and propose smartphone application to aid interpretation of test results.*

Introduction: Urine strips are used to study the person's health in diagnosing the person's health. These tests are conducted in both clinical settings and consumer settings. The strips test Leukocytes, Nitrite, Urobilinogen, Protein, pH, Haemoglobin, Specific gravity, Ketone, Bilirubin, and Glucose level[1]. These may serve as a good indicator in rapid diagnosis of related diseases[2]. Furthermore, significant number of laypersons buy self-diagnostic tools to gauge their health status. Self testing accounted for $13.8 billion[5] in 2011.

Motivations: We conducted a preliminary user study based on industrial design principles. We noticed two trends. First, asking users to regularly keep diaries of the results of their urine strips seem to have encouraged more health-conscious behavior ("I was very conscious of what I was eating and drinking throughout the day," "This exercise made me more conscious of how much water/liquid I drank each day,"). This type of behavior is also supported in existing health diaries[3] where users also cited improved self-observation as being the motivation for keeping health diaries. Despite these benefits, however, the users had difficulty interpreting the results of the urine strip tests ("I wish I could know what each of the colors of the test strip means"). In order to mitigate these problems, we propose smartphone software to aid interpretation of the urine strips. Naturally, the size of the market and usability, in particular, towards older generation is of interest. 38% of American adults have downloaded a smartphone application in 2011[4]. Even for the older generation, entering diary entries was not a deterrent as long as the software was easy to use[3]. The work further notes that older generations wrote more mobile phone diary entries than the younger generations. This suggests utilizing smartphones to interpret test results is a viable solution.

System Explanation: The goal of the system is to ensure the users do not have to manually distinguish color, and provide intuitive explanation of the results. The users will first take a picture of the urine strip that they have used. The users are then asked to drag the portion of the screen that contains the urine strip. Next, shape recognition detects all the pads used in urine strips. Color recognition is then run, and based on the test results, the system proposes what each pads signifies, along with overall test results evaluation. In order to serve as a user-generated health record, the system also records the test results. We note our program is a standalone software, and does not require any external devices unlike other existing solutions[6]. This allows more laypersons to use the software.

Conclusion: This poster will describe the motivation and system explanation. For our future works, we will evaluate how much the system has improved accessibility in using and interpreting urine test strip results.

Misclassification of cases by querying modality: comparison of ICD-10 codes with clinical laboratory test results

Soo Yeon Cho, RN, MPH, Eun Kyoung Ahn, RN, MPH, Rae Woong Park, MD, PhD
Department of Biomedical Informatics, Ajou Univ. School of Medicine, Suwon, Korea

Abstract

Misclassification is an important bias in observational studies using electronic health records. This study compared case enrollment by two querying modalities: diagnostic codes and laboratory test results. In total, 7,385 cases of chronic renal failure were enrolled by diagnosis and 17,643 by laboratory test results. The number of enrolled cases was significantly different by querying modalities. In the intersection group (n=4,211), mean difference in the start of observation was significant between the two modalities (711±871 days). The querying modality should be carefully considered and evaluated.

Introduction

Misclassification bias is a major concern when enrolling cases using electronic health records (EHRs).[1] Many observational studies have depended on diagnostic codes alone for their case selection. As clinical laboratory test results are beginning to be available in EHRs, a combination of diagnostic codes and laboratory test results could reduce misclassification bias.[2] The aim of this study was to demonstrate the differences in enrolled cases according to the querying modality used: diagnostic codes versus clinical laboratory test results.

Methods

An EHR of a tertiary teaching hospital accommodating 1,201 patient beds was used for analyses. Chronic renal failure was used as an illustrative disease. Two different methods were used for case definition: the diagnosis group, in which ICD-10 codes of clinical classification software (CCS) for chronic renal failure were used (N18, N18.0, N18.8, N18.9, Z49, Z49.0, and Z49.1); and the laboratory group, in which an estimated glomerular filtration rate (eGFR) of <60 $mL \cdot min^{-1} \cdot 1.73\ m^{-2}$ for >3 months was used. The modification of diet in renal diseases study equation was used to calculate the eGRF. Differences in enrolled cases and the start of observation (index date) were compared between the two case definition methods.

Results

In total, 1,933,284 patients >19 years of age were included from July 1994 to September 2012. About twice as many cases were enrolled by laboratory test results (n = 17,643) than by diagnostic codes (n = 7,385). The proportion of female patients and the mean age were significantly higher in the laboratory group than in the diagnostic code group (50.9% vs. 40.9% and 62.1 vs. 57.3 years, respectively; $p < 0.001$ for both). The number of patients belonging to both groups (intersection group) was 4,211. The mean difference in the index date between the querying modalities in the intersection group was 711 ± 871 days. In this group, 881 patients (20.9%) had the same index date, while 742 patients (17.6%) were enrolled earlier by diagnostic codes and 2,588 (61.5%) patients were enrolled earlier by laboratory test results. In total, 156,271 medications were prescribed between the two index dates. Drugs requiring renal dosing for patients with chronic renal failure, such as amlodipine, furosemide, etc., were included among these medications.

Conclusion

The querying modality significantly affects case enrollment in observational studies using EHR data. Because the clinical characteristics of enrolled cases differ significantly according to the querying modality used, careful consideration and evaluation of the querying modality should be used in observation studies using EHR data.

Crowdsourcing and Development of Health-related Pictographs for Minority Groups by Gaming: A Focus Group Study

Carrie M. Christensen cMFA, Qing Zeng-Treitler PhD, Heather Aiono MEd, Bruce Bray MD, Erica Lake MLS, Marty Malheiro MS, Seneca Perri PhD
University of Utah Department of Biomedical Informatics – Salt Lake City, UT - USA

Introduction

We conducted a focus group with diverse members of Community Faces of Utah (CFU), to understand their health information needs and perspectives, and we have incorporated their feedback into the production of a new crowdsourcing game, Doodle Health. The web-based game will be used in the construction of an online library of health-related pictographs.

Methods

Five minority groups comprise CFU: Best of Africa, Calvary Baptist Church, the Hispanic Health Care Task Force, the Urban Indian Center of Salt Lake, and the National Tongan American Society. We conducted a focus group study to assess the health information needs of the minority group members and to obtain their thoughts regarding development of the crowdsourcing game. The two-hour focus group discussion was transcribed and qualitatively analyzed. We took the results of the focus group and met with Roger Alan Altizer, Jr. and his design team. Dr. Altizer is Director of Game Design and Production with the University of Utah Entertainment Arts Engineering Program. He has surveyed the capability of video games to capture the attention of our minds and bodies, providing unforeseen opportunities for individualized health care. [3]. He facilitated the "Design Box", a brainstorming method by which all stakeholders are encouraged to become involved in the game design process. The mobile web-based technologies used to build the game are easily deployable and can run across all kinds of devices and operating systems. HTML5, JavaScript and CSS were the development tools used, and the backend file system uses a combination of PHP and MySQL. During the game, players are given the choice to draw or guess images and the resulting files are sent to a backend study file for moderation/filtering and analysis.

Results

Adding illustrations to medical texts, patient discharge instructions and other health-related education materials can substantially increase comprehension, recall, and adherence rates [1][2]. Pictographs are not universally understood, however, and interpretation can take on a different color from another cultural perspective. The focus group helped the study team identify points of cultural sensitivity. Health-related images or topics that are part of the vernacular for some groups may be offensive or culturally taboo for others. For instance, topics of a sexual nature have to be approached delicately. A member of the National Tongan American Society shared, "Mere kissing was like, taboo, especially in mixed company when brothers and sisters were there. There's this very respectful kind of a thing where certain things are taboo in discussion, to watch or do."

CFU representatives were interested in gaining information about common diseases, such as diabetes and heart disease. And they wished to promote awareness leading to healthy diet and lifestyle choices for their communities. The health concepts people wanted to see illustrated included: nutrition, Body Mass Index (BMI), the cumulative effects of lifestyle and dietary choices on the human body, and comparisons of healthy food verses unhealthy food (including monetary comparisons). They thought that socioeconomic status was an important factor in health. Information about resources and the health insurance market was requested, in order to overcome economic barriers to quality health care. Technological literacy was identified as an area of concern during the focus group. CFU comprises a broad range of people and age groups that have limited experience and access to the Internet. Everyone in the focus group claimed to be using computers, smart phones, and/or tablets frequently, although the younger generation (under 55) is generally more comfortable using digital technologies. Most people have Internet access at home. If not, libraries and other community centers provide access. The participants expressed an interest in being challenged; yet they wanted the game to be user-friendly. They felt that social networking/interaction was a desirable aspect of gaming, and they provided a list of games popular within their communities.

Discussion

Doodle Health is more than an entertaining pastime. The crowdsourcing game might result in a more meaningful resource library of easily comprehended pictographs. During the participatory design process, minority consumers will be able to create/revise and assess the illustrations to ensure the end product meets their needs. The online library will be made freely available to clinicians to supplement text in patient health education materials. The ultimate goal of this project is to have a positive impact on clinical practices by facilitating and enhancing communication between health care providers and patients.

Stage 3 Meaningful Use and Patient-Generated Health Data (PGHD): Outpatient Stakeholder Perspectives on How to Make PGHD Meaningful

Arlene E. Chung, MD, MHA, MMCi[1]; Katherine Treiman, PhD[2]; Carlton Moore, MD, MPH[1]; Christopher M. Shea, PhD[1], Jonathan S. Wald, MD, MPH[2,3]
[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]RTI International, Research Triangle Park, NC; [3]Harvard Medical School, Boston, MA

Abstract: Receiving patient-generated health data (PGHD) is a new measure in the proposed Stage 3 Objectives of the Meaningful Use (MU) Workgroup of the Health IT Policy Committee that would require eligible providers/hospitals to receive provider-requested PGHD, electronically submitted through either structured or semi-structured questionnaires (including patient-reported outcomes) or by secure messaging. A goal of this measure is to enable patients to contribute information to the electronic health record. However, little is known about stakeholders' perceptions of the value of PGHD in outpatient clinical settings.

Objective: To examine key stakeholder perspectives about the utility of the proposed MU Stage 3 objective to receive provider-requested PGHD and explore what workflow or electronic health record (EHR) innovations could help with implementation of this proposed MU objective.

Methods/Evaluation: We conducted semi-structured interviews of physicians, mid-level providers, nutritionists, pharmacists, practice managers/administrators, and nurses from various primary care practices and subspecialty practices at an academic medical center. Interviews focused on several areas: the value of the proposed objective, workflow issues with implementing the objective, EHR innovations needed to meet the objective, and improvement of the objective for implementation. Interviews were transcribed verbatim and then analyzed and coded using qualitative analysis software to identify major themes. Two coders independently reviewed each transcript, and consensus was reached for the predominant themes.

Results: We conducted 45 interviews across five outpatient primary care and subspecialty clinics at University of North Carolina Healthcare System. Overall, participants viewed the prospect of PGHD positively. Many clinics already collected PGHD via screening questionnaires, patient-reported outcomes, blood pressure/blood sugar/weight logs, and patient intake forms in paper format and—in one clinic—electronically. Providers felt that PGHD could be especially useful to track symptoms in patients with chronic conditions or who are actively undergoing treatment regimens such as chemotherapy or radiation. Participants felt the capability to collect these data outside of clinical encounters was valuable since collection between visits and prior to visits could improve efficiency and allow a better view into the patient's health and symptom status longitudinally. Participants did not have concerns about quality of PGHD and did not feel that a certification process was needed for devices used to collect PGHD. However, some had concerns about possible medical liability from receiving PGHD if appropriate follow-up was not provided.

In terms of EHR innovations that could facilitate receiving PGHD, stakeholders felt that various options for modes of collection were necessary to accommodate the heterogeneous needs of patients, including patient portals, in-clinic collection via tablets or kiosks, and interactive voice response systems via telephone. Participants also wanted a way to flag abnormal results and alert providers within the EHR so that appropriate and timely follow-up could be assured. PGHD should be labeled as patient-generated within the EHR so it is distinguished from measured or clinician-entered data from clinical encounters. In addition, patient portal systems should enable the upload of wearable and medical device data automatically via Blue-tooth technology or USB. Meaningful displays of PGHD within the EHR were also thought to facilitate the potential usefulness of PGHD.

Participants felt that the proposed objectives for PGHD were appropriate as a menu item rather than a core item. Moreover, they reported that data standardization across types and sources of PGHD was important both for integration of the data into the EHR and for research.

Conclusions: Overall, outpatient stakeholders had positive views about the proposed Stage 3 objective of the MU Workgroup of the Health IT Policy Committee for providers to receive PGHD; however, workflow considerations and EHR functionalities needed to support the receipt of PGHD are vital for the successful integration and use of this data.

Problem-Oriented Views Provide Cognitive Support to Decrease Drug Errors

Victoria Church, RN, MS, CNS-BC, Kathleen Adams, MPH
Portland VA Medical Center, Portland, OR

Problem Description

Optimizing health information systems is crucial to patient safety and the mission of the Portland Patient Safety Center of Inquiry (PSCI) and the Portland Informatics Center (PIC) at the Portland Veterans Administration Medical Center (PVAMC), a teaching hospital with complex disease processes, evidence-based protocols, and management strategies for a fragile geriatric population of patients. Many disease processes that were once managed by specialists are now expected to be managed by the general practitioner or internist. Additionally, clinicians must contend with fragmented information, functionally limited computer interfaces, and complicated medication distribution systems. The resulting cognitive burden associated with synthesizing volumes of information into problem identification, developing a treatment plan and assessing treatment response jeopardizes clinical outcomes.

Objectives

Reduce data fragmentation and enhance relevant data extraction from the electronic health record (EHR) for glycemic management, intravenous heparin infusion and medication reconciliation (MR) discrepancy detection.

Methods

We used discrete multi-modal assessments to create and evaluate the integrated displays. Three different inpatient user-centered analyses identified critical decision support needs. Non-participant observations provided qualitative data on prototype usability and usefulness. Clinical subject matter experts further refined the prototypes using an iterative design process incorporating user feedback. Chart reviews provided quantitative data on length of stay and errors detection.

Results

These tools improve provider efficiency and enable identification of optimal patient management strategies resulting in increased Return on Investment (ROI). Use of the glycemic control tool decreased the average Length of Stay (LOS) for patients from 11.2 days to 9.34 days. Using the 2008 ADA estimate of daily inpatient cost related to diabetes care ($1853), a reduction in LOS of 1.83 days resulted in a savings of $3391per patient. Heparin tool use resulted in 82% reduction in incorrect protocol selection and correct drip rate adjustment; ADEs decreased from 17 to 0 immediately following implementation. Use of the MR tool detected an average of 6.9 discrepancies per admission with 68% of those rated high/very high for severity. Using an avoidable adverse drug event (ADE) rate of 118/year and the average cost developed by Bond of $2378 per ADE, an estimated $280,604/year could be saved.

Conclusion

The informatics tools and processes **that replaced error prone, paper-based processes significantly decreased drug errors, improved operational efficiency,** and **staff performance.**

Understanding Primary Care Clinic Patients' Information Needs about their Clinic Visit

Martina A. Clarke, MS[1], Joi L. Moore, PhD[1,2], Linsey M. Steege, PhD[3], Richelle J. Koopman, MD, MS[4], Jeffery L. Belden, MD[4], Shannon M. Canfield, MS[5], Min Kim, PhD[1,6]
[1]Informatics Institute, University of Missouri, Columbia, MO; [2]School of Information Science and Learning Technology, University of Missouri, Columbia, MO; [3]University of Wisconsin-Madison School of Nursing, Madison, WI; [4]Department of Family and Community Medicine, University of Missouri, Columbia, MO; [5]School of Medicine Center for Health Policy, University of Missouri, Columbia, MO; [6]Department of Health Management and Informatics, University of Missouri, Columbia, MO

Abstract

To clearly understand patient information needs, promote informed clinical decision making, and quality patient care, 15 adult patients with acute illness and 14 adult patients with chronic disease were interviewed at a primary care clinic to identify what portions of the clinic visit note they viewed as important. Assessment and Plan were the most common note section identified as important by patients while Review of Systems was the note section identified least frequently as important.

Introduction

Better understanding of information needs is essential for providing patients with updated and relevant information for patient centered care. The purpose of this study was to identify patient information needs after a clinic visit with a primary care physician.

Methods

Two family medicine physicians (JLB and RJK) created fictitious but typical acute and chronic visit note. Sections in a visit note are: Chief Complaint, History of Present Illness, Past Medical History, Review of Systems, Physical Exam, Significant Lab Data, Assessment, and Plan. Fifteen patients with acute illness and 14 patients with chronic diseases participated in semi-structured interviews at the University of Missouri health clinics where patients were asked to identify important information they would need on a paper summary given to them after a visit with their primary physician. Data collection methods included a recorded interview containing 6 questions, Likert scales, Short Test of Functional Literacy in Adults and Patient Readiness to Engage in Health Information Technology survey. Thematic approach was used for qualitative analysis and differences in note section patient ratings of importance were evaluated by t-test.

Results

Table 1 Select examples of themes identified during data analysis and supporting quotes from interviewed patients.

Themes	Supporting quote
The Assessment (p=0.002) and Plan (p=0.045) were the most common note sections identified as important by acute and chronic patients when asked to choose three note sections to include in their end of visit summary.	"Well, again, because I would want to know for sure what the diagnosis was. I'd want to know what the update on it was, and I'd want to know what I need to do, the outcome of what I need to do because, that's the stuff I forget."
Review of Systems (p=0.003) was the note section identified the least by both patient groups when asked; patients viewed this section as unhelpful, stating that they already knew that information because it was about them.	"Cause I've already answered all those. I mean, it's just stuff I said. It's not his interpretation. There's not much to be confused unless he missed something, oh, he forgot to write down that my shoulder hurts, too."
67% of acute patients preferred online access to their information and 50% of chronic patients preferred paper access to their medical record (p=0.465). Acute patients wanted to be able to have access to their information at any time. One chronic patient had no interest in seeing their note.	"I guess just with the ease of the technology and basically that's it, less paper, less, just the ease of technology, basically that's all. It's something I don't necessarily want to leave laying around my house but if I have the availability to it, that would be nice."

Conclusion

This study demonstrates potential improvements to health information that patients receive after a clinic visit to support patient understanding of their plan of action. The results of patients' most commonly identified and least commonly identified note sections are also consistent with our other study findings identifying physician information needs. The results can be used to improve information that may be contained in patient health records (PHR) and patient portals. Further research is warranted to assess how to create accurate and reliable health information sources for patients.

Integrating Neighborhood Food Environment Data with a Comprehensive Community-based Survey Data to Support Population Health

Manuel C. Co Jr., MSN, MS, MPhil, RN[1], Suzanne Bakken, PhD, RN[1,2]
[1]School of Nursing, [2]Dept of Biomedical Informatics, Columbia University, New York, NY

Abstract

Geographic-level data can provide context to understanding the health of a community. This study reports our integrating neighborhood food environment data with our community survey data to enhance our understanding of the influence of place on health in a predominantly Hispanic low-income underserved urban population.

Introduction

Overweight and obesity affects lower-income communities of color living in areas with higher than average access to fast food restaurants and with limited access to healthy foods at reasonable cost such as those offered in supermarkets or other similar retail food outlets.[1,2] To gain a comprehensive understanding of those living in the Washington Heights and Inwood (WaHI) section of Northern Manhattan, this study was undertaken as part of the Washington Heights/Inwood Informatics Infrastructure for Comparative Effectiveness Research (WICER) Project to understand the influence of place on health in a predominantly Hispanic low-income underserved urban population.

Methods

The neighborhood food environment is characterized by integrating external geographic-level zip code data on food stores and farmers markets with geocoded WICER survey data on >5,000 WaHI residents. Food outlets were identified using the North American Industry Classification System (NAICS) definitions obtained from the ReferenceUSA national business database Major Industry Group codes and tabulated in Table 1. Data for the WaHI food environment is geocoded to transform street addresses into mappable data that can be spatially displayed and analyzed.

Result

Eight food outlet types were present in WaHI and total food outlets by zip code ranged from 46 to 79.

	Zip Codes					
NAICS Codes and Food Outlet Description	**10031**	**10032**	**10033**	**10034**	**10040**	**Total**
445110 Supermarkets and other grocery stores	45	64	53	34	42	238
445120 Convenience stores	2	2	3	3	2	12
445210 Meat markets	2	4	8		2	16
445220 Fish and seafood markets	1	2	4	1	2	10
445230 Fruit and vegetable markets		1	1	1	1	4
445291 Baked goods stores	2	2	4	1		9
445299 All other specialty food stores	1	1	1	2		5
447110 Gasoline stations with convenience stores		3	2	4		9
TOTAL	53	79	76	46	49	303

Conclusion

Integrating available external geographic-level data with our comprehensive community-based survey data provides context to our study of place and health of community residents with significant health disparities.

Electronic Health Record Systems (EHRS) Give Healthcare Providers a False Impression of Compliance with the Privacy and Security Meaningful Use Measure

Alex Cohn MSCIS[1], Andrea Bempong MBA[1], Kathy Fitzgibbon RN[1], Lanis L. Hicks PhD[2], Sam Ross, Theresa Walunas PhD[1], Adam Williams[1], Abel Kho MD MS[1]
[1]Northwestern University, Chicago, IL; [2]University of Missouri, Columbia, MO

Abstract

The HITECH act set up an incentive program for health care providers to implement and meaningfully use electronic health records systems (EHRS). In order to be eligible for incentive payments from the legislation, healthcare providers must meet a series of measures which include a privacy and security focused measure. This measure requires that providers conduct or review a security risk analysis of their organization. Some providers have the false impression that they are compliant with that measure even when no risk analysis has been done.

Introduction

In 2009 the American Reinvestment and Recovery Act included a section called the HITECH act. This legislation set up an incentive program for health care providers to implement and meaningfully use electronic health records systems (EHRS). In order to be eligible for incentive payments from the legislation the healthcare providers must meet a set of core measures and a set of their choice of menu measures. These measures are defined by the final rule for meaningful use released by the Department of Health and Human Services. One of the core measures focuses on privacy and security in health care practices and states the following objective:

"Conduct or review a security risk analysis in accordance with the requirements under 45 CFR 164.308(a)(1) and implement security updates as necessary and correct identified security deficiencies as part of its risk management process."

Meeting this objective is required for all healthcare providers who wish to receive incentive payments under this program. The formal process of conducting a security risk analysis and implementing a formal risk management framework presents a significant challenge to small health care practices and community health centers.

Study Design & Research Methods

The study was performed by distributing a link to an online survey that contained questions regarding EHRS adoption, and compliance with the privacy and security meaningful use measure. This link was emailed to healthcare providers who are members of the health information technology regional extension centers in the states of Illinois and Missouri and were believed to have achieved or were attempting to achieve meaningful use.

A portion of the data from the responses were analyzed to determine the understanding of the requirements for meeting the privacy and security meaningful use measure.

Results

We received 39 total responses (N=39). Of those respondents 37 had either attested that they had achieved meaningful use (MU) or that they planned to achieve MU. Of those 37 respondents 36 (97.3%) stated that they'd already met or planned to meet the privacy and security MU measure. Of those same 36 respondents 21 (58.3%) said that their EHR dashboard reported that they were compliant with the privacy and security meaningful use measure. When asked "What do you plan to do or have done to meet the security measure?" 7 (19.4%) of the previously mentioned 36 respondents indicated that their EHR told them they were checked and compliant with the security measure.

Conclusion

EHRS dashboards may be giving providers a false impression of compliance with the privacy and security meaningful use measure. The measure requires conducting a privacy and security risk analysis which is not recorded or entered into the EHRS. 20% of the respondents believed they were currently compliant based on the EHR dashboard. This survey represented a small sample of providers in two Midwestern states. A larger national study is necessary to confirm these results.

Clinical Informatics Program and Strategy to Support a Large-Scale EHR Implementation

Sarah Collins, RN, PhD[1,2,3], Saverio Maviglia, MD, MS[1,2,3], Perry L. Mar, PhD[1,2,3], Margarita Sordo, PhD[1,2,3], Li Zhou, MD, PhD[1,2,3], Charles Lagor MD, PhD[1], Roberto A. Rocha, MD, PhD[1,2,3]

[1]Clinical Informatics, Partners *e*Care, Partners HealthCare System, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA

Abstract

A well-organized Clinical Informatics (CI) program is essential for successful system implementations within large institutions. A defined CI strategy and approach can help ensure the institution's mission of providing high quality clinical care, conducting research, engaging in education, and serving the community.

Introduction

The implementation of an EHR system with advanced clinical features may require a cohesive CI strategy to realize improvement in quality and efficiency.[1] Partners *e*Care (P*e*C) is a large-scale effort to replace our existing systems with an integrated vendor-based solution. P*e*C includes a dedicated CI team responsible for all informatics-related activities and services. Current areas of focus include clinical decision support, knowledge management, interoperability (standards), and configuration management, and contributions to research and innovation (e.g., utilization monitoring, evaluation studies).

Methods

A cyclical framework that organizes CI services and activities was developed (Figure 1). The framework describes aims, roles, and deliverables from the CI program to P*e*C project teams. CI responsibilities (rounded boxes) and the responsibilities of implementation teams (text in brackets) are linked and mapped to typical project lifecycle stages.[2]

Results

We have been applying the CI framework with different projects (e.g., specification of decision support interventions, definition of shared data elements, mappings to standard terminologies) to facilitate and measure successful engagement. The framework helps explain roles and responsibilities of CI professionals, and also helps stakeholders understand how they can support CI professionals at different project stages.[3]

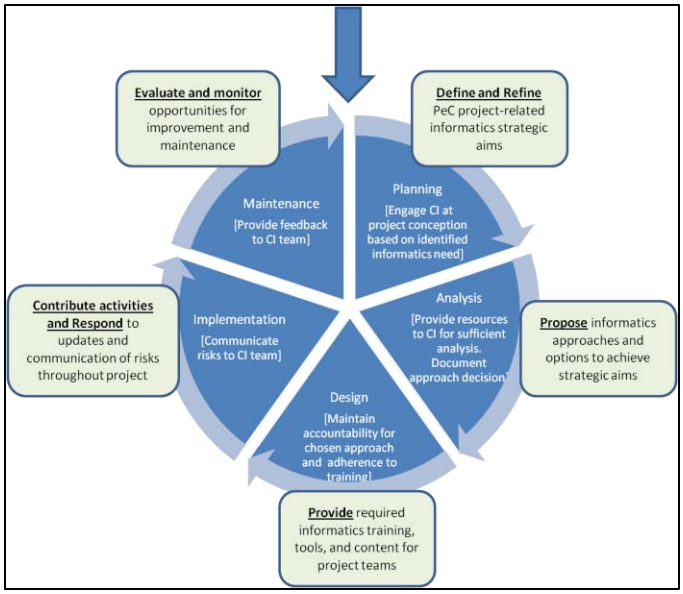

Figure 1 - Clinical Informatics (CI) framework defined for Partners *e*Care (P*e*C)

Conclusion

Ongoing P*e*C efforts underscore the importance of consistently providing CI expertise to help define and support EHR implementation activities. The proposed framework has established an effective mechanism for the CI team to support and collaborate with implementation efforts. Further work should evaluate its generalizabilty to other CI groups. The formal CI strategy promotes informatics best practices with proper utilization of resources, while ensuring that advanced EHR features are supported by evidence and acceptable to clinical users.

Rapid NLP Development with Leo

Ryan Cornia[1,2], Olga V. Patterson, PhD[1,2], Thomas Ginter[1,2], Scott L. DuVall, PhD[1,2]
[1]VA Salt Lake City Health Care System; [2]University of Utah, Salt Lake City, UT

Introduction
Structured data elements in a medical record poorly represent some aspects of a patient's state of health. Clinical text, on the other hand, can capture the specifics of complex and chronic conditions like the current stage of the disease, the rate of progression, and the ability of the patient to cope with and manage their condition. Natural language processing (NLP) unlocks the information in clinical text. NLP development kits, such as the Apache Unstructured Information Management Architecture (UIMA), provide common application programming interfaces (API) and data models that allow different developer groups to more easily collaborate.[1] UIMA Asynchronous Scaleout (UIMA AS) provides the ability to deploy NLP systems enabling scalable processing and can efficiently analyze large volumes of text. UIMA is a powerful and flexible framework, but in order to accommodate all the different functionality, configuration and deployment of systems built using UIMA, a set of XML descriptor files is required. Creating and maintaining these descriptor files manually can be complicated and time consuming. While UIMA components can be run within UIMA AS with no descriptor changes, additional descriptor files are required to deploy systems based on UIMA AS.
Despite the advantages of using UIMA, NLP system development continues to have a high entry barrier, requiring substantial setup, configuration, and framework specific knowledge. Projects like Apache uimaFit provides programmatic instantiation of UIMA components, but does not yet support UIMA AS deployment.
This poster introduces Leo, a Java-based framework built on UIMA AS that greatly reduces the barrier to entry by providing tools and base classes that facilitate rapid NLP system development and scalable deployment. Leo is named after the Spanish word meaning "I read".

System description
Leo was first developed to provide research teams in the Department of Veterans Affairs an accessible way to take advantage of the scalable processing provided by UIMA AS. The VA Informatics and Computing Infrastructure (VINCI) project led the extraction and aggregation of clinical text from VA medical records and now contains more than 2 billion clinical notes and reports. As many research teams did not have experience with enterprise software architectures, Leo provided libraries that would allow provide complex UIMA AS functionality with a simple API. Creating NLP pipelines, setting parameters, and defining annotation types are done programmatically, eliminating the maintenance required by UIMA descriptor files and allowing development to focus on honing NLP algorithms.

In addition to simplifying configuration and maintenance, Leo was further developed to include reusable, configurable components for finding keywords and phrases, using regular expressions and patterns, building complex rules for identifying and associating annotations within a document, mapping strings of text found in notes to standard terminologies, and developing feature vectors for training and validating machine learning components. Leo provides an extensive set of utilities for accessing documents and their associated annotations, reading and writing from various data sources, and performing annotation functions such as compare, find, and remove.

Leo supports the whole workflow of annotation, iterative NLP development, and validation by seamlessly connecting UIMA functionality with annotation and validation tools and machine learning libraries. The UIMA AS underpinning allows Leo to manage the scale needed for real-time processing and provides remote configuration tools for enabling automatic system optimization. It improves developer efficiency and simplifies NLP development. Leo has been extensively used on almost 100 projects processing millions of clinical notes.

The Texas Advanced Computing Center: A complete scientific discovery environment for biomedical informatics and health science research

Matthew C. Cowperthwaite, PhD[1], James D. Carson, PhD[1], John M. Fonner, PhD[1], Oscar D. Jiao, PhD[1], Jawon Song, PhD[1], Matthew L. Vaughn, PhD[1]
1. Texas Advanced Computing Center, The University of Texas at Austin, Austin, TX.

As the scale and diversity of biomedical data acquired in basic, translational and clinical research continues to grow, more powerful computing resources are needed to support the biomedical informatics community. The Texas Advanced Computing Center (TACC) is a leading academic computing center in the United States. We provide the medical informatics and computational biology communities with the most comprehensive scientific computing environment available, including more than 500,000 processing cores, over 100 petabytes of disk storage, dedicated large-scale visualization systems, and advanced networking and interface technologies. Using our systems, researchers can greatly increase the scale, speed, and throughput of their analyses, as well as conduct big-data studies that are impossible on standard workstation computers.

Life sciences computing at TACC is overseen by a dedicated group of scientists with expertise in genomics, molecular dynamics and docking, and image processing. The life-sciences group deploys and maintains more than 100 software packages of interest to the computational biology and informatics communities, including Matlab, R, Bioconductor, and FreeSurfer. TACC is a leader in the development of software tools for creating powerful, web-enabled scientific gateways such as iPlant and OpenfMRI; TACC also hosts and provide computing resources to the popular Galaxy informatics portal. Through these portal projects, we are able to offer advanced supercomputing technologies to more than 40,000 biologists and biomedical researchers.

TACC is also actively involved in training biomedical scientists to meaningfully incorporate computing technologies into their research programs. We offer roughly 40 courses and workshops via the NSF XSEDE program to more than 1000 researchers each year. As a result of these efforts, we have measured a fivefold increase in utilization of command-line interfaces to advanced computing technologies, to the point where they now comprise over 20% of our usage.

In summary, TACC provides a comprehensive computing environment to enable discoveries in the biomedical informatics space. Our resources are made available to the academic research community via the XSEDE program; industrial partners can work with TACC through our STAR industrial affiliates program.

Elders & Families Rely On Social Networks For Aging-Related Information: Implications For Informaticians

B.H. Crotty MD MPH[1], J. Walker RN[2], J. O'Brien BS[1], L Lipsitz MD[3], M Dierks MD[1], C. Safran MD MS[1]
Division of Clinical Informatics[1], Division of General Medicine & Primary Care[2] Division of Gerontology[3]
Beth Israel Deaconess Medical Center & Harvard Medical School, Boston, MA

Introduction

Aging creates new information and communication needs for elderly patients, as well as for their network of family members and caregivers. Recent data show that both elderly patients and their caregivers are turning to the Internet, but how seniors and families use technology to meet their aging-related information needs has not been fully explored.

Methods

We conducted a qualitative study of the information needs elders and families through a series of eight focus groups. Groups were comprised of either persons over the age of 75, or persons who care for a family member or friend over the age of 75. Groups lasted 90 minutes, and were organized around common experiences, such as managing chronic illness, recent acute care discharge, or assisted living. Groups were transcribed and reviewed using established qualitative methods, including immersion/crystallization.

Results

A total of 16 elderly participants (within 3 groups) and 22 family caregivers (within 5 groups) participated in the in the study. Participants characterized most needs as logistical including housing and transportation, access to basic health information, as well as communication with care providers.

We identified five core themes through our analysis, denoting that (1) seniors and families relied on their social networks for information gathering and appraisal, (2) information gathering requires active advocacy, (3) families often needed more information and communication during times of crisis, especially when occurring outside of business hours, (4) Internet users knew how to look for reputable information to trust, and most were wary of misinformation, and (5) tools and systems require sensitivity around issues of elder autonomy.

We found that seniors and families relied heavily on "word of mouth" and their social networks to find and appraise resources. Many participants supplemented their information gathering by Internet searches to validate what they heard through their social networks. Elderly participants frequently noted that "children do all the legwork," but many desired to be able to protect children from the burden of managing their medical conditions.

Discussion

Our findings are consistent with prior work that demonstrates the importance of social capital and social networks for health. In particular, seniors and families rely on others for information gathering and appraisal, using the Internet secondarily to supplement their research. Family members in particular expressed a desire to connect with one another for support. Participants desired tools to help fill current gaps, including times of 'crisis' or even 'routine' matters outside of business hours.

As the informatics community seeks to improve communication and information management for elderly patients and families, attention should be paid to social strategies and information tools to facilitate support for aging-related needs.

Abstract: *Clinical Decision Support systems (CDSS) can provide physicians with patient-specific recommendations, and suggest suitable treatment alternatives in case of drug-related risk. The objective of this study was to describe the overriding of alerts suggesting a medication substitution in patients aged 65 and older. A large proportion of these overrides occurred in patients aged less than 75 years and involved laxatives, psycholeptics and analgesics.*

Introduction: Several medications are not recommended for older patients.[1] The use of these inappropriate medications in older patients has been associated with adverse events, such as falls or delirium, and should be avoided. Clinical Decision Support systems (CDSS) can improve prescribing appropriateness in older inpatients (>=65years) by suggesting more suitable drugs. The objective of this study was to describe the overriding of substitution-suggesting alerts by prescribers in older inpatients.

Methods: The primary outcome measure was the count of age-related alert overrides over a period of three years (from Jan 2009 to Dec 2011) in a large academic medical center. Staff physicians, residents and non-physicians with prescribing authority were included. Demographic characteristics of patients were described. Drugs involved were categorized according to the Anatomical, Therapeutic and Chemical (ATC) classification system.

Results: A total of 33,141 overrides were observed during that period, equally distributed between 2009, 2010 and 2011. The overrides concerned 12,833 different patients (52% women). Average age was 74 at the time of override. A large proportion (57%) of these overrides occurs in patients less than 75 years old. Half of the alerts overridden concerned drugs used against constipation (bisacodyl rectal 45.0% and bisacodyl oral 5.2%). However, 26% of the overrides for rectal bisacodyl could possibly be considered as appropriate because these were single administrations. Other frequent overrides included psycholeptics (alprazolam 6.5%, diazepam 4.6%), analgesics (oxycodone 7.4%, meperidine 4.2%), psychoanaleptics (fluoxetine 4.0%, amitriptyline 2.1%), antiepileptics (clonazepam 6.2%) and anti-inflammatory drugs (2.6%). The top most frequent categories of drugs overridden did not differ when comparing patients aged less than 75 years old to those aged 75 and over (i.e. laxatives, psycholeptics and analgesics). However, the proportion of overrides of laxatives was higher in patients aged 75 and over (58.2% of all overrides in patients ≥75years vs. 46.8% in patients <75years, $p<0.001$), while psycholeptics and analgesics were detected in a lower proportion in these patients (13.9% vs 15.4%, $p<0.001$ and 9.7% vs. 13.4%, $p<0.001$, respectively).

Conclusion: The override of age-related alerts is an important problem. A large proportion of these overrides occurred in patients aged less than 75. Further work is needed to understand the reasons underlying these alert overrides, identify situations in which the override could be appropriate, and refine the alerts for optimized relevance.

What women want? Expressing women's voice on contraception

Kavitha Damal, PhD, CCRC, Division of Epidemiology, University of Utah & Salt Lake City Veterans Affairs Medical center, Salt Lake City, UT
Rebecca Morris, MPH, Department of Biomedical Informatics, University of Utah, Salt Lake City, UT
Qing Trietler-Zeng, PhD, Department of Biomedical Informatics, University of Utah & Salt Lake City Veterans Affairs Medical center, Salt Lake City, UT

Background
Women in the modern age have several different contraceptive options to choose from, with each method carrying its own list of risks and benefits. While contraception counseling/ contraception education materials are abundantly availably, they are highly biased towards clinical details. Female values such as peer-experiences, cultural attributes are seldom addressed, leaving behind a knowledge gap that confounds the ability of women to make optimal contraceptive choices. We purport that contraception campaigns will benefit from addressing the attributes that women are keenly interested in knowing about such that a vast majority of unintended pregnancies across the world can be effectively avoided.

Methods and Results
To better understand contraceptive information needs and information seeking through online social media, we gathered 453 messages (165 questions and 288 answers) from three contraception-related online forums (ehealthforum, netmums and ivillage). A majority of all posts (73.5%) referred to the forum users' personal experience, while 38.2% of the questions specifically enquired about others' personal experiences with contraceptives. A review of these forum posts suggests a strong interest among online users to seek and share personal experiences. The most commonly discussed birth control methods include birth control pills, IUD, implant, and the injection. A content analysis was performed on the messages and 10 salient topics emerged as tangible attributes that are of high interest to the forum users, suggesting that information that seems implicit to providers and contraception counselors are still not as clear to patients. Patients crave for information from peers on an interpersonal basis and contraception education needs to necessarily include these patient perspectives in a transparent manner in order to reap more successful outcomes.

In addition, we performed a top model analysis using an adapted Latent Dirichlet allocation (LDA) method. The topic model analysis generated 27 stable topics, i.e. topics that are consistent regardless in multiple runs.

Title: Piloting a network of CTS2 terminology service nodes for value sets

de Coronado, Sherri L[1], MS, MBA, Wright, Lawrence W W[1] MA, Fragoso, Gilberto[1], PhD, Stancl, Craig R[2], Solbrig, Harold R[2], MS, Bauer, Herbert[2], Endle, Cory[2], Peterson, Kevin J[2]
1.National Cancer Institute, Bethesda, MD. 2. Mayo Clinic, Rochester, MN.

The biomedical informatics community has moved substantially towards use of common terminologies for annotating and retrieving data, documents and samples. However, the numerous terminologies are developed with different frameworks and models, and they are distributed using a wide variety of formats and channels. Terminology services such as NCBO's BioPortal [1], NCI's Enterprise Vocabulary Services (EVS) [2], NLM's Unified Medical Language System (UMLS) [3], EBI's Ontology Lookup Service [4], and CISMeF's HeTOP [5], provide access to multiple terminologies in a single place; each has its own unifying framework and format, but with different application programming interfaces that impede interoperability between services.

Common Terminology Services Release 2 (CTS2) is a recent Object Management Group (OMG) and Health Level 7 (HL7) standard model and specification for discovering, accessing, distributing and updating terminological resources on the Internet [6, 7]. One potential benefit to wider adoption of CTS2 for terminology services is the inherent ability to create a network of terminology services nodes. There are advantages for both terminology services providers and users. Service providers may still need to provide many of their services to end users who have differing needs through their regular services, but a network of CTS2 nodes would reduce the need for multiple service providers to host terminologies of shared interest. There could be a canonical version of a particular terminology hosted at a particular node accessed by many sets of users. For users, one advantage would be ability to access more terminologies with the same set of service calls, irrespective of the provider. Secondly, they would be more certain that the representation of a given terminology/value set is consistent and is the one intended by the owner, even if the distribution format does not follow other guidelines (e.g. [8]). We report on a pilot project implementing a network of CTS2 terminology service nodes. This effort is starting with value sets, a high value commodity to the community, especially for those needing Meaningful Use value sets in combination with other value sets.

Approach: CTS2 enables the same queries to be used across different implementations of CTS2 nodes with different terminologies, mappings, and/or value sets. This pilot project explored the ease of operationalizing this network of nodes. Three CTS2 value set services were used to test the functionality: (1) The NCI LexEVS 6.1 implementation of value sets, which includes value sets used by FDA and CDISC; (2) The Mayo Clinic implementation of the NLM Value Set Authority value sets for Meaningful Use [9]; and (3) the Mayo TLAMP (Terminology Linux Apache MySQL) CTS2 service that packages several standard terminologies into a standards-based terminology service and exposes HL7 code systems and value sets [10]. Each CTS2 service was originally set up for a different purpose and set of users based on specific requirements. During the prototype phase we analyzed the common functionalities that are currently exposed by each service, and also identified modifications needed in either the way the terminologies and value sets are loaded or how the CTS2 services are implemented. The goal is to provide access across the test nodes to a core set of functionality for accessing specific value sets. We also report progress and lessons learned.

Automatic Content Extraction for Designing a French Clinical Corpus

Louise Deléger, PhD, Cyril Grouin, PhD, Aurélie Névéol, PhD
LIMSI – CNRS UPR 3251, Orsay, France

Abstract

To develop resources and tools facilitating Natural Language Processing for the clinical narrative in French, we plan to select a representative sample from a large corpus of French electronic health records (EHRs). To access the most medically relevant content of EHRs, we develop an automatic system to separate the core medical content from other document sections. The performance of automatic content extraction achieves 0.96 F-measure, on par with human inter-annotator agreement of 0.98.

Introduction

Clinical corpora are necessary to develop resources and tools facilitating Natural Language Processing for the clinical narrative. Our long-term objective is to build a corpus of French clinical notes annotated with entities and relations to enable medical NLP research in French. To this end, we plan to select a representative sample from a large corpus of French electronic health records (EHRs) and to base our selection on the most medically relevant content of the clinical notes. Indeed, clinical notes often include header and footer sections listing the names and contact information of doctors in a healthcare unit. These sections are sometimes lengthy and they are not as helpful to characterize the clinical content of notes as sections describing patient care. Herein, we present an automatic approach to separate the core medical content from other document sections such as headers and footers.

Methods

For this study, we used documents from a corpus of 138,000 clinical notes from a group of French healthcare institutions. To build our system, we established a typology of the sections occurring in clinical notes. We considered 4 high-level section types: (1) a *generic header*, containing contact information for the health care unit in which the note was created. This header is the same for all clinical notes from the same unit; (2) a *specific header*, containing specific information such as the patient's name, birthday, date of admission, etc.; (3) the *main content* of a note; and (4) a *footer*, consisting of the physician's signature, together with greetings if the document is a letter.
We manually annotated 2 samples of randomly selected notes, by marking the beginning of each section (3 annotators participated in the process). Inter-annotator agreement for identifying main content lines was 0.98. Sample 1 (200 notes) was used as a development corpus to design our system, and sample 2 (500 notes) as a test set to evaluate the final system. We trained a conditional random field (CRF) model to identify the sections and extract the main content of notes. We classified each line of a document as belonging to one section type, using the BIO (Beginning-Inside-Outside) format. Features included line length, the first and second tokens of a line, the presence of blank lines before a line, etc. This approach draws on previous work on section identification from clinical notes[1] (e.g., "Past Medical History", "Discharge Medication") and scientific abstracts[2] (e.g., "Background", "Methods").

Results and Conclusions

The accuracy of our system is 0.955. Detailed performance per section type is shown in Table 1. Content is identified with a very high recall (0.989). Performance is very good, so that corpus studies can rely on our method for extracting medical content from clinical notes.

Table 1. Performance of the system

Section type	*Precision*	*Recall*	*F-measure*
Generic header	0.986	0.962	0.974
Specific header	0.975	0.926	0.950
Main content	0.916	0.989	0.951
Footer	0.950	0.901	0.925

Data Transformation of Alzheimer's Data

Peehoo Dewan, BS, Naveen Ashish, PhD, Arthur W. Toga, PhD
University of Southern California, Los Angeles, CA

This poster describes a *data transformation engine* for "GAAIN" – the Global Alzheimer's Association Information Network where we are developing a pioneering integrated data access federation for data related to Alzheimer's research. The GAAIN effort is unique in being a first-of-a-kind initiative where Alzheimer's data can be accessed from multiple data networks around the globe in a seamless, integrated and secure manner. This work presents our work on the "GAAIN Data Transformer" – which addresses the specific aspect of transforming data from a GAAIN data *partner* to a common data model and standard developed by GAAIN. The overall GAAIN federation approach is based on a common data model, i.e., where data in each dataset from each data partner is *mapped* to a common data model for integration. The common data model is based on "CDISC" [2] elements and is under development.

For achieving this mapping in a scalable manner for each data partner, we have developed a GAAIN Data Transformer – which is a general-purpose software engine for transforming data partner data. Our paradigm assumes that a) Datasets (from data partners) will typically be available as "exports" in formats such as CSV, Excel or other, b) Data will be transformed to the GAAIN common data model, and c) The data transformer is configured declaratively through "transformation rules". The overall data transformation pipeline and the key modules are illustrated in Figure 1. The following are the key modules and their functionalities:

Database The transformer system includes an in-memory (relational) database, which is the staging database for the (original) data partner data (as is), as well as the cache for the data transformed to the GAAIN model.
(Data) Loader This module reads data from different export formats and loads it into the transformer database. We have written loaders for a variety of common export formats – for instance some data partners may provide all their data in one spreadsheet, others may organize as one (database) table per CSV file etc.,
Transformer Core (Mediator) The core of the transformer is an *Information Mediator* [1]. An information mediator is a general-purpose software system for integration of data from multiple heterogeneous data sources. Data from various sources is mapped to a common "global" model in the mediator. Data transformation is a special use case of the mediator where the mediator global model employed is the GAAIN common model, and the task of the mediator is to transform data from *one* source i.e., the data partner data into the global (GAAIN) data model. The transformation rules are based on *description logic* [1] and are expressive enough to capture *syntactic* as well as *semantic* data transformations.
Transformation Rules The mediator as transformer is powered by *declarative transformation rules* [1] which are logic-based rules that specify how exactly elements in the source data relate to the global GAAIN data model elements.

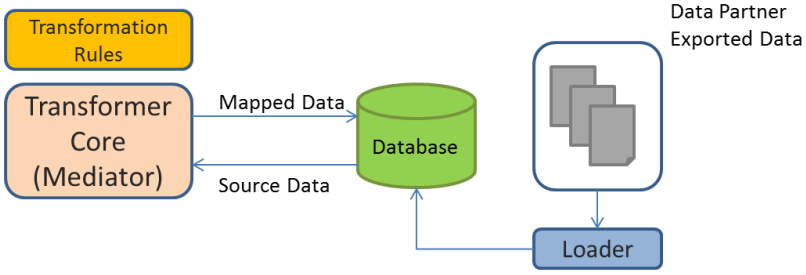

Figure 1. GAAIN Data Transformer

Currently we have developed a working first version of the transformer system and successfully employed it for data transformation from multiple disparate Alzheimer's partner datasets.

A Semantically Enhanced Clinical Rules Management Repository Prototype

Sahithya Dhamodharan, MS[1], Adela Grando, Ph.D[1], Davide Sottara, Ph.D[1]
[1]Department of Biomedical Informatics, Arizona State University, Scottsdale (AZ)

Abstract

We developed the prototype of a Clinical Decision Support (CDS) artifact management platform targeted to a variety of stakeholders, like physicians, knowledge engineers and quality inspectors. The system is built on top of a CDS artifacts repository, allowing the retrieval of artifacts by matching their content using semantic queries. The system partially automates their management by the use of appropriate meta-rules such as "If a clinical rule is in Draft status for more than 90 days, send a reminder to publisher". To this end, we encoded the CDS logic using the national standard Health eDecisions (HeD) format, which supports a variety of metadata annotations describing and summarizing the artifacts and their content. For a chosen subset of those attributes, we defined an ontologic model of their admissible values and types. This model provided the vocabulary and the concepts used by the queries and the rules. We implemented the prototype customizing an open source semantic content management system and tested it simulating different scenarios.

Introduction

Organizations like Partner's Healthcare, the Mayo Clinic and Intermountain Healthcare own dedicated repositories for rule-based CDS artifacts such as alerts. They are manipulated through knowledge management portals that allow users to retrieve the content based on a variety of search options. However, many portals only support basic SQL-like query capabilities. Recently, it has been shown that semantic - rather than purely syntactic - queries simplify the formulation of the search criteria and improve the accuracy of the results by "understanding" the intention and the contextual meaning of the search terms[1]. Semantic-based criteria would allow a variety of stakeholders with different roles to retrieve meaningful sets of rules in a precise and context-specific way. Queries, however, still require an explicit action from the user. In some cases, instead, it is desirable to define policies – and their relative actions - that would apply to CDS rules automatically as they are stored into the repository. To enable these use cases, we defined our tool to support semantic "meta-rules" in addition to semantic queries. For example, imagine a specialist such as a Pulmonologist, who may be interested in artifacts, related to his discipline and may want to be notified whenever a new active artifact is made available in the repository. He would use the portal and make a search for rules that apply to pulmonary diseases. Unlike syntactic queries, which can only filter exact values, semantic queries can traverse taxonomies and relationships. So, the semantic query makes use of the metadata model and retrieves artifacts whose clinical applicability is Asthma, Pertussis or any other type of pulmonary disease. Also, when a new artifact related to pulmonary disease is added to the repository, a meta-rule in the repository like "If an artifact applies to pulmonary diseases and its status is active then alert physician" gets triggered and a notification about the new artifact is sent to the physician.

Methods

First, a literature review to gather the state of the portals helped us identify the search criteria and the use case scenarios for potential stakeholders. Second, we identified a suitable format for the encoding of the CDS rules. We chose the HeD standard because it is based on XML; it is structured and facilitates the automated processing of its content. Moreover, it provides a schema that supports a variety of metadata that was derived from the harmonization of other clinical and non-clinical standards[2]. Third, we selected a subset of the metadata attributes (demographics, clinical focus, provenance and status) and we defined a semantic representation of their domains. For each one, we assembled a simple ontology based on medical and administrative concepts. The ontologies provided the vocabulary to write the queries and the meta-rules, as well as the models used by a semantic inference engine to execute them. Next, we developed a user interface to allow users to define and execute the queries and meta-rules. This interface allows selecting the search criteria using visual widgets such as lists and pop up menus. Finally, we created a prototype implementation as seen in Figure 1, based on standards and open source components. We tested the prototype on the set of rules distributed by HeD as reference examples. The set of rules from HeD in XML format was mapped to OWL as it is semantically more expressive that XML.

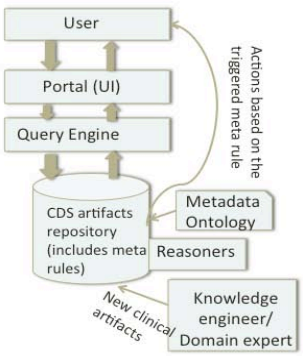

Figure 1: Clinical rules management repository prototype

Conclusion

Our preliminary results show that the use of semantic queries and rules can enhance the usability and usefulness of CDS knowledge repositories. Performance evaluation of the prototype with respect to precision and recall has to be done, once we expand and generalize our approach to include more attributes.

v3NLP Marshallers: Providing NLP Workflow Interoperability

Guy Divita[1,2], Brian Ivie[1,2], Qing T Zeng PhD[1,2],
[1]VA Salt Lake City Health Care System, UT; [2]University of Utah, Salt Lake City, UT

Abstract

Many commonly used NLP tools are used within medical community but the field has not yet standardized around one common interoperable plug and play messaging protocol/interlingua that satisfies all (sometimes conflicting) requirements. While interoperability efforts are underway, the necessity for systems to flow from one to another is being addressed within the v3NLP framework via marshallers that transform to and from other formats. V3NLP is a UIMA based framework. V3NLP's marshallers all transform into UIMA's CAS instances before being rendered out to other formats.The v3NLP marshallers are implemented as generic UIMA collection readers and collection writers and could be useful for stand-alone use to transform from one format to another, or within other UIMA based systems. The list below is by no means complete. There are marshallers that are waiting to be developed once there is an explicit need. The LAF/GrAF[1] ISO standard, now used for the American National Corpus Annotation effort, and a compact, terse marshaller that maximizes compression for efficient message transfer and file storage are next to be implanted. There are both general use GATE[2] to UIMA marshallers and some prior work done within v3NLP should a use case arise for such a need. The v3NLP marshallers are components of the v3NLP Framework, which is available via an Apache license and distributed from v3nlp.utah.edu.

Table 1: v3NLP marshallers

Marshaller	From	To	Comment
Text	X	N/A	No use case has come up to render back to text, yet.
UIMA XMI XML			This is UIMA's implementation.
Knowtator[3]/eHOST[4]	X	X	Knowtator and eHOST are useful full featured annotators.
CHIR Common Model	X	X	Used as an interlingua between v3NLP's lightweight Annotation viewer
CSV		X	There has not been a use case thus far to develop a marshaller to read from excel spreadsheets for further NLP processing, but it can be done.
BioC[5]	X	X	Distributed by NCBI.
Jdbc Database	X	X	Additional information about payload fields has to be provided.
Multi-Record Text Files	X	X	Useful to compactly bundle and read from a cohort corpus
VTT	X	X	VTT is a useful, lightweight portable Annotator distributed by NLM.

Assessing the Feasibility of Using Electronic Health Records for Community Health Assessments

Brian E. Dixon[a,b,c], P. Joseph Gibson[d], Karen Frederickson Comer[e], Marc Rosenman[b,f]

Abstract

Assessment is a core function of public health. Comprehensive clinical data may enhance community health assessment activities by providing up-to-date, representative information used in the development or application of public health programs and policies. Greater access to clinical data is possible with electronic health record (EHR) systems. Yet public health stakeholders often question the reliability, timeliness, and accuracy of EHR data. We developed a matrix to support assessment of EHR data quality across a range of common community health assessment indicators. The matrix was found to be useful and helped identify target indicators for a single assessment project. We hope the matrix can be used and improved by others to support greater use of EHR data for community health assessment activities within provider organizations as well as health departments.

Introduction

Community health assessments (CHAs) provide information for population health problem and asset identification as well as public health policy and program formulation, implementation, and evaluation. Comprehensive healthcare encounter data may enhance CHAs with up-to-date, representative information for improved development and application of effective public health programs and policies. Traditionally CHAs have been performed using a limited set of information available through public data sets, behavioral surveys, and paper-based disease reporting. Given greater availability of electronic health record (EHR) systems, public health departments might leverage new, electronic data sources to support community assessment processes.

Methods

Through a series of meetings, we iteratively designed a multidimensional matrix to assess the feasibility of using routinely collected EHR data captured by clinical organizations for CHAs. The matrix rates aspects of EHR data quality, such as reliability, timeliness, and accuracy, across a number of common CHA indicators, including disease prevalence, health outcomes measures, and health service performance measures. The matrix is designed to be used by a group of public health stakeholders when defining information needs for a specific use case as outlined in (1). We employed the matrix with and gathered feedback from a group of public health informatics researchers and stakeholders in a metropolitan area to define indicators for a project involving a health information exchange.

Results

Prevalence of chronic diseases as well as several "high-profile" quality and health service performance measures were believed to be feasible to incorporate into CHAs in a "Most Wired" area of the country. However, comprehensive assessment must include integration across currently fragmented clinical and public health data silos. For example, colorectal cancer screening data are available electronically, but only a few providers make these data available to the regional health information exchange restricting analysis to localized areas.

Conclusion

As health departments plan and implement electronic data feeds from clinical organizations, they should consider how to aggregate data across silos for more effective CHA. In addition, health departments should consider how other EHR data sources might be leveraged to improve health planning and policy activities. The matrix was useful in choosing CHA measures which local stakeholder perceived as available through EHRs.

Pain Assessment Screening Tool and Outcomes Registry (PASTOR)

Nhan Do MD[1], Kim Heermann-Do MHA[2], Rick Barnhill BS[3], Diane Flynn MD[3], Ivan Lesnik MD[6], Eric Shry MD[3], Mary Ann Rubinos MD[3], Terry Newton MD[1], Kevin Galloway RN[1], Karon Cook PhD[4], Richard Gershon PhD[4], Leslie Barker, RN[2]; Chester Buckenmaier MD[5]

Abstract

The Military Health System (MHS) is exploring the use of patient reported outcomes (PRO) with Computer Adaptive testing (CAT) to drive consistency in pain management practices. PASTOR was developed to facilitate the integration of PRO within the clinical workflow and information systems of the MHS's Interdisciplinary Pain Management Clinics and Patient Centered Medical Homes (PCMH). Work is in progress to develop study protocols with PASTOR for comparative effectiveness research and expand its use for other clinical domains.

Background

The estimated healthcare cost of chronic pain in 2010 exceeds the combined cost of cancer and diabetes by 30%. Failure to adequately address pain will continue to result in escalating healthcare costs as well as loss of productivity and income. An Army Pain Management Taskforce was chartered in 2009 to make recommendations for a comprehensive pain management strategy, and one of the Taskforce's recommendations was to adopt a clinical information system that provides pain assessment screening with an outcome registry to promote consistency in pain care delivery. Some challenges with implementation of PRO are a lack of information technology infrastructure, lack of guidance for providers on how to interpret and use the results, and lack of clear understanding of when and how often to use PRO in clinical practice. PASTOR is a system based on National Institute of Health (NIH) Patient Reported Outcome Management System (PROMIS) platform to deliver CAT through various information communication modalities and provide decision support for patients and clinical staffs.

System Description

PASTOR was developed at Madigan Army Medical Center in partnership with Northwestern University. Workflow analysis was performed in Madigan's Integrated Pain Management Clinic (IPMC) and PCMH during system design. The IPMC enrolls around 40 patients per week with an intake questionnaire and a baseline PROMIS pain domain instrument. After initial assessment, multiple treatment modalities are offered to the patient and treatment outcomes are monitored with the PROMIS instrument at least monthly or more frequently depending on the treatment modality. Once appropriateness for discharge from the IPMC to the patient's PCMH has been determined, the patients' results are made available for the primary care team through an electronic dashboard developed for the PCMH workflow. The dashboard assists the healthcare team in identifying risks, summarizes key information, follows trends over time, identifies polypharmacy, and evaluates effectiveness of interventions. Results of the PRO instruments are stored in the registry for reporting as well as in a document repository in the electronic health record.

Conclusion

Monitoring patient reported outcome is part of the MHS's strategy to reduce variability in pain management and propagate best practices. We have developed PASTOR to reduce the burden of tracking and maintaining PRO over time through computer adaptive testing and an electronic dashboard that provides decision support for interpreting and managing results within the workflow of both pain specialty care and primary care clinics.

Gathering Information for Situation Models of Syndrome Identification

Kristina Doing-Harris PhD, Charlene Weir PhD
VA Health Care, Salt Lake City UT
University of Utah, Biomedical Informatics Department, Salt Lake City UT

Abstract: *Automatic identification of syndromic illness in EHRs could provide a substantial contribution to clinical decision support systems. Evidence for syndromes is most consistently documented in the narrative notes. Thus, its extraction will require natural language understanding. Cognitive Psychologists recognize that understanding language depends on situation models. The work in this poster begins the process of situation model development by reviewing charts to find descriptions of delirium. Even in a small sample of charts, situational descriptions are complex, overlap mainly on a point of omission, and indicate that a formal diagnosis is associated with worry. These situational findings are associated with the text's author leading us to conclude there are two relevant situational models, one for the text's subject and one for its author. We find that the author's model should include inferences about reasons for noting and coding, ideas of completeness and differential diagnoses.*

Introduction: Syndromic illnesses are some of the most difficult illnesses to diagnose because, by definition, they do not have definitive diagnostic tests. Therefore they are likely to benefit the most from clinical decision support (CDS). However, these CDS systems must be able to identify cases.

Delirium is an example of a syndrome that is difficult to diagnose based on chart review because it is often recorded in narrative notes, but rarely in ICD9-CM codes (paper presented here). This pattern may be due to the complicated patient situation associated with Delirium. While it is easy to recognize when a patient is delirious, the patient may only be given a diagnosis if the care team is worried their care being affected.

Therefore, the construction of a system to automatically identify syndromic illnesses will require natural language understanding. Cognitive Psychologists have recognized since 1983 that text based models of language comprehension are inadequate. The consensus is that situation models are combined with text-based representations.[1] Situation models are thought to consist of instantiated schemas, where different schemas apply to different aspects of the current situation. Schemas are prototypical instances of canonical situational aspects. The classic example is eating at a restaurant. A restaurant schema would include the activities "waiting for a table," "being seated," roles "waiter," "chef," and objects "cutlery," "napkin." Schemas allow the integration of world knowledge (in the form of expectations) with information from the current situation. In order to identify the scope of the Situation models and schemas for Delirium, we have undertaken a chart review to find the situations in which a patient is diagnosed with Delirium.

Table 1. Evidence of Delirium from three patient records.
Admitting diagnosis: altered mental status; Cognitive: Impaired vision, impaired hearing LOC: Calm, Confused Oriented to (person/place/time/situation): Person
…presents with altered mental status and report of several recent GLF's. Cognition: Patient is oriented to self only. He states that the month is July and could not offer days of the week, date or year. He shows inattention with inability to spell WORLD backward. DSM-IV DIAGNOSIS: Axis I: 1. Delirium 2/2 multiple etiologies 2. Dementia NOS (likely mixed)…
Admitted for altered mental status, failure to thrive in a setting of UTI. GENERAL – alert, oriented to person and time, NAD A gradual progress in what seems to be a chronic dementia Failure to thrive, gradually progressive weakness, confusion

Methods: The first author examined patient data, with IRB and DART approval, in the VINCI workspace. The patients were selected from the SLC VA population: over 65, inpatient stay in the last year on the acute medicine or telemetry wards. In this study 30 patients' notes for a single stay were read. 8 patients' notes were examined in detail to identify the diagnostic situation.

Results: Table 1 shows the evidence of delirium from three patient records. While both patients one and three were admitted for altered mental status, only patient two had an ICD9_CM code for Delirium, ground level falls (GLFs) and a Psychiatry referral with full work up. Both patients two and three have also been diagnosed with dementia. All three notes mention altered mental status and patient orientation, notable by the omissions of two or more aspects. The only patient with a formal diagnosis had an associated fall risk.

Conclusion: In reading the notes it became apparent that there were two situation models at work. In order to build a model of the patient's situation, it was necessary to construct a model of the note author's situation. Most importantly the note author's model must address the discrepancy between narrative descriptions and ICD9_CM codes. In the example notes, we postulated that the worry over fall risk motivated the formal diagnosis. Secondarily, it must address the author's notion of completeness in order to detect deliberate (as opposed to accidental) omissions. In addition, it should include the author's conception of the distinction (or not) between delirium and dementia.

Individualizing Information Presented in Quality Dashboards: Preliminary Study

Dawn W. Dowding, PhD, RN[1,2], Yolanda Barrón, MS[2], Sylvia Ames, BA[2]
[1]Columbia University, New York, NY; [2]Visiting Nursing Service of New York, New York, NY

Abstract

Information regarding quality measures are often presented to staff in the form of dashboards using visualization techniques. The Visiting Nursing Service of New York (VNSNY) has over 150 such dashboards/interactive reports that can be accessed by administrative and clinical staff. This preliminary study explored the pattern of use of the dashboards over 1 year by users across VNSNY. The data will be used to develop strategies for individualizing the information provided in dashboards to users.

Introduction

Dashboards integrate and visually display information (often focusing on quality measures) to inform decisions about the delivery of patient care. [1] The Visiting Nursing Service of New York (VNSNY) currently provides over 150 customized dashboards/interactive reports (visualized displays of data) for administrative and clinical staff on a variety of quality and outcome measures. The purpose of this study was to explore patterns of dashboard use, with the aim of developing dashboards individualized to user information needs.

Methodology

Log files which list the individual user, which dashboard they accessed and date of access were obtained from the period 1st December 2012-30th November 2013. Data were analyzed to provide descriptive statistics. Heat maps (constructed in Microsoft Excel) were used to explore patterns in dashboard use.

Results

Over the 12 month period 1206 unique users accessed the dashboards, with a total of 30,029 hits. The role of the user and the department where they worked influenced the dashboards that were accessed most frequently (Figures 1 and 2). Users working in a clinical role were more likely to access the information contained in 'quality scorecards', which provide data on a variety of quality outcomes related to processes and outcomes of care. In contrast users with an administrative role were more likely to access information related to a patient's risk of rehospitalization.

Figures 1 and 2: Heat map patterns of Dashboard Use by Role of the User and Department

Conclusions

Our analysis indicates that there is considerable variation in the information accessed by individuals depending on their role in the organization and/or the department where they work. There are some dashboards (e.g. the Quality Scorecard) that have utility for individuals across roles and departments, and others which are only useful for some users or areas of the organization. We will be using this information to develop strategies for individualizing the information provided in dashboards, to the needs of users. We will also be exploring how to present this information to users at the time and location of their decision making.

Using Laboratory Data for Prediction of 30-Day Hospital Readmission of Pediatric Seizure Patients

Amie J. Draper, BS[1], Ye Ye, MS[1], Victor M. Ruiz, BS[1], Christina Patterson, MD[2], Andrew Urbach, MD[2], Fereshteh Palmer, RN[2], Shouqiang Wang[2], Mark Somboonna[2], Fuchiang Tsui, PhD[1]
[1]Real-time Outbreak and Disease Surveillance Laboratory, Department of Biomedical Informatics, University of Pittsburgh, Pittsburgh, PA
[2]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA

Abstract: *Laboratory data may provide valuable clinical information related to a patient's risk of readmission. This study assessed the contribution of laboratory data in predicting readmission risk for pediatric seizure patients. We extracted basic summary features from laboratory data and selectively incorporated them into a baseline prediction model to determine if readmission prediction accuracy could be improved. We found that the added features from laboratory data increased the model's AUROC from 0.55 to 0.63 with borderline significance (p-value=0.023).*

Introduction: Hospitals have been challenged to reduce pediatric readmission rates by 20% (recently estimated at 6.5%)[1]. Pediatric seizure is the fourth highest contributor to readmission risk[1]. To the best of our knowledge, prior studies have not identified readmission risk factors specific to pediatric seizure and have incorporated little to no laboratory data, which may provide information about a patient's condition[1-3]. We hypothesize that identification of patients at risk of readmission can be improved by utilizing laboratory test results. This study focuses specifically on pediatric seizure patients, but our hypothesis can be further tested on patients with other diseases.

Methods: We retrieved all in-patient electronic health records (EHRs) for visits to the Children's Hospital of Pittsburgh of UPMC during 2007-2012. Of these visits, 3,286 were seizure-specific based on discharge ICD-9 codes and 2,417 had laboratory test values for eight different test types (e.g. sodium). Abnormal/normal tests were identified according to age-specified normal ranges. We extracted basic features to summarize laboratory data for each patient, which included the percent of abnormal tests, the most recent test value, and the test type weight (Number of tests for a given test type/Number of all tests). The data were split into training (2007-2011; 234 readmissions, 1733 controls) and testing (2012; 75 readmissions, 375 controls) sets. A Naïve Bayes classifier using only patient age as a feature was our baseline prediction model. We used information gain ratio with 10-fold cross validation to rank each feature in the training dataset. Features were added individually in order of average merit to the baseline model and were kept if the accuracy of the model improved when using 10-fold cross validation on the training data. The final model was retrained and the testing data was used to compute the area under the receiver operating characteristic curves (AUROCs) of the baseline model and the new model, which were then compared.

Results: We found three laboratory features that improved the prediction accuracy of the baseline model: 1) percentage of abnormal blood nitrogen urea (BUN) tests, 2) the most recent potassium (K) test value, and 3) the most recent chloride (Cl) test value. The AUROCs of the baseline model and the model with the added features were 0.55 and 0.63, respectively (p-value=0.023).

Discussion and Conclusion: Clinically, derangement of homeostasis can potentially cause seizure[4]. The three automatically selected laboratory test types (K, Cl, BUN) reflect homeostatic conditions. The accuracy of a readmission predictive model for pediatric seizure patients increased when incorporating information from laboratory data, which implies that laboratory data may be useful to healthcare providers identifying patients with risk of being readmitted. Future work will include adding more clinical information for readmission risk assessment and examining additional patient populations.

Title: Data for Patient-Centered Outcomes Research on Care Processes, Transitions, and Coordination

Theme: Clinical Research Informatics

Authors: Prashila Dullabh, Lauren Hovey, Michael Latterner, Samantha Zenlea, Petry Ubri

Introduction and Research Objective

There is a growing effort by clinical care settings, public health organizations, and researchers to share information in a way that enhances clinical decision-making and patient care in real time and contributes to a learning health care system.[1] This paper addresses important challenges and opportunities to patient-centered outcomes research (PCOR) on care coordination and transitions. Specifically, we focus on the data infrastructure necessary to support this research, including: 1) Actions needed to identify, share, and harmonize data across sources; 2) Essential data infrastructure at the individual and population health levels (e.g., data standards, security); and 3) Existing linkages, data sources, and services that could be leveraged.

Methods

This qualitative study included; 1) an environmental scan and literature review to identify key resources; 2) Semi-structured telephone interviews with 13 experts on data and research on care transitions and coordination; and 3) An in-person advisory work group to discuss a strategic roadmap for resolving data-related issues.

Principal Findings

Essential needs and areas for improvement include: standard measures to capture care coordination activities; strengthening the use of common data elements and standards, filling gaps in existing standards; mechanisms to collect, share, and incorporate patient-generated health information into PCOR; information exchange and interoperability among researchers, clinicians, and care coordinators; linking relevant data sources; and developing mechanisms that support quality improvement activities.

Conclusions

Here, we present a summary of essential needs, improvements, and mechanisms to support PCOR on care coordination and transitions, as well as opportunities for short term, strategic investments that alleviate common challenges and advance the field. In spite of their different vantage points, experts converged on a number of important opportunities to bolster data sharing, infrastructure, policies, and other accelerants of PCOR in this area. We also identify use cases for data on care transitions and coordination that would greatly benefit both clinical providers and researchers conducting downstream research to improve patient outcomes.

[1] The Learning Healthcare System, as conceived by the Institute of Medicine, refers to a vision of the healthcare system in which "science, informatics, incentives, and culture are aligned for continuous improvement and innovation, with best practices seamlessly embedded in the delivery process and new knowledge captured as an integral by-product of the delivery experience."

Check it with Chex: A Validation Tool for Iterative NLP Development

Scott L. DuVall, PhD[1,2], Ryan C. Cornia[1,2], Tyler B. Forbush, RCP, Corinne H. Halls, MS[1,2], Olga V. Patterson, PhD[1,2]
[1]VA Salt Lake City Health Care System; [2]University of Utah, Salt Lake City, UT

Introduction

Natural language processing (NLP) system development typically follows an iterative software development life cycle. Rapid error analysis and performance evaluation are essential steps in timely and successful system implementation. In many cases, an annotated dataset to support system development may not exist, or may be small due to cost and other factors, yet the developer must evaluate in order to iterate. This common scenario often results in highly skilled team members performing tasks that lie outside their skillset. Developers often take on the role of clinical experts in the iteration cycle because it has been challenging to display system output and collect feedback from clinical professionals in a system that is easy to set up and use. Likewise, clinical professionals struggle to provide feedback and clinical perspective in a format that can be easily implemented in the system design.

While multiple tools exist for chart abstraction (such as Knowtator or eHOST), none of these tools are optimized for system output review. To meet the need to support a rapid annotation, we developed a system, called Chex, that provides an easy, user-friendly way to validate system output for accuracy.

Chex was designed to enable developers to easily output system annotations to a database, and clinical reviewers and research team members to easily set up the desired workflow and rapidly validate the system output. Multiple human reviewers can validate on a project, if assigned by the administrator, allowing scale-out of reviewers to meet the needs of the developer and project. Each reviewer is provided annotations to validate as they complete them, eliminating the time needed for batching and managing reviewers' pace and workload. The results of the validation are written back to the database in a format that is directly consumable by the system developer or machine learning components, all resulting in much faster evaluation, and subsequent iteration cycles.

System description

Chex is a web-based application that can be configured for instance level or classification and extraction NLP system output. NLP system annotations and any associated features are displayed in a user-defined context window from the document. In cases where more context is needed, a single click will pop up the full document text with the annotation information. The interface can be customized by the administrator. In order to simplify management of annotations tasks, Chex is integrated with Business Process Management 2.0 for defining validation workflows, and utilizes a common database schema for reading and writing annotations. Chex uses the open source product Activiti (http://activiti.org/) for its workflow implementation, allowing for flexibility in how processes are defined and used, and following existing process definition standards. Chex is database platform independent, and can draw text and annotation data from most major databases.

Chex has two levels of access – administrator and user. Administrators have the ability to create new validation projects, create user accounts, assign specific users to annotation projects, and review summary reports. User level access is given to clinical specialists that serve as human reviewers. Annotation project definition includes the following elements: database connection information, annotation schema definition, a list of assigned reviewers, and annotation instructions for the chart reviewers. Once a validation project is created and users are assigned, each user has the ability to specify the number of annotations to draw for review and enter validation decision for each presented validation annotations. Each reviewer can be assigned to multiple validation projects at the same time, and each validation project can have multiple assigned reviewers.

Once NLP system output is reviewed and validated for accuracy, Chex summary reporting functionality can be used to review annotations at a project level or drill down to an individual annotation level.

Conclusion

NLP system development greatly benefits from an intermediary error checking. By supporting manual chart validation, Chex improves the iterative development process by providing timely error analysis, thus improving the quality of an NLP system.

Informational Needs During Intensive Care Unit Physician Handovers: A Multicenter Survey

Lewis Eisen, MD[1], Irene Yip[1], Pierre Kory, MD, MPA[2], Brian Gross, M.Sc., BSEE, RRT, SMIEEE [3], Brian Pickering, MD[4], Vitaly Herasevich, MD, PhD[4], Michelle Gong, MD[1]

1 - Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY, 2 - Beth Israel Medical Center, Mount Sinai School of Medicine, NY, NY, 3- Philips Healthcare, Andover, MA, 4 - Mayo Clinic, Rochester, MN

Problem: The Joint Commission has identified communication errors during patient handovers as a potential source of patient harm. According to the Joint Commission handovers should 1) Identify relevant people related to patient care, 2) Provide clinical information, 3) Communicate issues specific to the patient, 4) Present expected trajectory, problems and solutions and 5) Assign accountability for monitoring and checking on the patient.
Current status: No electronic medical record (EMR) tool exists that cover all aspects of Joint Commission suggestions for adequate handovers even though clinical data relevant to handovers may be found in EMRs. In the data heavy environment of the intensive care unit (ICU), it is not clear what information intensivists think is important to communicate directly during handovers in the ICU and what data can be abstracted from the EMR.
Potential solution: AWARE (Ambient Warning And Response Evaluation) is an EMR vendor independent and real-time electronic dashboard for extracting and presenting high value clinical information at the bedside which could be modified to present important information for handovers [1].
Objective: To understand information needs during handover process in the ICU.
Results: A survey was administered to a convenience sample of 103 attending intensivists in 4 United States academic medical centers. The ICUs at all participating sites have electronic medical records(EMR) and one site already uses AWARE in the ICUs. Overall response rate was 41%. Most respondents hold primary board certification in internal medicine (66%) or anesthesia (32%). Respondents predominantly worked in medical (41%), surgical (17%), cardiothoracic (17%), burn (3%) or mixed medical and surgical (22%) ICUs. Most respondents work in large ICUs: 15% work in ICUS with >25 beds, 27% with 21-25 beds, 30% with 16-20 beds, and 28% with 10-15 beds. 94% had night intensivists. The respondents reported spending a median of 5.5 minutes signing out each patient after each shift and a median of 6.3 minutes signing out each patient at the end of a week.
The following handover survey items were deemed important by greater than 90% of respondents and are readily available in most EMR: Patient name, source of infection, additional organ dysfunction, chief complaint, mental status, hemodynamic status, code status, risk of deterioration, operation type, pertinent intraoperative issues, pending tasks, pending consultations, prioritization of pending tasks, opportunity for questions.
The following survey items were deemed important by greater than 90% of respondents and are not currently available in most EMR: poor patient response to specific therapies, variances from standard patient presentation, anticipated problems, recommended solutions to problems, contingency planning. The one site where AWARE is available in the ICUs was significantly more likely to identify items as not important to communicate in handovers as the information is already easily available to the clinician in the EMR and AWARE (median 8.5 interquartile range 3-14 vs. median 1 interquartile range 0-2) $p<0.001$)
Conclusions: This survey has identified several handover items deemed important by an overwhelming majority of intensivists. ICUs that currently use AWARE are more likely to state that information commonly included in handover is already easily accessible to the clinician. Using these survey results, a handover tool with AWARE has potential to be adapted to fulfill all Joint Commission suggestions and items deemed important by intensivists in our survey.

Pilot Assessment of a Caregiver Decision Support Mobile Health (mHealth) Application for Food Allergy and Anaphylaxis in the School Environment

Christina Eldredge MD MS[1], Golam Mushih Tanimul Ahsan[2], Asriani Chiu MD[1], Brenda White Ed.S.[3], Taylor Atchison BS[1], Leslie Patterson PhD MS[1], Sheikh Iqbal Ahamed PhD[2]
[1]Medical College of Wisconsin, Milwaukee, WI; [2]Marquette University, Milwaukee, WI; [3]Archdiocese of Milwaukee Office for Schools, Milwaukee, WI

Abstract: *Food allergy is an increasing common student health condition in the school environment which requires prompt use of an epinephrine auto-injector in the event of accidental exposure. A mobile health (mHealth) caregiver decision support application for electronic food allergy action plans was piloted with teachers in the school environment using case-based scenarios. Initial teacher assessment of this application revealed the need for more student specific caregiver instructions and more emphasis on epinephrine auto-injector instructions.*

Learning Objective 1: Understand the need for caregiver decision support applications to help manage children with potentially life-threatening food allergy.
Learning Objective 2: Understand the importance of usability testing in mHealth application development.

Background: Food allergy is a chronic health condition and frequent cause of anaphylaxis (a severe potentially life-threatening allergic reaction) in children.[1] The prevalence of food allergy is rising among school-aged children with approximately 1-2 children in each class living with this condition.[2] Caregiver recognition of anaphylactic symptoms and immediate treatment with an epinephrine auto-injector is critical for child survival during an anaphylaxis episode as these incidents often occur in community settings (e.g. schools). National guidelines recommend the use of paper emergency action plans. However, many schools do not have on-site nurse support and students have frequent caregiver transitions (e.g. field trips, aftercare) which can lead to potential points of failure in school emergency health response. Therefore, there is a need for electronic exchange of student-centered food allergy action plans with interactive caregiver decision support, specific for use in the school environment.
Methods: An interactive electronic food allergy emergency action plan (eEAP) was developed by a multidisciplinary team for an iPad, iPhone, or Android device. eEAPs entered by school healthcare providers can be viewed by school staff securely at remote sites. The eEAP decision tree is based on evidence-based medicine and nationally accepted food allergy emergency action plans. Five teachers were recruited for pilot assessment of the system's accuracy and usability using two case scenarios developed in collaboration with an Allergist. The user's interaction was observed by two study members and documented via voice recordings. After testing, two post-survey tests were completed, one by the user and another by an observer.
Results: Four teachers participated in study as of July 2014. Teachers rated the app high on a 1-5 scale in both ease of use (4.74/5) and willingness to adopt the app at school (4.25/5). Three out of four participants did not correctly complete the first case scenario, all due to errors in epinephrine administration. However, all participants correctly made the decision whether to inject epinephrine. The second case scenario was completed successfully by all participants. Several usability and design issues were identified including the need for more "personalized" student eEAPs, improved student search mechanisms to decrease time to access of the eEAP, and improvement of the epinephrine auto-injector instruction screens.
Conclusion:
Initial usability assessment of this application revealed the teachers' need for more student specific caregiver instructions and more emphasis on epinephrine auto-injector instructions. System redesign is addressing these issues and lessons learned based on user input will be presented in November.

The Need for a Nimble Decision Support Tool for Implementing Clinical Pathways in Oncology

Aymen Elfiky, MD, MPH(1,2); Adam Wright, PhD(2); Julie Bryar, MPH(1); Joseph Jacobson, MD (1); David Bates, MD, MSc (2); Edwin Rodgers (3); Kathleen Lokay(3); David Jackman, MD(1)
(1) Dana-Farber Cancer Institute, Boston, MA; (2)Brigham and Women's Hospital, Boston, MA; (3) D3 Oncology Solutions, LP, Pittsburgh, PA.

Problem Addressed:

Given the drive toward value-based health care, clinical pathways (CPs) are being used to plan, deliver, and review care. As an evidence-based clinical decision support (CDS) tool, CPs nonetheless require tailored implementation to reflect nuanced organizational infrastructure and care preferences. Concurrently, as a quality improvement tool, CPs help define anticipated care decisions and outcomes. As such, CPs content is continuously re-evaluated in light of evolving clinical evidence and practice metrics.

Within the context of a rapidly evolving oncology landscape, the challenges to implementing CPs within a tertiary cancer center include keeping pace with changing clinical content, quantifying levels of evidence, integration of a clinical trial portfolio, maximizing utilization of provider CDS to minimize unwarranted variability, and analyzing variability to identify improvement opportunities.

Purpose of System:

The Via Oncology Pathways portal is a nimble software platform that actualizes consensus-based, multidisciplinary clinical content at point of care through an interactive decision making tool. In parallel to provision of CDS, it also plays an important role in clinical practice improvement. Specifically, the portal is being piloted initially within the Genitourinary and Thoracic Oncology disease centers as part of a cancer care reform strategy at Dana-Farber Cancer Institute to coordinate an agile and iterative process of:

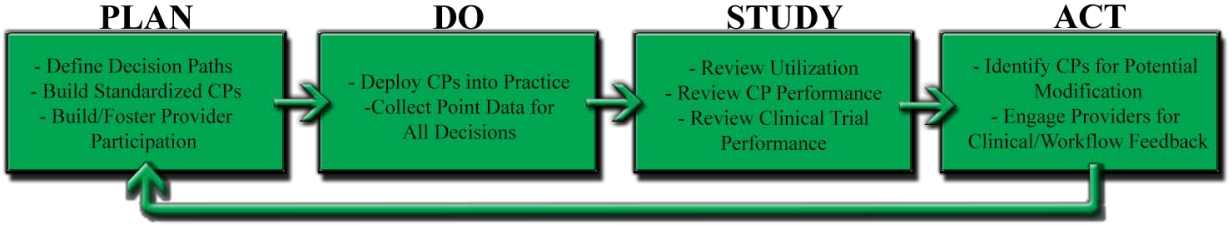
(i) clinical content development:
- defining distinct decision paths – branching, evidence and evaluation criteria within branches
- quantifying levels of evidence
- building discreet, standardized CPs into an algorithm
- incorporation of local preferences including clinical trials

(ii) delivery of algorithm in a user interface:
- deploy an XML-based "Disease Version" reflecting above local preferences
- employ a runtime environment to display and capture clinical info discreetly
- interface with practice management system to present patients respective to the provider
- consistently collect all point data for "on-" and "off-pathway" decisions

(iii) assessment of platform use:
- review utilization/login by providers
- review CPs performance in capturing "on-" and "off-pathway" rates
- review of clinical trial performance i.e. presentation of active portfolio, number of patients enrolled in trials, number of screening failures

(iv) process of Via platform modification:
- identification of specific CPs for potential modification based on "on-"/"off-pathways" rates
- continued engagement providers in workflow feedback and CPs updates

The above process can be conceptualized within context of a quality improvement framework as follows:



Future Directions:

These data provide the foundation for other analytics which allow for total quality management and improving both clinical and research programs. Via Pathways platform performance and feasibility will help dictate decision by the cancer center to scale the platform's use in the other disease centers.

eHealth Strategy transforming health care delivery in Tanzania

Mturi Elias[1], Jovitus Mukela[2], Hermes Rulagirwa[2], Prof Andrew Swai[2], Happy Danford[2], Sri Perera[3], Niamh Darcy[1] • [1]RTI International, NC, USA; [2]MOHSW, Dar Es Salaam, Tanzania; [3]CDC, Dar Es Salaam, Tanzania

Tanzania national eHealth Strategy 2013-2018

1. Background

- There is increased interest by national and local governments, partners, and private institutions to invest in global and national eHealth initiatives..
- eHealth can transform health care delivery by enabling information access and supporting health care operations, management and decision-making. The successful implementation of eHealth requires strategies that are aligned with the national respective health priorities.
- There are several models or frameworks for developing a national eHealth strategy, often developed by technologists and thus are complex to understand and use by health system actors; Often there is a missing causal link between health sector priorities and how technology can be applied to these priorities

2. Objectives

- Develop a pragmatic eHealth strategy framework that is guided by health sector priorities and also easy to implement
- Demonstrate feasibility by applying this framework to develop the national Tanzania eHealth Strategy 2013-2018

3. Methods

- Review existing strategy and eHealth strategy methodologies. This includes the
  - WHO eHealth Strategy Toolkit[1], Business Motivation Model[2] and Ishikawa Fishbone Diagram Strategy development model
- Review existing national eHealth Strategies including Canada[3], Australia[4]
- Complete a practical application of this eHealth strategy framework in Tanzania over 12 months (Sep 2012 to Sep 2013)
- Final launch of the Tanzanian eHealth Strategy 2013-2018 on 30 September, 2013 and national eHealth Steering Committee inaugurated on the same date

4. Results

- The eHealth Strategy was guided by the Tanzania Health Sector Strategic Plan (HSSP) III (2009-2015), which identifies health sector priorities.
- The initial background work occurred over a period of 2 years, culminating in a 1 week multi stakeholder workshop (health sector and ICT/eHealth experts) in September 2012 that used this framework to develop the eHealth Strategy
- Continued Ministry of Health and Social Welfare (MOHSW) and stakeholder review resulted in a final eHealth Strategy publication in September 2013.
- The following figures illustrate the 1) eHealth Strategy Development Framework, 2) mapping of the HSSP III (2009-2015) health sector priorities to the eHealth Strategic Objectives and 3) the four eHealth Pillars and their related Strategic Objectives

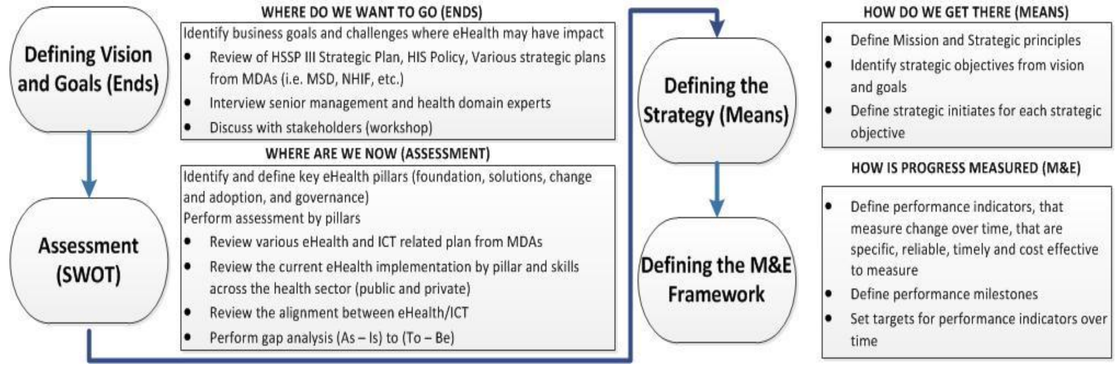


Figure 1: eHealth Strategy Development Framework

Health Sector (HSSP III) Strategies	eHealth Strategic Objectives																	
	SO1	SO2	SO3	SO4	SO5	SO6	SO7	SO8	SO9	SO10	SO11	SO12	SO13	SO14	SO15	SO16	SO17	SO18
District Health services	√			√					√	√	√							
Referral Hospital Services				√					√	√								
Central-Level Support																		
Human					√						√							

Figure 2: Linking eHealth Strategic Objectives to Health Sector (HSSP III) Strategies

Foundations	Solutions
SO1. Enhance ICT infrastructure and services to improve communication and information sharing across the health systems and at all levels	SO4. Enable electronic financial management to ensure effective collection, allocation, and use of health financial resources at all levels in accordance with health plan priorities
Change and Adoption	SO5. Strengthen an electronic HR system to improve planning and management of health professionals at all levels
SO15. Establish a comprehensive change and adoption strategy to promote and enforce the development and use of eHealth solutions for both public and private institutions at all levels	SO6. Enable an electronic logistics and supplies system to ensure adequate quality and quantities of health commodities are always available at the point of service to meet patient demand
Governance	SO7. Enable electronic delivery and interventions of health services to reduce child mortality ; maternal mortality ; and the burden of HIV/AIDS, TB, malaria, and non-Communicable diseases
SO16. Establish an eHealth governance structure and mechanism to ensure effective management and	SO8. Strengthen an electronic health management information system (HMIS) to support evidence-based health care and decision making

Figure 3: eHealth Strategy Pillars and Strategic Objectives

5. Summary

The Tanzania eHealth Strategy 2013 – 2018 was launched on 30 September, 2013.

The national eHealth Steering Committee was inaugurated on 30 September, 2013 and has met several times.

6. eHealth Strategy Vision & Mission

Vision: By 2018, eHealth will enable a safe, high-quality, equitable, efficient and sustainable health system for all citizens by using ICT to enhance planning, managing, and delivering health services.

Mission: To support the transformation of the Tanzanian healthcare system by leveraging ICT to improve the health and social welfare of all citizens.

7. Limitations

Known limitations of the eHealth Strategy framework

- This framework has only been applied in Tanzania
- The eHealth Strategy implementation is under way but is not yet complete

Point-of-Care Knowledge-Based Resource Needs of Clinicians: A Survey from a Large Academic Medical Center

MA. Ellsworth, MD[1], JM. Homan, MA[1], J. Cimino, MD[2.3], SG. Peters, MD[1], BW. Pickering, MD[1], V. Herasevich, MD, PhD[1]

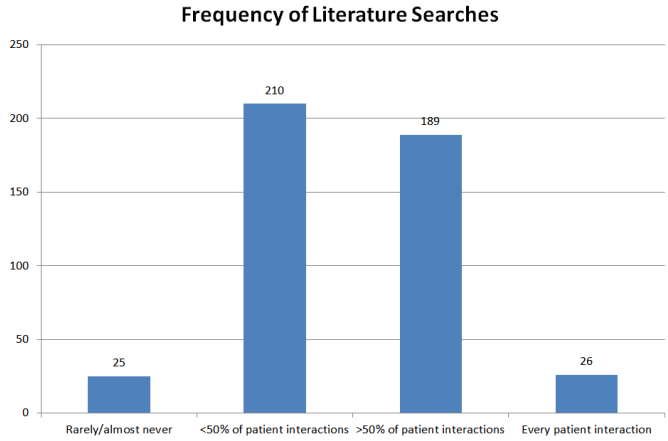
1 - Mayo Clinic, Rochester, MN, 2- Laboratory for Informatics Development, NIH Clinical Center, Bethesda, MD, 3 - Department of Biomedical Informatics, Columbia University, New York, NY

Abstract: *A single center survey demonstrated that medical providers frequently perform literature searches to answer clinical questions related to recent patient interactions. There is a distinct preference for using synthesized information sources mainly for the diagnosis and therapy domains. Adapting point-of-care information tools to match the preferences of the users potentially increases their usage rates and overcomes barriers often cited for not performing knowledge searches.*

Introduction: The development of point-of-care context-sensitive information retrieval tools, termed infobuttons, link local clinical information systems to electronic knowledge resources to aid in clinically related knowledge searches. Adapting infobuttons to the clinician's needs are necessary to provide resources that are tailored to their specific preferences in an effort to increase the sensitivity of their use and limit information overload. We conducted a survey at our institution to better understand the literature searching tendencies of clinical providers in order to best create adaptive infobuttons suited to their needs.

Methods: A survey regarding literature searching preferences was sent to 1862 unique clinical providers throughout the Mayo Clinic. The survey consisted of 25 items asking respondents to select which clinical scenarios most often prompt literature searches as well as identify their most preferred knowledge resources. Demographic data regarding the respondent's clinical role and area of patient care were also included. The clinical role or practice area for individuals offered an invitation to respond could not be determined (it could only be determined in returned surveys) limiting the ability to determine response rate by role.

Results: A total of 450 completed surveys were returned and analyzed (24% response rate). The number of respondents varied according to clinical role and patient care area (outpatient – 40%, OR – 24%, hospital floor – 21%). 48% of respondents perform literature searches for more than half of their patient interactions with 91% of all searches occurring either before or within 3 hours of the patient interaction. When a search is performed 57% of respondents prefer synthesized (i.e. UpToDate) information sources as compared to only 13% who prefer original research (i.e. PubMed). The two most common clinical domains that prompt literature searches are therapy (80%) and diagnosis (46%) with only 13% of respondents frequently searching for prevention related clinical answers. UpToDate was the most selected preferred reference in all 4 clinical domains with 68% of respondents selecting this reference in both the therapy and diagnosis domains. The 2 next most popular sources for therapy questions were MEDLINE and Micromedex with Google and MEDLINE following for diagnosis related questions. Additionally, more than 30% would ask a colleague and/or reference AskMayoExpert when faced with a therapy or diagnosis question. 82% of knowledge searches are performed on a workstation or office computer with just 10% occurring on a mobile device or at home. Finally, the number one identified barrier to an effective literature search was lack of time.



Discussion: Providers in our survey demonstrate a large need to answer clinical questions on a regular basis, especially in the diagnosis and therapy domains. Most of these searches occur in the patient care setting within a very short time from the patient interaction using synthesized (i.e. UpToDate) knowledge sources. Reasons for these preferences could not be gleaned from this survey design. However, these findings underscore the need for the creation of point-of-care tools that can guide clinicians to clinical answers quickly and efficiently. Adapting infobuttons that include only sources for specific domains that are preferred by the user would best accomplish this and provide an environment where quick literature searching is accomplished while at the same time avoiding the complication of information overload.

Development of an Efficient, General Purpose TCP/IP Listener in Perl to Capture HL7 Data for Real-Time Clinical Decision Support

Richard H. Epstein, MD, CPHIMS;[1] Michael Perino, BS;[2] Jerry Magrann, MS[2]
[1]Jefferson Medical College and [2]Thomas Jefferson University Hospital, Philadelphia, PA

Abstract
We developed a general purpose Perl script to receive HL7 data from an interface engine (via a TCP/IP socket) and store it in a relational database. Our method bypasses limitations of EHR databases optimized for transactional throughput rather than query performance, thus making the data accessible for real-time clinical decision support. At least 1295 transactions per minute can be processed with perfect accuracy.

Introduction
To implement automated clinical decision support (CDS), algorithms require real-time access to electronic health record (EHR) data, much of which originates outside the EHR and is transmitted using the HL7 standard. Interface engines are deployed to receive such data and populate the EHR database. However, these databases are often designed primarily for transactional throughput, rather than for query performance, a CDS requirement. Additionally, important HL7 data are frequently transmitted but not stored in the EHR database. The purpose of this project was to develop an efficient, general purpose method using open source tools to capture HL7 data and to store that information in a relational database, making it available for CDS. We assumed that organizations would already have an HL7 compatible interface engine. The use case was a need for real-time monitoring of transactions in the perioperative period involving controlled substances ("narcotics") executed by anesthesia providers on a distributed network of approximately 50 Pyxis® (CareFusion) automated drug delivery cabinets (ADDCs).

Methods
The open source language Perl (www.perl.org) was used to develop a short "listener" script to which our interface engine (Cloverleaf®, Infor) connected over a persistent TCP/IP socket. The open source IDE platform Padre (www.padre.perlide.org) was used for software development and testing on a network server hosting a Windows 7 virtual machine (VM). The CPAN library *dbi* (search.cpan.org) was used to enable database connections. The dbi:ODBC:driver = {SQL Server Native Client 10.0} was loaded *via* the complimentary installation of SQL Server Express 2008 R2 (Microsoft) on the VM.

HL7 vending transactions are filtered by the interface engine according to the physical location of the ADCC and scheduled drug class of the transaction. Fields from the MSH, PID, FT1, and ZPM segments (as identified in the Pyxis HL7 reference manual) are concatenated into a pipe delimited string for each transaction using Tool control language (Tcl), embedded in the Cloverleaf Interface, and then sent to the perl listener using the TCP/IP socket. Data are received to a buffer by the listener, logged locally to a text file on the VM (for debugging), and written to a SQL 2008 R2 database, located on a separate server. An acknowledgment (ACK) is sent back to the interface engine and the socket address and port refreshed, resulting in transmission and processing of the next transaction message in the queue.

Performance metrics were obtained using a custom perl script on the VM that simulated performance of the interface engine. Processing times were logged for 100 groups of 100 transaction messages, each transmitted immediately after each ACK was received. The mean processing time ± standard error were determined using the method of batch means for the N=100 groups. Accuracy was assessed by comparing the transmitted messages to the values populated in the SQL database.

Results
Processing time was 46.3 ± 0.44 msec per transaction. This permits a throughput of at least 1295 transactions per minute. Of the 10,000 messages transmitted during the test, 100% were inserted correctly into the database.

Conclusions
The developed system met our criteria of efficiency, accuracy, and use of open source software. For our use case, the highest frequency of transactions over a 2 month interval in any given minute was 11. Thus, our process has a capacity at least 100x greater than anticipated peak demand on a relatively low performance Windows 7 VM. Our process can be applied to any HL7 transactions that can be concatenated into a single, delimited string. Perl's strong support of text parsing and readily available libraries for construction of TCP/IP sockets and database connectors make this language an excellent choice for such use.

Process Improvements from Implementing an Electronic Checklist and Rounds Choreography to the Intensive Care Unit

Aysen Erdogan MD, Sumanjit Kaur MD, Lisbeth Y. Garcia Arguello MD, Hart L, John C. O'Horo MD, Ronaldo A. Sevilla Berrios MD, Adil Ahmed MBBS, Vitaly Herasevich MD, PhD, Brian Pickering MBBCH, Ognjen Gajic MD

Multidisciplinary Epidemiology and Translational Research in Intensive Care (METRIC), Mayo Clinic, Rochester, MN

INTRODUCTION: The volume of data generated in the intensive care unit (ICU) environment provides ample opportunity for errors, both from commission and omission. We have developed an electronic, context-sensitive rounding tool that algorithmically selects which relevant best practice goals to be addressed for each patient on a daily basis. This was integrated into a novel electronic platform, the Ambient Warning and Response Evaluation (AWARE) system. It prescribed a rounding choreography termed ProcessAWARE. In this preliminary study we sought to test the adoption and effectiveness of this intervention on the processes of care in the ICU.

METHODS: In a tertiary medical center medical ICU, 50 random patient-days were selected from April 2013 for appraisal of adherence to each of 16 best practice items included in the rounding tool that were reliably assessable. This was compared to 50 random patient-days from April 2011, the last year in which no checklist component of AWARE was available. Best practice adherence in the two time frames was compared.

RESULTS: Cases and controls were similar in respect of demographic characteristics. APACHE III scores at 1 hour were higher in 2013 (46 vs 64, p <0.01). Changes in processes outcomes presented in table.

Table. Process outcomes on April 2011 (Pre-AWARE) and April 2013 (Post AWARE implementation)

Variable	Pre-AWARE	AWARE with Checklist	P value
Sedation break	5/10 (50%)	19/21 (90%)	0.02*
Address Delirium	3/25 (12%)	2/25 (8%)	1.00
Addressed Pain	5/12 (42%)	2/7 (29%)	0.65
Review necessity of vasoactive medications	9/9(100%)	12/15 (80%)	0.27
Review cardiac medications	27/29 (93%)	23/24 (95%)	1.00
Appropriate use of stress ulcer prophylaxis	38/50 (76%)	40/50 (80%)	0.23
Review necessity of antibiotics	41/42 (98%)	44/47 (94%)	0.62
Address Infectious Source Control	5/20 (25%)	0/20 (0%)	0.05*
DVT prophylaxis appropriate	45/50 (90%)	48/50 (96%)	0.43
Central line necessity reviewed	11/22 (50%)	14/24 (58%)	0.77
Fluid balance goal established	29/50 (58%)	34/50 (68%)	0.41
Electrolyte Review	35/50 (70%)	38/50 (76%)	0.65
Urinary catheter necessity reviewed	16/29 (55%)	18/40 (45%)	0.47
Glucose reviewed	23/50 (46%)	19/50 (38%)	0.54
Physical Therapy goals reviewed	5/50 (10%)	12/50 (24%)	0.10
Goals of Care addressed?	37/50 (74%)	46/50 (92%)	0.03*

CONCLUSIONS: The initial implementation of a context-sensitive electronic rounding tool was associated with improvement in addressing goals of care and sedation practice. Clinician training and further refinement on the automated algorithmic function are needed to improve the adoption of the structured rounding tool.

De-duplicating Distributed Research Cohorts using Health Information Exchange Identity Services

Jon-David Ethington, MHS, PA-C[1,2], Shan He, PhD[1], Jerry M. Westberg[1,2], Darren K. Mann[1], Sidney N. Thornton, PhD[1,2],

[1]Intermountain Healthcare, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT

Abstract

Health Information Exchange (HIE) identification services can be repurposed to de-duplicate distributed research cohorts. An investigator can increase the statistical power of a research question by extending cohorts across organizational boundaries. The clever reuse of HIE identification services may reduce an organization's participation risk in inter-organizational studies by systematically preventing inadvertent disclosure of Personally Identifiable Information (PII), and avoiding the need for a pre-correlated, static master subject index.

Background

Distributed analytics may benefit from enhanced healthcare data interoperability. By using existing query tools, a research question can be applied to both internal and external cohorts, thus providing an investigator with increased statistical power[1]. De-duplication of the distributed cohort, however, is required. A constraint of de-duplication processes is that either PII must be disclosed for the purpose of resolving duplicates, or the researcher must subscribe to a federated service typically relying on static, pre-correlated repositories of identifiers. Since healthcare data interoperability also relies on patient identification across organizations, it is reasonable to adapt HIE identification services for research purposes. Such a strategy provides on-the-fly cohort identification without the need to maintain a costly, pre-correlated, static master subject index across organizations. Furthermore, HIE identification services such as developed by the Care Connectivity Consortium (CCC) provide dynamically-generated, non-PHI disclosing correlations back to the participating organization[2].

Approach

The existing patient identity management of the CCC forms the basis for the cohort de-duplication service. Demographic information for patients from distributed sources identified by the cohort query tools are sent to the CCC identification service's batch matching interface. The CCC matching engine links patient records that are considered belonging to the same entity through querying an existing identity correlation table built from previous operational transactions, its built-in probabilistic matching algorithm, and external authoritative sources such as commercial identity services or state department of transportation databases. For any unresolved identifiers, a level of certainty is calculated. For each study question, the service provides a list of de-duplicated, study-specific identifiers, and the linked organizations to each identifier without disclosing the organization-specific PII.

Results

This service provides to the investigator a de-identified, coded list of potential subjects, and the organization of origin for those subjects. For both resolved and unresolved identities, a level of certainty is supplied. The service also provides a throughput for data collection by communication with the utilized query tool without storing data.

Conclusion

It is possible to apply HIE identification services to research purposes and reduce organizational risk in participating in inter-organizational studies by systematically preventing inadvertent disclosure of PII. The service can be used with existing query tools without the need for additional master subject indices across member organizations.

Virtual Learning Environment: a Proposal for Teaching Emergency Care for Nursing Students through WebQuest

Yolanda Dora M. Évora, RN, PhD[1], Marta Cristiane A. Pereira, RN, PhD[1], Andrea Bernardes, RN, PhD[1], Carmen Silvia Gabriel, RN, PhD[1]
[1]University of São Paulo College of Nursing, Ribeirão Preto, São Paulo, Brazil.

Abstract

The aim of this study was to develop a virtual learning environment (VLE) for teaching emergency care for nursing students, using tools of Information and Communication Technology. The design, based on Computer-Mediated Education learning, have the constructivist approach. The WebQuest methodology presents the following components: Introduction, Task, Process, Evaluation, Conclusion and Credits. It was available in Moodle platform, enabling safe use of the internet to find information.

Introduction

Due to the increased number of cardiovascular incidents, traffic accidents, violence and insufficient structuring of the health care network, the need to intensify educational activities in these scenarios arises such a strategy to qualify the patient care.
The aim of this study was to develop a virtual learning environment (VLE) for teaching emergency care for nursing students, using tools of Information and Communication Technology.

Method

This is a methodological development research involving the creation of a Virtual Learning Environment by using the WebQuest as a teaching methodology and pedagogical strategy. The design, based on Distance Education learning Computer-Mediated, have the constructivist approach. The WebQuest was developed in Power Point (Microsoft ®) following the structure: Introduction, Task, Process, Evaluation, Conclusion and Credits. It is available in Moodle platform, providing for the students, links that allow access to the internet pages or websites.

Results

The VLE involved with the development of the WebQuest presents the following components[(1)]: Introduction: short text that introduces the subject and anticipates which activities the students should conduct. Task: Describes what is expected of students in the end and what tools they should use for their training. Process: steps that students have to follow for developing the task. Conclusion: summarizes the issues explored in the WebQuest, the goals achieved and supposedly indicates how the student can continue to study the issue. Evaluation: Rubric evaluation for use in self-assessment, peer assessment and teacher assessment. Credits: Present the sources of all materials used by the teacher in the preparation and development of the WebQuest (hypertext, photos and educational videos).This WebQuest is simple, objective and easy to use, and its potential is extensive, allowing the nursing student to have a dynamic learning, access to large amounts of information, perception of information, construction and application of knowledge, and activity involving research, reading, collaboration and interaction.

Conclusion

The use of WebQuest strategy as a virtual learning environment applied to the teaching of emergency care is a viable and innovative possibility. The teacher becomes a facilitator and helps students to construct knowledge. This research presented a pedagogical proposal that seeks to integrate theory and practice, from the appreciation of the knowledge and context of real situations experienced in daily life, based on resources of the computer and information technology. Continuing the study seems relevant evaluating the effectiveness of virtual learning environment for the students of undergraduate courses in the health areas. This challenge demands more work and also the evaluation by experts in Emergency care.

iDECIDE: A Mobile Application for Pre-Meal Insulin Dosing Using an Evidence Based Equation to Account for Patient Preferences

Akram Farhadi, MS[1], Buffy Lloyd, B.S[1], Danielle Groat, B.S.[1], Jelena Mirkovic, Ph.D. [2], Curtiss B. Cook, MD[3] , Adela Grando, Ph.D.[1]

[1]Arizona State University Department of Biomedical Informatics, Arizona;

[2]Oslo University Hospital HF, Oslo, Norway; [3] Mayo Clinic, Division of Endocrinology, Arizona

Abstract

Type 1 diabetes (T1D) requires the patient to conduct frequent self-monitoring of blood glucose and dosing of insulin. Evidence has shown that patients are more compliant with their diabetes management when they incorporate personal preferences[1]. We have developed a mobile application prototype, iDECIDE, to further personalize pre-meal insulin dosing by incorporating current evidence related to two variables that influence prandial glucose level: alcohol and exercise.

Introduction

Insulin pumps are medical devices that deliver continuous insulin. Current insulin pumps do not incorporate the latest medical evidence to further personalize *pre-meal insulin dosing* based on individual's *preferences* for *exercise* and *alcohol* intake[2, 3]. Evidence shows that these personal preferences have a short-term impact on *glucose measurements*, which in turn affects insulin dosing. The proposed solution is to incorporate these parameters into the current equation that calculate and *recommend insulin dosing* to help achieve *target glucose*. In contrast, there are numerous mobile applications for diabetes management that allow users to track carbohydrate intake, exercise, medications and insulin dosage. iDECIDE differs from these current mobile applications in that it is evidence based, a criteria largely missing in current mobile applications**.**

Methods

First, we conducted a literature review to gather the latest guidelines and evidence on insulin dosing for T1D patients to expand the current insulin dosing equation to include exercise and alcohol intake. Second, we created three prototypical T1D patient case scenarios with different pre-meal preferences. The scenarios were based on the American Diabetes Association guidelines and the opinion of domain experts. Third, we use the Ontology Web Language (OWL) to model the domain knowledge (Fig. 1 depicts main OWL classes and relationships).

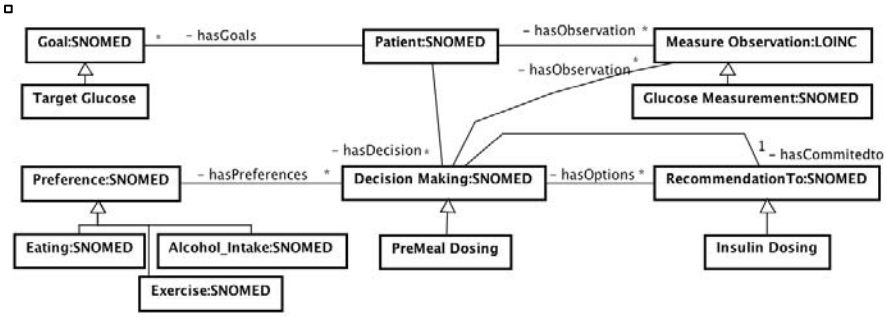

Figure 1: Knowledge Representation

Finally, we deployed a mobile application prototype (Fig. 2) that uses the new dosing equation to suggest insulin amounts based on patient's glucose reading and pre-meal preferences for carbs, alcohol and exercise.

Figure 2: iDECIDE Mobile Application

Future work

We have submitted an IRB for approval to conduct a preliminary retrospective calibration of iDECIDE evidence-based formula. We will collect data from 20 diabetes patients on alcohol and exercise preferences, and data generated from their insulin pumps. We will compare insulin recommendations from iDECIDE against insulin pumps, as recorded by study participants. Future work will also incorporate patient SMART goals (Specific, Measurable, Attainable, Realistic and Timely) related to fitness and nutrition to further help patients achieve a healthy lifestyle.

Exploring the Use of SemRep Predications to Help Identify Secondary Drug Targets for Personalized Cancer Therapy

Safa Fathiamini, MD[1], Amber Johnson, PhD[2], Vijaykumar Holla, PhD[2], Ann Bailey PhD[2], Jia Zeng, PhD[2] , Lauren Brusco, PhD[2], Funda Meric-Bernstam, MD[2], Elmer V. Bernstam, MD[1], Trevor Cohen, MBChB, PhD[1]

[1]The University of Texas School of Biomedical Informatics at Houston, TX

[2]The University of Texas MD Anderson Cancer Center, Houston, TX

Abstract

We report some preliminary findings related to our efforts to utilize SemRep predications as a means to identify associations between molecular aberrations and targeted cancer therapies in the literature. Though SemRep by design emphasizes precision over recall, we found extracted predications to be an informative source of gene-gene relationships. Utilizing newer versions of the UMLS improved the ability of SemRep to recognize agents of interest.

Introduction

Genetic information used in personalized cancer therapy is complex, drug responses vary from patient to patient, and no updated comprehensive resource describing these variations exists. Therefore, researchers manually catalog recent discoveries published in journals to support clinical decisions. Notably, therapies can be targeted to the patient's specific molecular aberration, or to a secondary (downstream) target. Our goal was to automatically identify drugs that target specific genetic alterations through a *secondary target downstream of the altered gene*.

Methods

We used a gold standard developed by a panel of experts at the MD Anderson Cancer Center Sheikh Khalifa Bin Zayed Al Nahyan Institute for Personalized Cancer Therapy (IPCT). The gold standard consisted of one main gene (GeneA), two intermediate genes/proteins (GeneB) that interact with the main genes and 7 drugs (DrugA) that inhibit GeneB or GeneA. In search for relationships, we used this pattern: "DrugA inhibits/interact_with GeneB" (Pattern1). We used SemMedDB[1] to identify those Medline abstracts (28,839 abstracts, Set1) that contained any mention of GeneA or GeneB. SemMedDB is a predication database provided by SemRep team which by default uses MetaMap/UMLS 2006 as its backbone, and contains more than 70 million predications extracted from more than 20 million citations. To find Pattern1 relationships with the most recent versions of UMLS/MetaMap, we modified the UMLS 2013AB data files and used them to create an up to date version of MetaMap, and used them as the backbone for our locally run SemRep (SemRepLocal). We then ran SemRep2 on Set1 to create a database with 2,346,486 predications.

Results

With respect to identification of genes, we were able to identify matches for 100% of the gold standard GeneA and GeneB concept exemplars in SemMedDB. Using Pattern1 to identify DrugA, the precision and recall were 0.3% and 29% with SemMedDB, and 1% and 100% with SemRepLocal, respectively.

Conclusions

When newer versions of MetaMap/UMLS are used, SemRep is able to identify more cancer related drugs. The still low precision with SemRepLocal may be due to the fact that our gold standard only includes those drugs that are clinically available and relevant, while our system retrieves all concepts with pharmaceutically-related UMLS semantic types. Further review of the results in order to identify sub-categories of drugs and exclude the ones that are of no known clinical benefit may lead to the development of methods to improve precision, such as the application of more sophisticated filters. Though further evaluation is required before definitive judgment can be made about the practical value of such search methods, a clear finding of our current efforts is that the modified UMLS 2013 data files we have employed are required for recognition of many key cancer-related drugs. This is a prerequisite to the application of SemRep to the task of identifying pertinent indirect targets for personalized cancer therapy.

Effect of Informatics Intervention on Compliance with Surgical Quality Metric

Vitali Fedosov, MD, PhD[1]; Ing C. Tiong[1]; Brian W. Pickering, MD[1]; Vitaly Herasevich, MD, PhD[1]
Multidisciplinary Epidemiology and Translational Research in Intensive Care (METRIC),
Mayo Clinic, Rochester, MN, USA

Abstract: Carefully built and appropriately implemented automated notification system of health care providers on the essential clinical parameters can improve the quality of care and impact reimbursement[1]. We have developed the automatic notification panel on the glucose level in critically ill patients presented in an intensive care unit (ICU) within 18-24 hours post an anesthesia time (SCIP-4 metric). We utilized the existing Ambient Warning And Response Evaluation (AWARE) middleware database tracking patients from the operating room and surgical ICU. The trial implementation of the developed tool was conducted by two nurses. The pilot study testing automatic notification has demonstrated significant (> 30%) improvement in compliance with the glucose control guidelines. With appropriated implementation the automated notification panel for a tighter glucose control in post cardiac surgery patients has demonstrated positive effect on quality of care.

Background: The tight glycemic control has been associated with reduction in an early mortality (death in ICU), incidence of complications, and length of stay in an intensive care unit (ICU). This impacts an overall quality of patient care and cost of hospitalization. Compliance with the glycemic control guidelines developed by the surgical care improvement project (SCIP) of Centers for Medicare and Medicaid Services (CMS) is suboptimal. **Aim:** To develop the automated electronic medical records (EMR) tool for improving compliance with the SCIP-4 metric.

Methods: The automated notification panel for ICU health care providers was developed as an application within the existing AWARE Clinical Desktop Application. The study took place at Mayo Clinic, Saint Marys Hospital, Rochester, MN. The hospital operating room (OR) DataMart database was employed as a primary data source to track the patient path in a hospital and extract the data on the glucose level and critical event history. The measurement of outcomes was a percent of compliance with SCIP guidelines over the 4 months period of time. The measurement of quality of care was the glucose level less than 180 mg/dL in two 6 hour periods within the 18-24 hours after the anesthesia end time (AET). Patients who were dismissed from the ICU within 24 hours of the anesthesia end time, deceased, left against medical advice, required cardiac pulmonary resuscitation, or required further surgeries were excluded from the study. The User Interface contained the set of information boxes: i) monitoring windows for the patient location; ii) insulin interventions; iii) laboratory results with trends with a spark line and optional full size visualization; and iv) timer for 12 to 18, and 18 to 24 hour periods after the AET. Notifications were designed to have specified colors according to the status hierarchy (‘warning’ - yellow, ’fail’ - red, ’pass’ - green, and ’excluded’ - grey), and AET date (Figure 1).

Results: Two nurses in a surgical ICU had access to the beta-version of the automated glucose status notification panel for 4 months. The glycemic control data were analyzed for 448 pre-implementation and 433 post-implementation patients. The number of noncompliance cases declined from 48 to 31. Compliance with the glycemic control was 10.92% and 7.57% pre- and post- panel incorporation respectively (p=0.06). The analysis of cases of noncompliance with guidelines identified the 3 main reasons for failures: i) spike increase in a glucose level immediately at the end of the 18-24 hour period; ii) failure to obtain glucose measurements; and iii) poorly controlled diabetes mellitus at the baseline. The analysis also demonstrated that compliance with the tight glucose control 12-18 hours after the AET was associated with a better glucose control 18-24 hours after the AET.

Conclusions: The automated glucose level notification tool facilitated the better glucose control, especially, in the most complex ICU patients.

. Lack of statistical significance in improvement of metric compliance is likely due to a small number of testing providers. Improvement of the tool implementation process is required.

GeneAnswers: Integrated Translational Interpretation of

Gang Feng, PhD[1], Pan Du, PhD[2], Xishu Wang, MS[3], Jing Wen, MS[4], Tian Xia, PhD[5], Warren A. Kibbe, PhD[6], Simon M. Lin, MD[7]
[1]Northwestern University, Chicago; [2]Genentech, San Francisco, CA; [3]International Trading Group, Chicago; [4]Greenline Financial Technologies, Chicago; [5]Huangzhong University of Science and Technology, Wuhan, China; [6]National Cancer Institute, Bethesda, MD; [7]Marshfield Clinic, Marshfield, WI

Description

It is not enough for most researchers to identify one or multi- groups of interesting genes or units from current clinical and translational studies. People expect more advanced concept analysis, such as functions and pathways, for groups of given genes. Our team has developed a new R-compatible Bioconductor package, GeneAnswers, to automatically present potential correlations between interested genes and specified concepts (functions, pathways, diseases, etc) based on statistical test. Besides Gene Ontology, KEGG pathways database, EBI Reactome pathway database and caBio pathway database that is more specific and up-to-date resource integrating NCI-Nature curated pathways, Biocarta and Reactome. Besides this, Disease Ontology, which is derived from NLM Unified Medical Language System (UMLS) and developed by our group and collaborators, is also supported by the current version GeneAnswers. Customized concepts from biological studies or clinical information can also allow users to perform own concepts enrichment tests in GeneAnswers and identify the potential relationship between given genes and the novel findings in biology and medicine. The package GeneAnswers can not only visualize the network between potential concepts and interested genes as well as gene interactions, but also uniquely combine optional data matrix (such as gene molecular profiles) and relative concepts together. With the support of Entrez eUtils, people can find the links connecting the given genes to customer-specified keywords so that possible biomarkers could be identified for validation. Moreover, homologous gene mapping function makes it possible for piloting experiments based on animal models to apply the achievements on human being. Furthermore, computer-generated multiconcepts-genes table is introduced to integrate concepts analysis for correlated groups of genes (such as time course study). For efficient visualization of our knowledge, a "wordle"-like strategy is also developed and integrated in GeneAnswers, which includes text-mining based know information preprocess. The package GeneAnswers, combining Gene Ontology, varies of pathway databases and NLM based Disease Ontology with gene interaction information as well as customized annotation support, is truly helpful for people to gain an insight into clinical diagnosis and remedy at molecular and genetic levels.

Using Electronic Health Record Access to Infer Physician Follow-up After Handoffs

Stephanie Feudjio Feupe Msc; Robert El-Kareh, MD, MS, MPH
University of California, San Diego

Abstract

Introduction

Physicians benefit from feedback of patient outcomes to help calibrate their diagnostic and therapeutic decision-making and learn from their errors[1]. This benefit may be especially pronounced for physicians in training, however we know that many resident physicians do not get adequate feedback of patient outcomes.[1,2] Fragmentation in care leads to lack of a longitudinal view of the effectiveness of initial management plans. Despite these barriers, an electronic health record (EHR) can enable more efficient follow up of patient outcomes. We sought to use EHR data to determine how often emergency medicine (EM) and internal medicine (IM) residents follow up on their hospitalized patients after handing their care off to other providers and to describe factors related to this follow-up.

Methods

We obtained IRB approval for our project and obtained consent from 22 EM and 40 IM residents to study their chart access histories. We identified patients who were hospitalized at UC San Diego Heath System between December 16, 2012 through April 30, 2013 and cared for by at least one of the consenting physicians. We identified handoffs using the treatment team assignment data in our EHR. We linked these data with resident rotation assignments. We measured the earliest time that the physician handing off the patient's care to another provider subsequently re-accessed that patient's electronic chart. We generated descriptive statistics to evaluate the post-handoff chart access relative to physician, patient and encounter characteristics. We performed a preliminary logistic regression analysis of IM resident re-access controlling for patient age and gender, level of care that the patient required , resident year of training, rotation assignment, and whether handoffs occurred prior to discharge, on a weekend and during off hours.

Results

We analyzed records for 6075 handoffs involving 2406 patients during the study period. Overall, residents re-accessed patient charts within 14 days following handoffs in 111/3581 (3%) cases for EM residents and 1394/2494 (56%) cases for IM residents. For IM cases, we found that senior residents were significantly less likely to re-access charts compared with junior residents and interns with an odd ratio (OR 0.5795% CI 0.47-0.67, $p<0.001$). Compared with daytime residents on ward rotations, re-access of charts occurred significantly less frequently for EM residents (OR 0.03, 95% CI 0.02-0.05, $p<0.001$) and IM residents on night admitting rotations (OR 0.23, 95% CI 0.17-0.32, $p<0.001$). In addition, re-access was significantly more likely if the handoff occurred prior to the patient's hospital discharge (OR 2.99, 95% CI 2.45-3.64, $p<0.001$).

Discussion

We found that EM residents and IM residents who admitted patients overnight were least likely to re-access patient charts within 14 days following their handoffs of patient care. For many patients, the initial diagnostic and therapeutic decision-making is performed by residents on these rotations. Therefore, these residents may benefit the most from feedback of the results of their decisions. These results suggest the need to create a more reliable system for providing patient outcome feedback to physicians in training.

Understanding the Dispensary Workflow at the Birmingham Free Clinic: Responding to Challenges with Informatics Interventions

Arielle Fisher[1], Gerald Douglas[1], PhD
[1]Department of Biomedical Informatics, University of Pittsburgh, Pittsburgh, PA

Abstract
Objective: *Provide formal documentation in the form of work models of the routine pharmaceutical workflow at the Birmingham Free Clinic (BFC).* ***Methods:*** *We used a contextual inquiry methodology to document the current workflow and facilitate the identification of critical aspects of intervention design specific to the user.* ***Results:*** *A total of three pharmacists were observed and interviewed at the BFC. Work processes that may benefit from the introduction of informatics interventions were identified. Maintaining medication stock levels, medication dispensing, patient counseling, and effective use of the EMR for patient prescription information were identified as candidate areas for informatics interventions.*

Introduction
The Birmingham Free Clinic in Pittsburgh, PA is an organization designed to serve uninsured and other medically vulnerable groups through the use of a volunteer group of health care providers. This clinic offers a variety of services including primary care, chronic disease management, physical exams, and medication access and management through an in-house dispensary. The introduction of an electronic medical record (EMR) has improved several aspects of workflow in the free clinic, such as the ability to better document patient visits and archive prescriptions. However, many of the pharmacists' everyday tasks regarding the dispensary and medication management have become more challenging since the EMR was introduced. While the implementation of the EMR is intended to increase patient safety and quality of care, benefits cannot be fully realized due to the inability of the EMR to support workflows between the clinical service and the dispensary. We hypothesize that inefficiencies that exist in the current dispensary workflow at the BFC may potentially be alleviated by a series of informatics interventions. In order to identify workflow inefficiencies and propose interventions, a detailed understanding of the free clinic workflow and the needs of the key user, the pharmacist, is necessary.

Methods
Contextual inquiry is a qualitative, user-centered, social method designed to identify and understand users' needs and is used for collecting, interpreting, and aggregating in-detail aspects of work [1]. Pharmacists were observed and interviewed at the BFC according to contextual inquiry guidelines. Notes describing the overall workflow in the BFC, common breakdowns and inefficiencies, photos of physical artifacts, and detailed information regarding specific dispensary processes were collected during observation sessions. Five graphical models were produced to aid data visualization including sequence, flow, artifact, physical and cultural models.

Results
A total of three pharmacists were observed and interviewed at the BFC. Notes from a total of three observation sessions lasting approximately 3-4 hours each were documented and analyzed. The current dispensary workflow at the BFC is labor intensive and lacks efficiency when integrating with the clinical service. Observations identified processes that may benefit from the introduction of informatics interventions including: maintaining medication stock levels, medication dispensing, patient counseling, and effective use of the EMR for patient prescription information.

Future Work
We will identify a rank order of workflow inefficiencies as perceived by three pharmacists who have experience working in this setting and define informatics interventions designed to address the highest-ranking inefficiencies.

Title: Using HIE Data to Calculate Quality Measures for Public Health Surveillance

Authors: Elaine Fontaine, BS, Rhode Island Quality Institute, Providence RI 02908
Jonathan Leviss, MD, Thundermist Health Center, West Warwick, RI

Problem/Purpose: Disparate data systems across stakeholders in the healthcare system result in siloed views of quality metrics, focusing on either insured subpopulations or Meaningful Use measures reported by the provider community. Payers rely on claims for case identification and measure achievement for insured patients. Providers are dependent on their electronic medical record to identify both denominators and numerators. Public health agencies have access to limited data from payers and providers, making it difficult to evaluate overall compliance with agreed upon standards of care across a broad population. The goal of this project is to explore the differences in rates calculated using standard claims and EMR data and to begin to assess the suitability of health information exchange data as an alternative approach to assess statewide performance on quality metrics.

Methods: Data collected from Current Care, Rhode Island's Health Information Exchange, is being analyzed to calculate a statewide Chlamydia Screening Rate for women 16-24. Upon enrollment in Current Care, patients are uniquely identified using QuadraMed's master patient index software; thereafter clinical data automatically flows into the HIE from 90% of Rhode Island labs, all Rhode Island adult acute care hospitals, 90% of Rhode Island pharmacies and over 40 doctor's offices . At the time that this preliminary analysis was conducted, there were approximately 270,000 patients enrolled in Current Care. Using data from patient enrollments and continuity of care documents from primary care offices, a denominator was generated based on the patient's age and gender, regardless of payer or primary care physician relationship. A numerator was generated based on evidence of laboratory testing for Chlamydia. These rates are compared to health plan reported rates and rates reported by practices participating in Rhode Island's Patient Centered Medical Home project, the Chronic Care Sustainability Initiative (CSI), which relies on electronic medical record data for denominator and numerator identification.

Results:

	Current Care	Rhode Island Commercial and Medicaid Plans [(1)]	CSI Practices Reporting with EMR Data
Measurement Period	CY2013	CY 2006	CY2013
Denominator	11,303	12,729	1,600
Numerator	3,663	---	957
Rate	34.2%	44.5%	59.8%

Conclusion: These results suggest that the overall screening rate for patients in the Rhode Island Current Care population may be lower than reported by other sources, including health plans. Key items to consider as we advance this analysis include selection bias of Current Care enrollees, differential screening rates for uninsured patients, and/or completeness of HIE data.

Do Consensus Abstracts Agree with Meta-Analyses or Systematic Reviews?

Paul Fontelo, MD, MPH, Raymond F. Sarmiento, MD, Raymonde C. Uy, MD, MBA, Fang Liu, MS
National Library of Medicine, Bethesda, MD

Abstract

We reviewed whether conclusions from systematic reviews and meta-analyses agreed with those derived from Consensus Abstracts, a tool for finding relevant, validating abstracts and bottom-line (TBL) summaries. A crowd-sourced evaluation found that only 66% were concordant. However, a review of discordant results showed that only 2/33 reviews were considered marginally discordant, subject to interpretation. The most common reasons of disagreement were: unresolved medical controversies, incorrect search methods, inappropriate selection of abstracts, and erroneous conclusions.

Introduction

'Consensus Abstracts**'** (CA) is a Web and mobile application that finds related, validating abstracts that may be useful for clinical decision making.[1] For clinicians in low resource settings interested in evidence-based medicine, CAs may be more useful. Using simulated cases, a recent study among resident physicians in a developing country showed that the accuracy of clinical decisions improved equally using abstracts alone or full text articles.[2] Moreover, even those who stated that accumulated knowledge or "stock knowledge" alone were adequate, sought evidence. Whether or not consensus abstracts reach the same conclusions as systematic reviews or meta-analyses was raised recently.[3] Although the CA's algorithm is designed to include systematic studies (Cochrane reviews, systematic reviews, and meta-analysis), we wanted to find out whether Consensus Abstracts based solely on original publications (i.e., systematic studies excluded) reach the same conclusions as more systematic studies. If CAs will be a key source of evidence, it is essential that conclusions derived agree with synthesized evidence sources.

Methods

Through a Web interface, reviewers selected a clinical topic then chose one or both CA search tools, i.e., PICO or *ask*MEDLINE, to search and retrieve citations from PubMed. Filters were added to remove citations without abstracts, Cochrane reviews, systemic reviews, and meta-analysis to simulate instances where no systematic studies were found and the clinician relying solely on abstracts and bottom line summaries. Reviewers selected as many citations as considered essential then compared the conclusion derived from them with those from preselected systemic reviews or meta-analysis articles from high-impact journals (Lancet, NEJM, JAMA, etc.). All selected citations, and conclusions were stored in MySQL tables for review by the authors. All discordant topics were reviewed and the reasons for discrepancies were determined. All the clinical topics were also searched with the regular CA search tool to establish if a PubMed/MEDLINE search would retrieve systematic level studies.

Methods and Discussion

Although there were only 18 topics searched, some were reviewed more than once totaling 33 reviews. Thirteen of 33 (39%) reviews were discordant. An analysis showed that the most common reasons for discordance were: incorrect formulation of clinical questions, incorrect search terms, inappropriate selection of abstracts, erroneous conclusions and unresolved medical controversies. Each of the 18 topics retrieved between 1-12 systematic studies.

Conclusion and Lessons Learned

Poor search and appraisal skills accounted for most disagreements. Search retrievals can vary widely depending on terms used and the formulation of clinical questions. In PICO, searches that are too specific limit retrievals and may even retrieve none. Clinicians need to be more familiar with "Related Items" in PubMed because it is useful for finding relevant articles. It is evident from this study that searching medical literature is an art and skill that need to be taught and developed among healthcare providers so they can practice evidence-based medicine better.

Title: Using Mental Models To Teach Public Health Informatics Evaluation In An Applied Training Fellowship

Authors/Degree: Laura H. Franzke, PhD, MPH; Herman Tolentino, MD; and Sridhar Papagari Sangareddy, MS
Affiliation: Centers for Disease Control and Prevention, Public Health Informatics Fellowship Program**,** Atlanta, Georgia

Abstract (50-75 words): Mental models allows for a shared language and conceptual representation of evaluation concepts when teaching informatics trainees. Mental models representing form and function of a public health information system (IS) assists in visualizing concepts and learning. Specifically, dissection of an IS into form and function facilitates problem formulation and application of methods, tools, and techniques to the evaluation problem. Use of two mental models in an applied fellowship demonstrates their utility for teaching IS evaluations.

Description: Public Health Informatics trainees come from very diverse backgrounds. Mental models allow use of a common language and shared conceptual representations of evaluation problems. Living (e.g., human body) and non-living (e.g., computers) systems can be understood in terms of form (how its components are assembled together) and function (how the components work together to achieve specific tasks). Evaluations of information systems including those used in public health (PH) can be framed according to an understanding of their form and function. Two mental models to aid evaluation of IS in PH are based on the Onion Ring Model (ORM) and the Information Value Cycle (IVC). Dissection of an IS into form and function facilitates problem formulation and application of methods, tools, and techniques to the evaluation problem. Use of these frameworks in an applied fellowship demonstrates their utility for teaching IS evaluations.

Building the Clinical Personalized Pragmatic Predictions of Outcomes (Clinical3PO) Pipeline Within U.S. Department of Veterans Affairs (VA)

Lewis J. Frey, PhD[1], Leslie Lenert, MD[3], Augie Turano, PhD[4], Wim Cardoen, PhD[5], Sean Igo, MS[2], Richard Bradshaw, MS[2], Scott Duvall, PhD[6]
[1]Department of Public Health Sciences, Medical University of South Carolina, Charleston, SC; [2]Biomedical Informatics, University of Utah, Salt Lake City, UT; [3]Department of Medicine, Medical University of South Carolina, Charleston, SC; [4]Department of Veterans Affairs, Pittsburgh, PA; [5]Center for High Performance Computing, University of Utah, Salt Lake City, UT; [6]Internal Medicine, University of Utah, Salt Lake City, UT

Problem

The U.S. Department of Veterans Affairs (VA) Informatics and Computing Infrastructure (VINCI) has 20 million patient records within its electronic health records system. The vital sign measurements alone consist of over a billion measurements. While the growth of data offers significant benefits to research, it does add an additional load to the VINCI computing capabilities. The adoption of a big data system enables the use of commodity hardware to perform analysis with greater sample sizes and better management services while reducing wait times for the production and analysis of datasets.

Introduction

This poster presents the design and deployment of the Clinical3PO environment within the VA. Leveraging their experience working within the VA technology infrastructure, the authors provide vital information on connecting to the vast amount of data collected on VA patients to improve health outcomes and advance data mining. Clinical3PO pipeline is an open-source big data system that enables large-scale analysis of medical data, particularly the VA data.

While maintaining veteran's privacy and security, data from all the Veterans Hospitals are organized and integrated within a central data warehouse and made available for research through VINCI. This includes patient care encounters/visits; Unified Medical Language System tagging codes derived from Natural Language Processing (NLP) for both clinical and administrative data elements; vitals; laboratory tests; clinical notes; procedures; medications; and a host of other medical measurements collected from patients enrolled at veteran hospitals. VINCI has been growing at a substantial pace providing researchers and clinicians access to vast amounts of medical data in a convenient and secure environment. VINCI has 20 million patient records within its EHR system. The preponderance of records are encoded from 2002 to present and includes approximately 12 million patients with large amounts of laboratory data. The vital sign measurements alone consist of over a billion measurements. Currently VINCI supports 2696 users and over 1278 projects.

Given the existence of an integrated system that has compiled, curated and tagged health data on millions of patients across United States, the opportunity exists to deploy novel and extant data mining approaches to improve predictive capabilities and outcomes within the Veterans Affairs (VA) system.

Methods

To minimize the burden on limited VA research resources, new code development takes place on an external test bed that simulated the VA environment. The external test bed is encoded on the Amazon Web Services (AWS) along with a non-VA publicly available intensive care unit dataset mapped to the Observational Medical Outcomes Partnership (OMOP) data model. After initial testing, code is migrated to the VA system through a remote login connection. The current VA Hadoop platform is Horton DataWorks 2.0 and consists of 5 Dell machines containing 2 processors with 4 cores each and 144 Gigabyte of RAM, running the Red Hat 6.0 operating system. There is one name node and 4 data nodes in the current environment with a total of 40 Terabytes of storage and the systems are connected using 1 Gigabit Ethernet.

Conclusions

Using external test bed approach enables rapid code development without directly interfacing with the VA hardware environment, thus, providing a flexible environment to explore software configurations and algorithms without using limited VA research resources.

A Layered context model: a basis for customized treatment – a GDM patient case study

Adi Fux[1], MA; Mor Peleg[1], PhD; Pnina Soffer[1], PhD; Mercedes Rigla[2], MD

[1]Department of Information systems, University of Haifa, Israel

[2]Endocrinology and Nutrition Dept., CSPT, Hospital de Sabadell, Sabadell, Spain

Abstract. Clinical guidelines (CPGs) provide evidence-based treatment options based on patient's clinical context. A guideline-based Clinical Decision Support System (DSS) matches a patient's clinical data with the clinical knowledge represented as a computer-interpretable guideline (CIG) to provide patient-specific recommendations. Physicians try to provide personalized treatment recommendations by different methods such as adjusting the recommendations to suit the patient's personal situations, to abide with his personal constraints, such as availability level of family support, and his personal preferences regarding side effects of medications. To support such personalization, CIGs would need to be customized to address not only the clinical context but to include also personal context and preferences. Yet it is important to stress that the (evidence-based) clinical context should remain the primary contextual aspect that determines the treatment options.

Our aim is to develop a decision model that will help physicians define the treatment recommendations based on the specific clinical context and personalize the recommendations, using other contextual aspects.

Background. DSS crosses the patient's data from the medical record with the CIG's medical knowledge to provide patient-specific recommendations. The medical staff manually adjusts the treatment recommendations based on the preferences, personal context or additional considerations, such as comorbidities. Our goal is to support physicians in this adjustment task by defining a layered context model that will refer to different context layers hierarchically and provide personalized treatment recommendations.

Research Question. How can we develop the layered context model to present personalized recommendations, based on clinical and personal patient's context?

Methods. We have been developing a layered context model using PRO*forma* CIG. Each layer uses the same candidates and decisions. Layer 1 includes primary arguments e.g. BG trend, BG level 1 hour after meal etc., to define the primary layer recommendations. Layer 2 includes secondary arguments e.g. routine level, support level etc., to define the secondary layer recommendations. The net results of recommendations from both layers define the specific recommendation. To demonstrate the approach we have used an example of Gestational Diabetes (GDM) and personal context to personalize the patient's treatment recommendations.

Results. The results of the personalized treatment recommendations are presented in Table 1. The first layer provides the clinical-based treatment recommendations. The personal context layer changes the number of measurements per day, exercise level, and consequently the expected blood glucose level (highlighted in the table) to provide specific recommendations for patient routine and support changes.

Table 1.layered context model

Personal Context	Affected objects	
Routine diet or schedule AND NOT Good metabolic control	Fasting BG	70-100 ml/dl
	Expected BG Threshold	70-120 ml/dl
	Measurements	3-4 times per day, every day
	Physical activity	mild to moderate exercise (1-6 MET), 0.5-1 hour each time, 3-4 times a week
Semi routine diet or schedule AND NOT Good metabolic control	Fasting BG	70-100 ml/dl
	Expected BG Threshold	70 - 140 ml/dl
	Measurements	2-3 times per day, every day
	Physical activity	mild exercise (1-3 MET), 0.5-1 hour each time, 3-4 times a week

Layer 1:

decision :: 'BG_measurement_per_day' ;
  candidate :: 'three_times_per_day' ;
    argument :: confirming,**BG_trend_state** = improve_and_below_threshold attributes
  recommendation ::netsupport(BG_measurement_per_day, three_times_per_day) >= 1;
  candidate :: 'four_times_per_day' ;
    argument :: against,**BG_trend_state** = stable_below_threshold attributes
  recommendation ::netsupport(BG_measurement_per_day, four_times_per_day) >= 1;
end decision.

Layer 2:

decision :: 'BG_measurement_per_day' ;
  candidate :: 'three_times_per_day' ;
    argument :: excluding,patient_routine_level = routine AND petient_support_level = frequent attributes
  recommendation ::netsupport(BG_measurement_per_day, three_times_per_day) >= 1;
  candidate :: 'four_times_per_day' ;
    argument :: confirming,patient_routine_level = routine AND petient_support_level = frequent attributes
  recommendation ::netsupport(BG_measurement_per_day, four_times_per_day) >= 1;
end decision.

Discussion. Gómez et al. [1] use a first layer to define the specific options that will be used in the second layer, without affecting them. In our model the first layer defines the treatment recommendations and a set of valid goals and options. In the second layer we will reason about the effect of the secondary considerations to provide specific treatment recommendations. The effect of the second layer may change the goals or the options and provide other valid options, more suitable to the secondary considerations.

Acknowledgement. This project has received funding from the European Union's Seventh Framework Programme for research, technological development and demonstration under grant agreement no. 287811.

Configuring Health Information Exchange Identity and Consent Services for Operational Use in a Changing HIE Landscape

Jason Gagner, MBA, Darren Mann,
Shan He, PhD, Neil Web, Greg Gurr, Sidney N. Thornton, PhD,
Intermountain Healthcare, Salt Lake City, UT

Abstract

The Health Information Exchange (HIE) landscape continues to evolve. The proximal roadmap for interoperability includes compatible network to network connectivity including vendor-operated exchange networks. Data services for HIE identity and consent management originally designed for central network connectivity have been refactored to allow multiple component architecture configuration options to support the diverse network requirements and organization-specific operational constraints. Logical processing has been added to the services to capture and track the transactional value added by the HIE services.

Introduction

During early 2011 Intermountain Healthcare entered into an HIE collaborative effort with the Care Connectivity Consortium focused on using open source tools that would allow for the beginning developments of a patient identification servicers that could be utilized across the country and consumed by any provider regardless of their EMR configuration. One of the goals for the collaborative effort was to simplify the process and reduce the overhead needed to manage patient matching and consent from external care providers. With the recent emergence of the exchange partnerships such as eHealth Exchange, competitive EHR vendor exchange networks, and Carequality, the immediate HIE reality will require interconnected networks rather than a single dominant network. Conservative organizational data security constraints have also limited the widespread adoption of open services for identity management outside the entity's firewall. Additionally, participating exchange organizations require return-on-investment transparency to justify expanded participation.

Methods

The components supporting identity and consent services have been reconfigured to work in three primary workflows so as to broaden the ability of adoption by provider EMR's regardless of geographical location or vendor: 1) Distributed services behind organizational firewalls; 2) Sponsored services behind a sponsor's firewall; and 3) In-parallel services to augment EHR-vendor HIE services. Logical processing and transactional reports have been configured to monitor the impact of the HIE services beyond the capability and constraints of the host network.

Results

Through the restructuring of the component architecture, the implementation and consumption of the HIE services for identity and consent management have increased from one organization using central network services in 2013 to early 2014 implementations of 2 organizations with distributed services, 3 additional organizations implementing the sponsored configuration;1 organization using the in-parallel configuration; and more under active consideration. Moreover, configuration challenges with onboarding to the e-Health Exchange Network have been resolved by shifting from central services to distributed configurations. Data collected from the return-on-investment logic are being included in multiple studies determining trait sensitivity and identification efficiency.

Conclusions

To increase the number of participating networks and organizations, HIE services for patient identification and consent have been adapted for flexible, distributed configurations. Logical processing can support transactional return-on-investment reports.

Development of the Medication Image Library (MIL)

Robert Gale, RpH, MBA

Introduction

A Medication Image Library (MIL) has been developed by the Veterans Affairs (VA) Consolidated Mail Outpatient Pharmacy (CMOP) to establish and maintain a library containing pharmacist verified, standardized, high quality images of all medications and products dispensed by the VA to our Veterans. Included in the library are prescription medications, over the counter (OTC) medications, medical devices, medical supplies, nutritional agents and all medications and products dispensed by the VA to our Veterans. MIL launched in June 2011 with the creation of the first standardized images using existing VA medication and product pictures. Currently the library contains over 46,000 images representing over 17,000 VA medications and products. MIL has photographed over 10,000 VA medications and products for the library.

Background

The Medication Image Library (MIL) was started to support the VetLink self-service Kiosks that were developed in response to the VA T21 Transformation Initiative, "Enhance the Veterans Experience and Access to Health Care". MIL will provide medication and product images for the VetLink Medication and Allergy Review Module. MIL's database and images can also be used to assist with Veteran education, Veteran medication reconciliation and the processing of Veteran prescriptions.

Objective

1) Improve Veteran learning through visual medical references. 2) Aid to Veterans and their health care team in medication reconciliation to help reduce adverse drug events 3) Standardization of medication descriptor and imaging procedures, tool to standardize imaging and descriptor naming across the VA. 4) Use of high quality images to improve the accuracy of processing and verifying Veteran prescriptions.

Process

85% of the medications and products that the Veterans receive are filled through the seven CMOPs. MIL is located within the Great Lakes (GL) CMOP, Hines, IL, allowing it to have access to a large variety of VA medications and products. VA medications and products not stocked at GL-CMOP are obtained from the other six CMOP's and also from visiting Hines VAMC, Jesse Brown VAMC and the Lovell Federal Health Care Center, which are all located in the Chicago, IL area. This close relationship with the CMOP's and VA outpatient pharmacies, allows MIL to stay up-to-date when new VA medications and products enter the VA system or when style changes occur with existing medications and products. Currently MIL contains 99.5% of the medication and products used by the CMOP's and 95% of the medications and products used by the VAMC to fill Veteran prescriptions.

System for 'Intent-to-Treat' Analysis in a Real-world Setting

Purav B. Gandhi, MBBS, MBA[1], Amarinder S. Sidhu, BE, MBA[1]
[1]ConvergeHEALTH by Deloitte, Newton, MA

Abstract

Real-world datasets have multiple challenges such as inconsistencies in quality and lack of quality. An 'Intent-to-Treat' Analysis was performed on such dataset sourced from electronic medical records and other secondary sources, to compare superiority of one medication over another in a retrospective fashion, for comparative effectiveness research.

Introduction

With growing amount of data due to EMR adoption, better technology to gather and harness data, and increased computational power to analyze the same, researchers have increased access to real-world evidence for comparative effectiveness purposes.

There are a number of challenges with regards to analyzing the data and generating reliable insights due to inconsistencies in the quality, lack of continuity, etc. There are multiple challenges associated with aggregating, normalizing and loading this data into a platform for analysis.

Method

We, at ConvergeHEALTH, have developed an active data surveillance system to monitor clinical effectiveness and drug safety related information for treatment medications available in the marketplace using secondary information captured from electronic medical records and other sources of real-world evidence. We leveraged this platform to double de-identify data from a healthcare system, and load it into a normalized structured data warehouse. Next, we configured a visualization application to load two select patient cohorts on different medications.

Boundary condition for the cohorts were defined based on the 1) diagnosis codes, 2) prescription of drugs to be compared, 3) index date based on the first prescription, 4) washout periods to select a treatment naïve patient cohort, 5) observation and reference period for measurement of the outcomes, and 6) propensity matching algorithm to balance cohorts. A certain set of pre-defined outcomes relevant to the disease area were tracked to measure superiority of one medication over another.

Results

'Intent-to-Treat Analysis (ITT)' evaluating superiority of one medication over another was performed. This was achieved by tracking multiple health outcomes relevant to the disease area over the period of entire observation period in the visualization application.

Discussion

Experiments of this nature bring into question various aspects of an ITT analysis, and its applicability for retrospective research on a real-world dataset given they are not as controlled and regulated; with the expected dropout percentage being much higher than clinical trials. However, eventually the goal of comparative effectiveness research would be to have an analysis that can account for non-compliance due to multiple reasons while evaluating the safety and effectiveness of a medication.

Conclusion

'Intent-to-Treat Analysis' provides a view in what is the expected performance of a medication in a real-world setting after accounting for all the patient factors that drive non-compliance.

Future Plans

We intend to compare the results of this analysis with various published observational research studies to identify the key similarities and differences.

Development of a Community Care Information System: A Case Study in Singapore

Alex Gavino, MD[1], Na Liu, PhD[1], Deepa Rengarajan[1], Kharel John Rebada[1], Liming Bai, MS[1], Eugene Shum, MBBS, MPH[2], Alfred Wu, MS[1]
[1]SMU-TCS iCity Lab, Singapore Management University, Singapore; [2]Eastern Health Alliance, Singapore

Abstract

We present a preliminary case study for the development of a community care information system (CCIS) for a regional health system in Singapore. The CCIS aims to increase the productivity of the medical-social care team during their home visits to clients who are enrolled in their community care program. Using the action design research approach, the iCity Lab proposed a design method for the CCIS and developed an information system that addresses the various processes of the program and the dynamic user requirements.

Introduction

SMU-TCS iCity Lab is a research collaboration between Singapore Management University (SMU) and the Tata Consulting Services (TCS). Our aim is to study future trends and directions in urban development and develop appropriate information and communications technology (ICT) solutions that bring better quality of life to people. We developed the City Process Management (CPM) framework[1] to guide us in creating innovative solutions for future cities. We focused on healthcare and ageing to demonstrate and prove the CPM framework in various sectors of the city. In Singapore, we are facing new challenges due to an ageing population, growing incidence of chronic diseases such as diabetes, and decreasing size of households. This trend changes the needs of a city resident and hence affects services which the city should offer to its residents.

We partnered with a regional health system in Singapore to extend our assistance to their community care program for clients with high care needs, vulnerable elderly persons and at-risk residents. In this program, the community care team (CCT) conducts an initial home visit to assess the social and medical needs of the resident. The CCT then creates a personalized intervention plan based on the initial assessment. Follow-up home visits and calls are made to monitor the status of the client. All encounters with the clients are documented using paper-based forms and notebooks. Our lab designed a community care information system (CCIS) to help the care team in their record-keeping and retrieval of client data.

Methodology

We used an action design research method which leads to the building of innovative information technology artifacts in an organizational context and learning from the intervention while addressing a problematic situation. Consecutive meetings with the CCT allowed us to understand their workflow and needs. After the initial user requirements gathering, our software development team created an initial version of the CCIS within 2 weeks and demonstrated the solution to the CCT. Comments and recommendations by the CCT were noted and incorporated in the next iteration. This process was repeated over a total of 3 months in order to better address the requirements of the end users.

Results and Discussion

Based on the user requirements, the following capabilities were needed in the CCIS: collect patient information and assessment data through digital forms, create client goals and intervention plan, remind the CCT of tasks for the clients, track the client encounters through an occurrence log, and provide a dashboard for reports. We are currently alpha-testing the CCIS. Further enhancements will be made once the CCT provides us with feedback based on their use of the system in the field.

Machine Learning Made Easy with Sherlock

Thomas Ginter[1,2], Olga V. Patterson, PhD[1,2], Ryan C. Cornia[1,2], Scott L. DuVall, PhD[1,2]

[1]VA Salt Lake City Health Care System; [2]University of Utah, Salt Lake City, UT

Introduction

Natural language processing (NLP) tasks commonly employ various machine learning (ML) algorithms to create statistical language models for document classification, information extraction, and an array of other purposes. A wide variety of ML algorithms and accompanying frameworks have been developed. Each framework comes with its own feature vector representation and associated objects to support the unique workflow and features that are provided. This diversity of implementations introduces a barrier for NLP system developers when attempting to incorporate a ML step into an NLP system. Each implementation, being unique to the algorithm it supports, is rarely reusable across NLP projects. Additionally, implementations of a feature vector that will work for one ML framework will need to be recoded to work for another, even if the feature set does not change.

This poster introduces the Sherlock ML framework that provides a common infrastructure optimized for text processing with ML algorithms regardless of the ML framework used..

System description

Sherlock is an extensible ML framework based on and compatible with the Apache Unstructured Information Management Architecture (UIMA).[1] Sherlock simplifies ML algorithm integration into UIMA-based NLP pipelines and takes full advantage of the scalability and flexibility of UIMA AS by providing modular and reusable building blocks for a ML workflow. The modules utilized in both training and prediction workflows include feature vector generation, training, and prediction.

Standardizing a feature vector representation is the most important factor in seeking to create a reproducible and translatable system across ML frameworks. Sherlock provides a standardized feature vector representation that can be stored for later use and shared across multiple ML frameworks in different pipelines or in the same pipeline. While this representation has been standardized, Sherlock does not impose any limitations on the scale or methods of calculating feature vectors on the given inputs. With Sherlock, developers only need to engineer a desired feature vector once to use any of the ML frameworks. We developed a feature vector implementation for bag-of-words approach.

Sherlock feature vectors are consumed for prediction and training by ML framework-specific implementations of a vector translator interface defined in Sherlock. Vector translators can be written to allow nearly any ML framework to interact with Sherlock. We have developed vector translators for LIBSVM and Mallet CRF implementations of ML algorithms.[2,3] Once a Sherlock vector translator has been created for a specific ML framework, it is reusable across projects and feature vectors without the need for customized reprogramming.

To use Sherlock, an NLP pipeline is created that can extract the features of interest and generate a Sherlock feature vector. The training module stores a collection of these feature vectors and uses a vector translator to perform the training in the specific ML framework using a training set or k-fold validation. With a trained model, the same NLP pipeline is used and the feature vector is used in the prediction model for classification.

With Sherlock, NLP developers can easily incorporate ML with reusable feature vectors and interchange ML frameworks.

Impact Of Implementation Efforts on AWARE Checklist Compliance

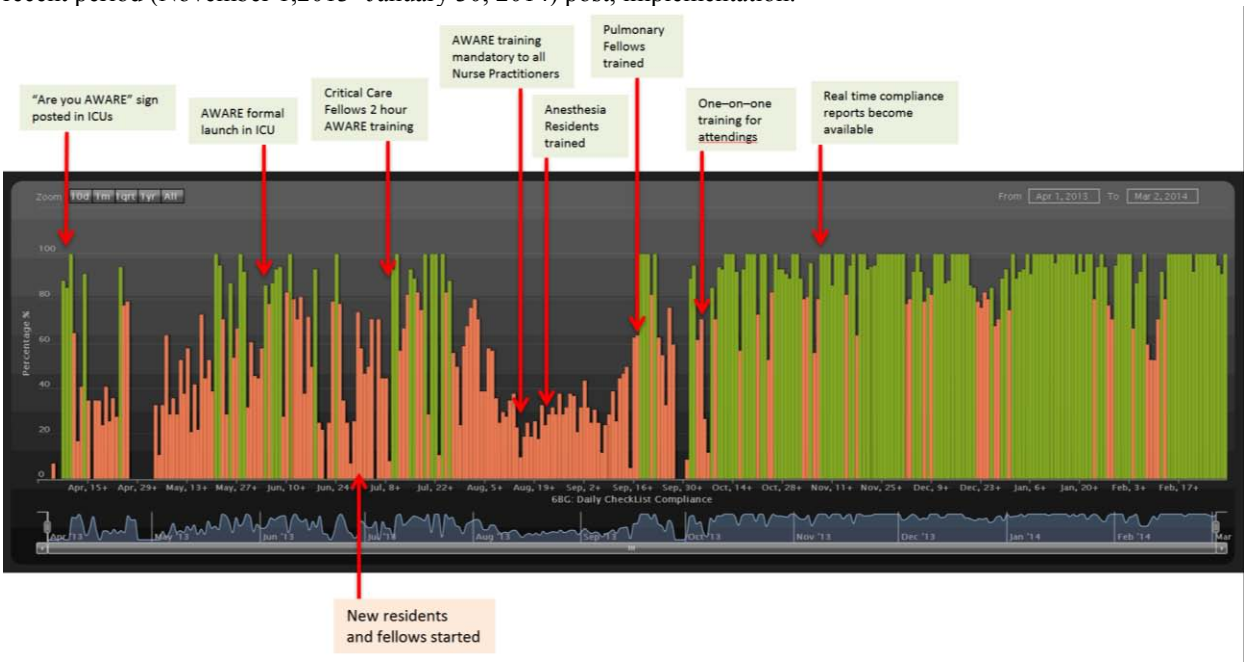
J. Giri MD, J. O'Horo MD, MPH, R. Sevilla Berrios MD, M. Resner, V. Fedosov MD, PhD, V. Herasevich MD, PhD, O. Gajic MD, B. Pickering MD,
Mayo Clinic, Rochester, MN

Abstract: An electronic checklist in AWARE, a novel Electronic Medical Record (EMR) viewer, was formally introduced in four Intensive Care Units (ICU) at the Mayo Clinic in April 2013. Initial adoption was low, leading to a variety of implementation efforts aimed at improving checklist adoption. The highest and most sustainable compliance of the checklist was observed 7 months post implementation efforts.

Introduction: AWARE is a data integration and decision support tool developed for the ICUs at the Mayo Clinic. In a pilot study, AWARE was shown to decrease the amount of time spent in data gathering by the providers, thereby decreasing workload [1]. The implementation of any new electronic system for clinical care is critically impacted by organizational, workflow and technological factors [2]. Training, information technology support, practice size, and choice of EMR were cited as some of the significant organizational factors affecting implementation [3]. We recently implemented a new feature on the AWARE platform, a best practice checklist aimed at improving care in the ICU.

Methods: The novel EMR viewer AWARE was designed with a context sensitive best practice checklist for ICU patients. Prior to the formal checklist launch in April 2013, we of designed educational materials, sought various committee and leadership approvals to formalize training, and trained physician providers at various levels. The impact of the various implementation efforts was closely monitored in the medical ICU. Recognizing challenges throughout the implementation process and low compliance led to using several plan-do-study-act (PDSA) cycles. Levels of checklist use, as well as each PDSA cycle change, are presented in the figure The rates of checklist compliance were used as the outcome of interest.

Results: The checklist compliance rates steadily progressed from 28% in the initial period (June 1, 2013- August, 30, 2013) to 64% in the late period (September 1, 2013 – November 30, 2013) and eventually above 78%, in the recent period (November 1,2013- January 30, 2014) post, implementation.



Conclusion: In order to achieve consistent compliance with the checklist, multiple interventions were required. The significant interventions included training and education, familiarity with electronic tool and involving leadership at every stage of intervention. We now have to focus on finding methods to sustain this impact and export the model to other units

Data Driven Approach to Vital Sign Parameters at Lucile Packard Children's Hospital Stanford (LPCH)

Veena V. Goel M.D.[1], Sarah F. Poole[2], Terry S. Platchek, M.D.[1], Christopher A. Longhurst M.D., M.S[1,2], Paul J. Sharek, M.D., M.P.H.[1], Jonathan P. Palma, M.D., M.S.[1,2]
[1]Lucile Packard Children's Hospital Stanford, Palo Alto, CA;
[2]Stanford University School of Medicine, Palo Alto, CA

Background
Multiple reference ranges exist for age-stratified pediatric vital signs. These vital sign parameters, although widely accepted in both inpatient and outpatient pediatric clinical settings, result in a large number of out-of-range heart rate (HR) and respiratory rate (RR) measurements among hospitalized children, which contributes to alarm fatigue. We aim to establish safe data-driven HR and RR parameters for hospitalized patients at Lucile Packard Children's Hospital (LPCH) Stanford, and evaluate the proportion of out-of-range LPCH vital signs that result.

Methods
Vital sign data (HR and RR) were extracted from the LPCH clinical data warehouse for all non-ICU hospitalized patients <18 years old during calendar year 2013. The data were stratified according to patient age, and a balanced random sampling of the data from each of the 7,202 unique patients yielded 62,508 vital signs measurements. Using these measurements, data-driven 5th and 95th percentile ranges for HR and RR were established and compared to the ranges published by Bonafide et al.[1] using a similar method. A validation cohort of 2,287 pediatric patients at LPCH from January to May 2014 was constructed. The LPCH data-driven HR and RR limits were applied to all 82,959 HR and RR measurements in this cohort to find the proportion of out-of-range results. This was then compared to the proportion of out-of-range results using the National Institutes of Health (NIH) 2004 norms, which currently define alarm limits by LPCH policy. Finally, HR and RR data were analyzed in 148 patients who had a rapid response team (RRT) or code event from March 2013 to March 2014 to determine how many patients had out-of-range measurements using the current parameters compared to the proposed parameters. In this population of patients, a true positive was defined as having at least one out-of-range vital sign during the 12-hour period leading up to the RRT or code event. Comparison was performed against randomly selected 12-hour periods in an age-matched control cohort of non-RRT/code patients.

Results
The HR and RR percentile tables developed based on LPCH patients were comparable to the curves developed by Bonafide et al. Most notably, the 95th percentile values for both HR and RR were significantly higher than current LPCH upper limits. Using calculated LPCH 5th and 95th percentile limits, 55.7% fewer measurements would have been considered out-of-range when applied to all HR and RR measurements in the validation cohort. Analysis of HR and RR data in the 12 hours leading up to RRT and code events demonstrated that 136 (94.4%) of the 144 patients who previously had out-of-range measurements were still identified as abnormal. Two additional patients not previously flagged as having any vital sign abnormalities were identified as having low HR values by the new limits. Eight patients previously identified as having high RR measurements were excluded by the new limits. Manual review of these patients' charts, however, showed that all 8 of the RRT/code events that would be within the new RR norms were not called exclusively for the reason of abnormal respiratory rate.

Conclusion
A large proportion of HR and RR values among children at LPCH are out of range according to current vital sign reference ranges. Our historical data suggest that adopting data-driven values for HR parameters will safely decrease the proportion of out-of-range measurements, and should decrease alarm fatigue by increasing the specificity of monitor alarms without decreasing sensitivity to RRT and code events. With regards to data-driven RR parameters, there was a slight drop in sensitivity towards detecting RRT and code events, and therefore future work to further tune these limits could be considered. We recommend this as the first step towards a more customized approach to inpatient bedside alarm fatigue reduction, consistent with a learning healthcare system philosophy.

A Qualitative Analysis of Patients' Behavior in an Online Health Community: Dynamics of Self-regulated Health Goal Achievement

Nadee R. Goonawardene, BSc[1], Sharon S L. Tan, PhD[1]
[1]Department of Information Systems, National University of Singapore, Singapore

Abstract

With the increased popularity of online social media platforms in healthcare, medical information sharing has become democratic and patient controlled. As a result, patients are more empowered and equipped with necessary information to proactively manage their health. Our research examines the factors that facilitate or inhibit the success of patients' self-health management efforts initiated in an online healthcare social network.

Introduction: Online social networks based on common health concerns are becoming increasingly popular. Virtual healthcare communities built on top of Health 2.0, have provided people with common interests a channel to gather virtually and share experiences, discuss treatment issues or guide and encourage each other to achieve individual healthcare targets. More importantly, for people who face challenges in developing self-regulatory behavior that is essential for self-health management, online health community participation may be useful in developing and motivating such behaviors. The objective of this study is to explore and evaluate how online health community participation can affect self-regulated health behaviors. In particular, we would like to explore the question: "How could Health 2.0 help individuals set and achieve their health management goals in developing self-regulated health behaviors? What are the dynamic relationships between goal setting, online social support and goal achievement?"

Methodology: This study adopts a qualitative research methodology to address the identified research questions. Data was gathered from Dailystrength.com, which is a popular community based healthcare website comprising of 500+ special interest groups. Data from the special interest group of obesity was chosen for the analysis. Obesity requires a substantial amount of self-health management, including life style modifications and self-monitoring. Therefore, we believe that such patients possess the required level of motivation in-order to set goals and continue to work towards achieving it. Individually created goals (i.e. lose weight goals) from 1026 profiles were gathered and a total of 786 completed or given-up goals were chosen for the analysis. Information such as: goal descriptions, progress updates, comments, moods and the anticipated end dates of goals were extracted. In the first phase, 'open coding' was carried out to extract important themes and variables. Then, 'selective coding' of all the data was carried out based on the core variables found at the open coding stage.

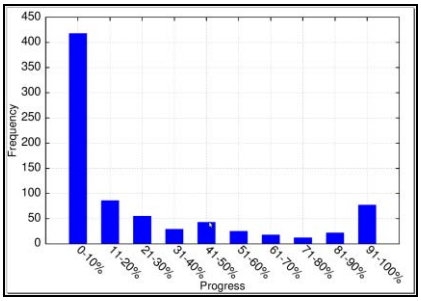

Figure 1. Last updated goal progresses

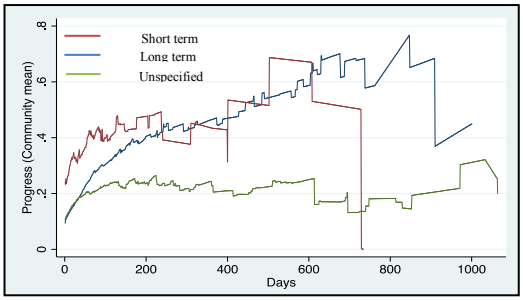

Figure 2. Community means distribution for three types of goals

Preliminary results: As illustrated in Figure 1, the highest number of goals has ended with little progress. By charting the goal progression for all the goals, we found six goal achievement patterns. A follow up investigation is then carried out to validate whether certain goal progression patterns are more likely to result in goal completion and how goal characteristics, mood and types of social support interact to influence progression and subsequent success in goal achievement. Based on the anticipated completion date, goals were divided into three categories: Long-term, short-term and goals with no deadline. Figure 2 shows the mean progression of these three categories across the community. Our data is consistent with the extant research on goal achievement whereby short-term goals mobilize efforts sooner and guide individuals to achieve goals faster. In contrast, long-term goals make it easy to postpone efforts; therefore the goal progress rate could be slower compared to short-term goals. The successful completion of our research can provide recommendations for healthcare practitioners in designing efficient online health management programs.

Longitudinal Tracking of Pain Phenotypes in Electronic Health Records Using an SVM

Clare T. Grasso[1], Anupam Joshi, PhD[1]
[1]University of Maryland Baltimore County, Baltimore, MD

Abstract

Mining electronic health records (EHR) holds great potential to increase patient safety and quality of care. Most natural language processing (NLP) systems for extracting data from medical text rely on the underlying grammatical structure of the text. However, text from EHRs is oftentimes grammatically incorrect or incomplete, contains many nonstandard abbreviations, and is interspersed with other semi-structured text. This research focuses on a new approach that does not rely on the underlying grammar.

Introduction

As computer-readable clinical health data becomes increasingly available through the use of electronic health records (EHRs), the potential to mine this data for health safety, quality of care, surveillance, and clinical decision support (CDS) systems is very great[1]. Most natural language processing (NLP) systems developed for extracting medical concepts rely on the grammatical structure of the formal text[2]. However, these systems can have difficulty with the weak grammatical structure of clinical narratives. For example, the free-form clinical text entered by physicians, nurses, and other health professionals is filled with sentence fragments, missing punctuation, many nonstandard abbreviations, and is interspersed with structured and semi-structured text such as lab results and questionnaires. Instead, we developed a machine-learning approach for extracting concepts from the clinical narrative that does not rely on underlying grammar.

Methods

For this project, the data consisted of ten patient histories from the Baltimore VA Medical Center's VISTA EHR. A number of medical conditions were represented. Each history spanned several days and contained a sequence of 50-100 different notes pertaining to the clinical encounters during a hospital admission, and included notes from several different types of health care providers including physicians, nurses, radiologists, surgeons, and physical therapists.

The prototype system focused on increasing patient quality of care by tracking references to patient-reported pain, including the severity, location, onset, and duration in the hospital record. Each line of text was labeled as positive or negative for the existence of any of these elements, and was preprocessed to remove punctuation and digits. The text was tokenized by white space and then featurized using the log of the term frequencies of unigrams and bigrams. A SVM was trained on these features and tested using ten-fold cross validation.

Results

This new approach achieved precision, recall, and F-score greater than 70% in discovering references to patient-reported pain in clinical narratives.

Electronic Consenting Program

Timothy E. Grose, BS, Ronald L. Jenks, BS, Wes D. Kincaid, BS, Miguel Restrepo, PhD
Moffitt Cancer Center, Tampa, Florida

Abstract
Identifying subjects that meet inclusion criteria for a specific research protocol and consenting them are critical to protocol success. Integrating our enterprise scheduling, registration, and protocol management systems aided us in matching a patient to a trial more quickly and efficiently. To make this a paperless process, capturing 21 CFR, part 11 compliant electronic signatures was imperative. Interfacing with enterprise systems assures notifications of protocol accruals are distributed appropriately.

Introduction
An open source application has been developed that integrates our enterprise registration, scheduling, and protocol management systems to facilitate the accrual process to protocols. Patients meeting the inclusion criteria for a protocol are identified by filtering on attributes stored within these systems. Connection with our scheduling system allows us to identify where and when a patient can be located for a study. The application provides protocol specific educational materials and consent documentation which can be electronically signed; over the internet or within the facility, complying with 21 CFR part 11[1]. After consenting, the distribution of the accrual to other enterprise systems reduces the amount of manual processes needed in management of the patient enrolling on a protocol.

Subject Identification
Using existing HL7 interfaces from our patient registration, scheduling, and protocol management systems we then select attributes of inclusion to filter patients to a targeted cohort. These attributes could be demographic or other limited clinical attributes. The scheduling integration joins the patients in the cohort to their appointments so we know when and where the patient can be found. Integrating the protocol management system provides additional attributes to identify patients who require consenting to new versions or amendments to the protocols they are already accrued to.

Patient Encounter
During a patient encounter, protocol specific education materials are presented to the patient within the application. The consent document is then presented and electronically initialed and/or signed where required. At the completion of the consenting process a copy of the consent can be sent via email to the patient. In the event of a non-consenting patient the encounter result is recorded to know how to approach the patient at a future opportunity. Examples of these would be those who deferred, declined, or the consent process was interrupted.

Electronic Signature Capture
We have two CFR compliant ways to electronically capture the patient's signature: guided and un-guided. Guided signature capture is done capturing a graphical signature with the Consentor at the patient's side. Un-guided signature capture is accomplished when patients accrue to non-therapeutic trials over the internet. To assure CFR compliance[1] an account is created by the patient using unique identifiers to verify the patient is who they identify as.

Consent Distribution and Notification
Once the consent is signed it is transformed to a PDF and centrally stored on the enterprise network, making it available for reference by other systems. Metadata regarding the consent process is sent via HL7 message types to the protocol management system which electronically creates a consent record for patient management on the study. Additionally, an update is sent to the electronic medical record which is then capable of auto-ordering additional research specimens when a specimen collection event occurs for the patient.

Conclusion
The consolidation of our hospital enterprise systems facilitates the finding of patients and reduces the time required to document accruals. Interfacing the hospital systems and electronically creating the consent records has reduced the hands-on time required for patient management on our protocols.

How to de-identify a large clinical corpus in 10 days

C. Grouin, PhD[1], L. Deléger, PhD[1], J.B. Escudié, MD[2], G. Groisy, MD[2], A.S. Jannot, MD, PhD[2,3], B. Rance, PhD[2,3], X. Tannier, PhD[1,4], A. Névéol, PhD[1]

[1]CNRS UPR 3251 LIMSI, Orsay, France; [2]AP-HP, University Hospital HEGP, Biomedical Informatics and Public Health Department, Paris, France; [3]INSERM U1138, Université Paris Descartes, Sorbonne Paris Cité, Faculté de médecine, Paris; [4]Université Paris Sud, Orsay, France

Abstract

To de-identify a large corpus of clinical documents in French supplied by two different health care institutions, we apply a protocol built from previous work. We show that the protocol can be installed and executed by outside collaborators with little guidance from the authors. The automatic de-identification method used reaches 0.94 F-measure and human validation requires about 1 minute per document.

Introduction

Clinical corpora are useful for scientists to develop natural language processing methods for the clinical narrative. In order to ensure the robustness of those methods, access to real data is a critical point. As clinical records contain personal health information, de-identification tools have been designed to help protecting privacy.[1]

Methods

Herein, we apply the protocol we designed to rapidly de-identify a new set of clinical records:[2] new documents to be de-identified are automatically pre-annotated with a statistical model built on similar resources. For new documents from the same hospital as our previous study[2] (corpus 1), we directly apply a model built with 100 training documents. For documents coming from a distinct hospital (corpus 2) we iteratively build a model as follows:

1. 20 documents were de-identified automatically, using a rule-based method[3] for the first iteration and a CRF (Conditional Random Fields) model for subsequent iterations, and manually validated by scientists and physicians

2. a statistical (CRF) model was built using all the manually validated de-identified documents available from all iterations. The latest model is then used for the next iteration of step 1. The features used to build the CRF model include surface features *(case, punctuation, digit, token length, etc.)*, deep features *(part-of-speech, lexical look-up, etc.)*, and external features *(position of the token in the record, cluster id).*

For the initial seed corpus of 20 documents, six different types of clinical notes were chosen to ensure robustness: 3 medical certificates, 3 consultation reports, 3 exam certificates, 3 hospitalization reports, 5 follow-up care letters, and 3 staff consultation reports.

Results and Conclusion

Corpus 1: The automatic de-identification method reached 0.94 F-measure and human validation required less than 1 minute per document for 800 documents. Corpus 2: About 1 day was needed to install the tools to use in the de-identification protocol. The automatic de-identification method reached 0.92 F-measure and human validation required as little as 1 minute per document for 100 documents. Validation time decreased with annotator experience and improvement in the performance of the de-identification method (i.e. after more training documents become available as we progress through more iterations). The protocol can be executed by outside collaborators with no prior experience of de-identification. It provides adequate support for the de-identification of a large corpus requiring little time and guidance.

An Informatics Approach to Building a Surgical Residents Log

Michael J. Grove[1], PhD, Jeff Emch[1], MBI, Mark Engelstad[1], DDS, MD, MHI
[1]Oregon Health & Science University, Portland, OR

Abstract

Tracking of oral and maxillofacial surgical resident training experiences is reliant on non-standardized tools and methods resulting in compromised data for individual and program evaluation. To address this, we developed a domain ontology built on a SNOMED-CT foundation that drives a new resident surgical tracking log. Initial results are a new >7,000 concept domain ontology with properties linking surgical diagnostic and procedural experiences to a set of new educational concepts.

Introduction

Oral and maxillofacial surgery (OMS) is a surgical specialty that manages disorders of mouth, face, neck, and jaw. To maintain program accreditation and assess individual trainee progress, OMS trainees must log their surgical experiences, including disorders they have managed and procedures they have performed. Across all OMS training sites, current systems for logging and educational reporting are localized and non-standardized and rely on the use of payment coding schemes such as ICD-9 and Current Procedural Terminology (CPT). Reimbursement-based coding systems do not provide sufficient granularity of surgical experiences and do not always provide accurate clinical research data[(1)] . The consequence is a heterogeneous collection of surgical training data within and across programs that does not enable adequate assessment or comparison.

Methods

We are developing an ontology-driven OMS resident education log ("OMSLog") for use within the Oregon Health & Science University (OHSU) OMS training program and designed to scale for respective implementations at other OMS programs. The log has a blended architecture that consists of a browser interface for trainees to record their experiences, and faculty, and/or administrators to review and report on these events. The Java-based system is supported by a traditional relational database (RDB) back-end for data storage and reporting and a Resource Description Framework (RDF) triple-store for diagnosis and procedure data. Both the RDB and RDF triple-store are driven by a new domain ontology as terminological and semantic foundation. The initial ontology class hierarchy was developed by an OMS expert who incorporated domain-enhanced concepts into a curated SNOMED-CT extract.

Results

Current results are a 7,488 concept domain ontology being curated in the Protégé Ontology Editor environment. The ontology is modeled to represent surgical diagnosis and procedure activities and to characterize them according to a set of newly defined OMS educational categories. The use of the ontology provides increased granularity of surgical experiences and allows sophisticated classification of the educational characteristics of resident surgical activity for improved reporting capabilities. The ontology will also serve as a domain knowledge feedback mechanism and will support subsequent secondary use of de-identified data. Future steps include evaluating the ontology through graph metrics, demonstration of the ontology's logic structure to answer domain competency questions, and usability testing for the log user interface.

Automation in Healthcare: is Automation Bias a side effect?

Anupama E. Gururaj, PhD & Dean F. Sittig, PhD
School of Biomedical Informatics, University of Texas Health Sciences Center at Houston, Houston, TX, USA

Introduction: Use of automation in the healthcare industry has resulted in unintended errors that were not foreseen previously. Automation plays a prominent role in clinical decision support systems (CDSS) in the healthcare setting. CDSS acceptance and performance are determined by two end-user characteristics: 1) Trust in Automation that determines the extent to which CDSS is used and 2) Automation Bias (AB) that defines the tendency of the user to over-rely on automation. AB is one of the major underlying causes for errors during CDSS use (1). Therefore, a review of literature focused on studies exploring AB in healthcare is warranted.

Methods: A survey of PubMed literature using specific keywords relating to CDSS and medical errors such as "CDSS errors", "decision support system error", "error bias automation", "automation clinical decision support error", "automation error", "Sittig D", "Bates W", "Kaushal R error", "Kate Goddard" was conducted. The keyword selection was based on a quick survey of literature to determine the names of primary groups working on CDSS error identification as well as terms relating to error and AB. The titles and abstracts of the search results were manually scanned for appropriateness and inclusion. Articles were included if the studies commented on negative effects of CDSS in the medical domain only. Where possible, complete texts of the papers were retrieved and the texts were perused for relevant information. Resulting relevant literature was used to discuss and characterize the errors due to AB in the medical domain.

Results & Discussion: The PubMed search with the different keywords resulted in 2560 unique records that were retrieved. Of these, 22 were found to be relevant to the topic of study for which we were able to obtain full texts. To a large extent, studies defining AB in healthcare have focused on computer-aided detection (CAD) in radiology. Most of the studies showed heterogeneous results with reference to the effect of AB on errors. Modifiers that influence AB have been extensively investigated in other domains such as the aviation industry. A listing of these factors and their effects on AB is shown in Figure 1 which is a theoretical framework developed by Goddard et.al., based on the Theory of Technological Dominance (2). On the basis of our review of literature with regard to AB and its effectors in the medical domain, we have defined the primary role of four elements (encircled in red in Figure 1). Task inexperience lead to increased AB. AB increased when physicians were less confident of their own diagnosis and the converse was also found to be true. Therefore AB is a trade-off between self-confidence and trust in CDSS. Studies showed that increased task complexity increased reliance on CDSS and therefore increased AB. Detailed analysis of each investigation also underlined the parallels in etiology of AB between medical and other fields. Therefore, strategies that have been effective in mitigating AB in other domains (3) could be successful in healthcare too. Increased user accountability lead to decreased AB. Likewise, educating users of the reasoning behind DSS decisions and training users to be aware of appropriate reliance on the DSS reduce AB. The position of the DSS advice and relaying the decision as information rather than a command or recommendation decreases AB. Finally, decreasing screen details which translates to less clutter and more focused information decreased AB. Details of the studies determining mitigation strategies will be discussed in the poster. Given the potentially serious outcomes resulting from incorrect medical decisions, it would be beneficial to examine the negative impact of introducing automated clinical advice, as well as the overall positive effects of CDSS on medical decision-making.

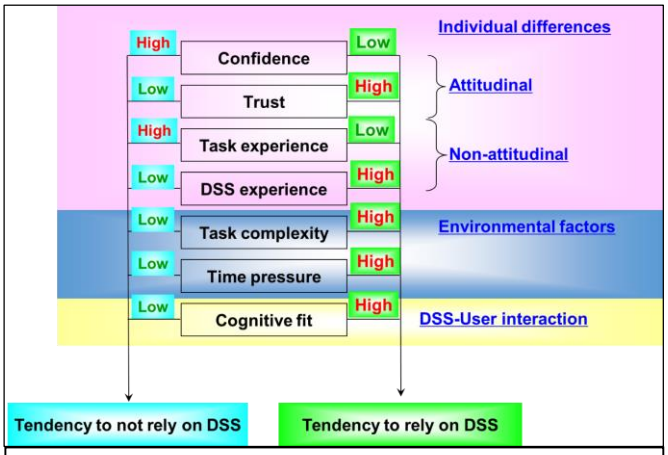

Figure 1. List of factors affecting AB as determined from all domains. The major players in the medical domain are encircled in red (Adapted from 2)

The Business Value of IT in Healthcare: The Case of Cleveland Clinic's Online Second Opinion System

Peter Haddad [1, 3], Jonathan Schaffer[2] Nilmini Wickramasinghe [1, 3]

[1]RMIT University, Melbourne, Victoria, Australia, [2] Cleveland Clinic, Cleveland, Ohio, USA, [3]Epworth HealthCare, Melbourne, Victoria, Australia

Abstract

In an environment of rapid development of new clinical informatics solutions claiming to provide better healthcare delivery, there is a paucity of systematic frameworks to robustly measure the actual value of these systems. The following proffers such a model grounded in the information systems literature and assessment of business value to address this significant void.

Introduction

Today numerous clinical informatics solutions are being designed and developed claiming to provide superior healthcare delivery. However, too many of these solutions fail and many are dubious regarding their real value. To address this void an integrated model to assess the business value of these systems is developed.

Defining Value in Healthcare Delivery

'Business value of IT' is used to refer to the organizational performance impacts of IT, including cost reduction, profitability improvement, productivity enhancement and competitive advantage [1]. While specific perspectives are a key to viewing the critical impact of any IT system, there are advantages from the business, administrative, technology and most importantly, clinical reference points such as patient experience. For healthcare deliver, access and cost are cruical. Further, value is often defined in terms of the expenditure outcome benefits, divided by the cost expenditure while benefits, from a patient's perspective, include the quality of healthcare outcomes, the safety of the delivery process, and the services associated with the delivery process [2].

The Proposed Model

In order to develop an integrative model that will assess the value of a clincial informatics solution, perspectives of healthcare value from the respective points of view of all key stakeholders must be considered. To operationalize the IT resource, the IT portfolio is classified into infrastructure, transactional, informational, and strategic [3]. From an organizational perspective, The Enterprise of Healthcare Delivery Model provides useful insights. Finally, it is necessary to recognize the socio-technical perspective of these systems at four interrelated levels: (i) Clinical practices (people); (ii) Delivery operations (processes); (iii) System structure (organizations); and (iv) Healthcare ecosystem (society) [4] which all must work togehter to provide a better patient experience.

To test the potential of the proposed model, the specific case of the MyConsult® second opinion programat the Cleveland Clinic is applied. The subsequent analysis serves to demontrate that not only does this highlight the strengths and value of the MyConsult program but it also serves to demosntrate the robustness of the proposed model.

Conclusions

There is a clear need for a systematic framework to assess the business value of clincial informatics solutions. To address this need, a suitably robust model is developed from various bodies of IS and business literature. The proffered model is then tested using the second opinion program developed at the Cleveland Clinic.

Automatic Extraction of Electronic Health Record System Data to Assist Evaluation of a Status Epilepticus Clinical Protocol

Baria Hafeez[1], Juliann Paolicchi[3,4,5], Steven Pon[2,4,5], Joy Howell[2,4,5], Zachary Grinspan[1,3,4,5]

[4]Komansky Center for Children's Health, Weill Cornell Medical College, New York, NY
[5]New York Presbyterian Hospital, New York, NY

Background: Status epilepticus is a neurological emergency characterized by unremitting seizures. Under these circumstances, immediate and precise actions are required to stop the seizure, and prevent brain injury. The Komansky Center for Children's Health has developed a "status protocol," which describes the suggested therapies to stop a patient from seizing. It is unclear the extent to which an evaluation of adherence to this protocol can be done electronically. Conducting such an adherence evaluation may be difficult because of the amount of data that needs to be reviewed. An automated tool to extract and display the data would have tremendous value both for quality assurance, to determine whether a protocol is properly being adhered to, and for research, to determine the effectiveness of the protocol. Electronic health record (EHR) systems may potentially solve the challenge of data collection and management to support evaluation of clinical protocols.

Methods: A retrospective chart analysis was conducted using information from the EHR system on a convenience sample of seven children with status epilepticus. We reviewed charts to qualitatively determine how well the data can be extracted and visualized. We used the R software environment, with the "timeline" package to visualize each patient's first 24 hours of care.

Results: Qualitatively, our observations are as follows: (1) most clinical data is well labeled in structured fields within EHR; (2) medication administration data is encoded in multiple places, with differing levels of detail and occasional inconsistencies; (3) the exact time of transfer from the emergency department to the intensive care unit (ICU) is not clearly indicated. However, this information can be inferred by searching for the first vital signs recorded in the ICU; (4) proxy measures need to be used to determine precise times of endotracheal intubation, arterial, and central line placement; (5) a "timeline" style visualization can rapidly clarify a patient's clinical course; (6) a clinical expert is needed to determine seizure onset and cessation; (7) free text EEG reports may not contain the exact time of seizure control.

Conclusion: Our observations indicate that several key elements of a protocol evaluation could be automated and visualized; however, manual chart review may still be necessary to obtain all the relevant data.

Linking Adenomas Between Colonoscopy And Pathology Notes For PROSPR

Scott Russell Halgrim, MA[1], Leslie Sizemore, BFA[1], Edward Pham, MS[1], Gabrielle Gundersen, BA[1], David S. Carrell, PhD[1], Karen Wernli, PhD[1], Jessica Chubak, PhD[1], Carolyn M. Rutter, PhD[1]
[1]Group Health Research Institute, Seattle, WA

Abstract

In colorectal cancer screening, the number and size of adenomas found drive the recommended follow-up interval, but are often only available in unstructured text fields and split across reports. We augment an NLP tool with heuristics related to colonoscopy processes to increase the system's ability to count and size adenomas.

Introduction

Colonoscopy is a colorectal cancer screening test whose follow-up time is largely based on the number and size of adenomas found[1]. At Group Health, this information is electronic text in the colonoscopy procedure and pathology reports; the pathologist determines if a polyp is adenomatous, yet the procedure note often has more accurate counts and sizes. We use a natural language processing (NLP) system to find results above size and count thresholds.

Methods

We used the procedure and pathology notes of 248 patients selected randomly from all 2011 colonoscopies with pathology at Group Health. The gold standard was created by manual chart review. To detect adenomas, we extended the GATE[2] system of Harkema et al[3]. With initial modifications, the system detected cases of adenomas with 96% sensitivity, but performed worse at identifying cases of multiple (three or more) or large (greater than 10 mm) adenomas. We describe changes made to find more of these cases.

Gastroenterologists group samples into jars by colon area and pathologists write reports accordingly. To find cases of multiple adenomas, we use this method: if a jar's location is unique in a report, the sample is described as "fragments," and all jar contents are described as adenoma, then we set the number of polyps in that jar to match the number in that location in the procedure report. We classify a case as having a large adenoma if all samples in a jar with a unique location are adenomas and the procedure report lists a large polyp at that location.

Results and Discussion

Table 1 shows inter-annotator agreement and how our rules improved sensitivity. Although our rules' conditions are strict, we find many more cases of interest with little loss in specificity. We plan to assess the system's portability by testing at other sites and assess the significance of these findings by testing on larger sample sizes.

Table 1. Sensitivity and specificity of the NLP system on categories of interest before and after adding heuristics.

Measure	IAA (Cohen's Kappa)	Original		Modified	
		Sensitivity	Specificity	Sensitivity	Specificity
Has 3+ Adenomas (N=46)	.917	.717	.990	.870	.960
Has Adenoma >= 10 mm (N=12)	.880	0.000	1.000	1.000	.983

Conclusion

Identifying count and size of adenomas detected during a colonoscopy is important in colorectal cancer screening. We increased our ability to count and size adenomas found by augmenting an NLP system with heuristics to synthesize information between the procedure report and the pathology reports.

Older Adults Use of Online and Offline Sources of Health Information and Constructs of Reliance and Self-Efficacy for Medical Decision Making.

Amanda K. Hall, PhD[1], Jay M. Bernhardt, PhD, MPH[2], Virginia Dodd, PhD, MPH[2]

[1]University of Washington, Seattle, WA; [2]University of Florida, Gainesville, FL

Abstract

We know little about older adults' use of online and offline health information sources for medical decision-making despite increasing numbers of older adults who report using the Internet for health information to aid in patient/provider communication and medical decision-making. Therefore we investigated older adult users and nonusers of online and offline sources of health information and factors related to medical decision-making. This study found significant differences between users and nonusers of online health information related to their preferred health information sources and examined factors related to online health information engagement for medical decision-making.

Introduction

Patients' interest in accessing and utilizing information to inform their healthcare decision-making and increase their healthcare knowledge and management is well known. However, prior to the World Wide Web, patients usually obtained information from healthcare providers, mass media sources, or local community members deemed knowledgeable about health issues. Today the Internet offers access to a wide range of disease prevention and health management information that can be a useful aid in decision-making. The literature contains few studies investigating health information sources, reliance for medical decisions, and the role of self-efficacy in medical decision-making between older American users and nonusers of online health information. To address this gap, this study (1) assessed the relationship between users and nonusers of online health information and self-efficacy for medical decision-making (2) examined the relationship between users and nonusers of online health information and their Reliance, either self-reliant or physician-reliant, for medical decisions, and (3) investigated the differences between users and nonusers of online and offline health information sources.

Methods

We conducted a survey using random-digit-dialing of Florida residents' landline telephones. Using the Decision Self-Efficacy Scale and the Reliance Scale, we measured relationships between users and nonusers of online and offline sources of health information.

Results

Study respondents were 225 older adults (age range 50–92, M = 68.9, SD = 10.4), which included users (n = 105) and nonusers (n = 119) of online health information. Approximately 75% of all respondents sought information regarding health from offline *healthcare professionals* followed by the *Internet* (46.9%). However, users and nonusers differed in frequency and types of sources sought. Users of online health information preferred a self-reliant approach and nonusers of online health information preferred a physician-reliant approach to involvement in medical decisions on the Reliance Scale, $t(218) = -.3.09$, $p = .001$. No significant differences were found between users and nonusers on the Decision Self-Efficacy Scale.

Conclusions

More empirical research is needed to extend the literature on the use of the Internet as a patient decision aid for medical decision-making. As the Internet continues to be a predominate source of available health information, further research is needed to test constructs that predict use of online health information to bridge information and communication gaps between healthcare providers and older adult patients for improved health outcomes and shared medical decision-making.

Coordination-Based Analysis of Inter-Unit Handoffs

Saira Haque, PhD, MHSA[1], Craig Kuziemsky, PhD[2]
[1]RTI International, Center for the Advancement of Health IT, Research Triangle Park, NC; [2] Telfer School of Management, Ottawa, ON, Canada

Abstract
Routines are repetitive patterns of action that guide organizational activities, including handoffs. Electronic health records (EHRs) are often designed based on ideal-type routines that do not match how activities occur in practice. The mismatch can lead to issues during transitions such as inter-unit transfers. We conducted observations of routines, participants and information sharing during inter-unit transfers at two institutions. Variations in patient severity, type of transfer, other activities occurring in the unit and the dependencies determine if deviations from ideal-type routines lead to issues in handoffs. Issues were mitigated by articulation work and clarity of roles and tasks in routines. Our findings can be used to support EHR design to support handoffs.

Introduction
Handoffs between units are points which are prone to errors and other issues [1]. Thus, it is important to understand more about the issues that occur in transfers to develop processes, systems and contingency plans for them. Conceptualizing the handoff as a coordination routine with multiple aspects can yield important insights into how issues with handoffs occur and how they can be prevented.

Methods: Site Selection
We studied different types of inter-unit transfers at a community hospital in the United States and an academic medical center in Canada. The community hospital handoffs involved transfers from the interventional cardiology unit to an inpatient nursing unit or to an outpatient unit. The academic medical center handoffs focused on transfers to the operating room (OR) and then from the OR to the recovery or patient care unit.

Results: Conceptual Framework
Table 1 shows the coding scheme used from a previous study [2]. Routines, or repetitive patterns of action, guide organizational processes such as handoffs and was used to establish the boundaries of the handoff for analysis. Coding is in process for different variations of routines and the coordination and work that exists within the routine in practice to validate the conceptual framework and coding scheme.

Table 1 – Coding Scheme to Analyze Inter-Unit Transfers

Concept	Description
Articulation Work	Work required to continue or go on
Coordination	Managing dependencies between tasks
Routine	Repetitive patterns of action that govern organizational work
Ostensive routine	The ideal-type or theoretical routine (policies and procedures etc)
Performative routine	The actual performances of the routine
Organizational routine	Patterns that govern work for a process throughout an organization
Coordination routine	Repetitive patterns of action used to manage dependencies

Conclusion
Errors and other issues in inter-unit handoffs occurred for a number of reasons. Varying ideas of the ideal-type handoff across staff led to inconsistency in processes made it difficult to integrate knowledge about patients and communicate that knowledge when the patient transitioned between units. Differences from ideal-types can occur because of communication and coordination issues, staff changes, other activities occurring in the unit or patient severity issues. Applying these related concepts to inter-unit transfers across institutions can help further understanding of errors in handoffs.

Connecting CCC to SNOMED CT and LOINC in a Terminology Server

Tiffany Harman, RN; Rachael Howe, RN; Tosh Kartchner, RN; Susan Matney, RN MSN
3M Health Information Systems, Inc., Murray, UT

Introduction

Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT) and Logical Observations Names and Codes (LOINC) have been mandated as the terminologies to use when messaging coded data between settings – SNOMED CT for coded problems and LOINC for outcome measures. Nursing data is key to providing a complete clinical patient picture. The Clinical Care Classification (CCC) is an American Nurses Association recognized nursing terminology. It contains nursing care components that provide the framework for classifying nursing diagnosis, interventions and outcomes. Linking to SNOMED CT and LOINC will allow the nursing data to be messaged.

The 3M Healthcare data dictionary (HDD) is a terminology server that houses the standard terminologies required to document clinical care, including SNOMED CT and LOINC. CCC can be added to the HDD and linked to SNOMED CT and LOINC to facilitate interoperability between systems.

Methods

A terminology model is designed to incorporate all of the CCC entities (care components, diagnoses, interventions and outcomes) as concepts, relationships and representations. Each CCC concept is given a numeric unique concept identifier (NCID) and appropriately related to each other. After all the CCC concepts are created in the HDD, relationships are built between the CCC concepts and SNOMED CT and LOINC concepts.

Results

The CCC terminology model encompasses 21care components, 60 major diagnoses, 77 major interventions, 116 sub-categories for diagnosis, and 124 sub-interventions. Each sub-diagnosis has three outcomes: improved, stabilized and deteriorated. Each sub-intervention has four action types: assess, perform, teach and manage. Figure 1 shows an example each for diagnosis and intervention.

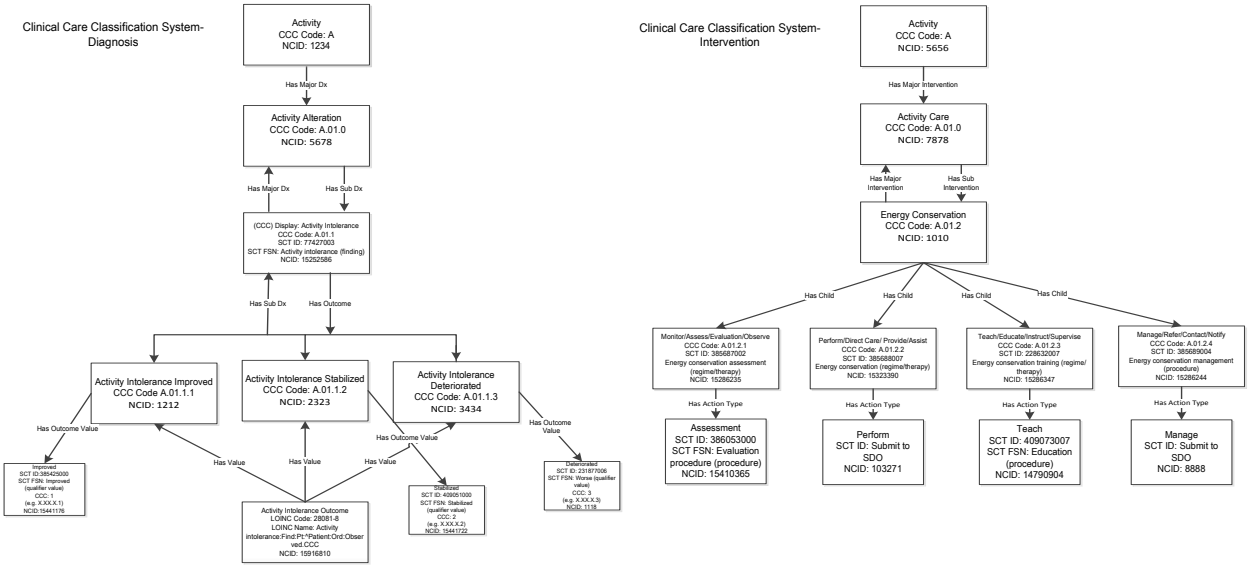

Figure 1

Conclusion

The HDD functions as a technology solution to implement standard terminologies. Incorporating the CCC within the HDD enables the continued use of CCC in systems and facilitates interoperability by providing terminology translations between CCC, LOINC and SNOMED CT. Continued use of standard nursing terminologies maintains nursing knowledge and promotes standardized documentation of the nursing process. The mapping to SNOMED and LOINC supports national messaging standards.

Development, testing, and refining the severe sepsis and septic shock sniffer

A.M. Harrison, BS; C. Thongprayoon, MD; R. Kashyap, MBBS; V. Smith, MD, A. Hanson, O. Gajic, MD, MSc; B.W. Pickering, MD, MSc; V. Herasevich, MD, PhD

Mayo Clinic Rochester and Mayo Clinic Arizona

Background: From 1979-2000, the incidence of sepsis in the United States increased from 164,000 to 660,000 cases[1]. Sepsis was also reported as the most expensive condition treated in US hospitals in 2011, with an aggregated cost of $20.3 billion.[2] However, current sepsis detection algorithms have not considered alert action in the context of failure to rescue.[3]

Objective: Develop and test an automated alert algorithm ("sniffer") for detection of severe sepsis failure to rescue.

Methods: Retrospective cross-sectional study using independent derivation and validation cohorts (Table 1). We examined all adult first-admissions to the medical ICU at Mayo Clinic in Rochester, MN, from January through March 2013 (N = 587).

Table 1: Cohort demographics

Variable	Derivation (N = 293)	Validation (N = 294)	P value
Age (± SD)	63.7 ± 18.5 years	63.3 ± 19.0 years	0.7936
Sex (% male)	52% (N = 151)	54% (N = 159)	0.5367
Hospital LOS, (± SD)	7.1 ± 6.7 days	7.6 ± 8.4 days	0.4426
ICU LOS, (± SD)	2.1 ± 2.6 days	2.2 ± 3.1 days	0.7081
SOFA score, Day 1 (± SD)	4.6 ± 3.5	4.5 ± 3.5	0.7201
APACHE III score, Hour 1 (± SD)	61.6 ± 25.6	59.1 ± 23.0	0.2275

Algorithm validation was performed against the "gold standard" of manual chart review by two trained reviewers, with one super-reviewer for cases of disagreement. Algorithm development and testing was performed using iterative recursive data partitioning and critical appraisal of false positive and negative alerts. The algorithm is based on the following variables: suspicion of infection, system inflammatory response syndrome, organ dysfunction (lactate and systolic blood pressure), and shock (vasopressors and fluid resistant hypotension).

Results: The ability of the first technical iteration of the severe sepsis sniffer on the derivation cohort to detect severe sepsis and/or septic shock was suboptimal: 59% sensitivity, 97% specificity, 92% Positive Predictive Value, and 83% Negative Predictive Values. Critical appraisal of false positive and negative alerts, along with iterative introduction of new clinical variables (mean arterial blood pressure, bilirubin, platelets, INR, mechanical ventilation, creatinine, PaO2/FiO2 ratio, urine output, GCS score, and fluid balance) into the algorithm, was then performed, which resulted in an increased sensitivity of 82%. Testing this algorithm on the validation cohort shows similar diagnostic performance (Table 2).

Table 2: Diagnostic performance of sniffer algorithm iterations

Algorithm	Sensitivity	Specificity	PPV	NPV
Algorithm 1 (Initial)	59	97	92	83
Algorithm 2 (Debugging)	82	97	93	92
Algorithm 3 (Validation)	80	96	92	91

Discussion: Current detection performance of our sepsis alert systems is similar to previous reports.[4,5] Recursive data partitioning and validation of the failure to rescue domain are anticipated to further refine the sniffer for eventual implementation in the clinical setting.

Conclusion: The validated sepsis sniffer showed sensitivity in good agreement with final derivation algorithm. However, this sniffer could be improved further by adding a failure to rescue component to the algorithm.

Pepparedsleden 1, SE-431 83 Mölndal, Sweden

It is well known that obesity is an important risk factor for type II diabetes. It has been shown for patients in a lifestyle modification program that weight loss is the most important predictor for reducing diabetes incidence [1]. Here we collect all relevant literature aiming to quantify the impact of weight loss on the risk of progressing to diabetes in patients with high risk for diabetes including different interventions and population types. We identified clinical trials on overweight or obese subjects with increased diabetes risk or pre-diabetes, treated with obesity drugs, lifestyle interventions or undergoing bariatric surgery. The material includes patients with an increased diabetes risk based on impaired glucose tolerance (IGT), impaired fasting glucose (IFG) as well as the FINDRISC scoring. Each study involved a weight loss phase of variable length followed by a follow up period of 1-4 years of changes in diabetic status. These criteria were met for 10 published clinical trials involving 9,811 overweight or obese subjects [2-11].

We extracted meta information on trial and population characteristics, as well as follow-up data on weight-loss and incidence of diabetes for both active treatment and internal controls. Exponential and linear models, to quantify the effect of weight reduction on diabetes incidence reductions compared with control, were fitted to the data.

Our results indicate that the association of diabetic risk was approximately linear for weight losses ranging from 0 to 10 kg, with an average risk reduction in the active arm of 8-13% compared with control for 1 kg average body weight reduction (corrected for weight loss in control group).

In conclusion, in this work we have gathered all available literature and quantified the risk reduction in progressing to diabetes after losing weight.

Thermia: Simplifying Childhood Fevers with Mobile Decision Support

Jared B. Hawkins[1,2], PhD, Jane E. Huston[2], MPH, Florence T. Bourgeois[2], MD, MPH, John S. Brownstein[1,2], PhD

[1]Harvard Medical School, Boston, MA, [2]Boston Children's Hospital, Boston, MA

Summary

We developed a decision support tool and mobile application to provide information on fever and febrile illnesses, such as respiratory and gastrointestinal illnesses, to concerned parents. The primary goal is to provide information on supportive treatment that parents can provide at home and guidance on when to seek medical care via web-based and smartphone apps. A secondary goal is to integrate user data into public health biosurveillance tools (e.g., HeathMap.org and FluNearYou.org), to better track emerging disease and provide tailored treatment recommendations. Our tool will motivate parents to take a direct role in their child's health care by providing education and information necessary to support their decision-making around children with fevers and infectious febrile illnesses.

Introduction

Over 2 million children die each year due to infectious febrile illnesses [1]. In addition, medical costs are staggering; in the US, influenza treatment alone for children is ~$1.7 billion annually [2], with emergency visits for children under 5 years of age accounting for as much as $289 million [3]. Active engagement of patients and their families has the potential to lower medical costs through improved patient literacy and resource utilization, and may ultimately lead to more favorable health outcomes. We believe that by educating parents and providing at-home decision support, we can enable parents to provide supportive care when appropriate and optimize efficient use of healthcare resources, thereby reducing unnecessary medical costs.

Methods

We developed a mobile decision support tool, named Thermia (http://thermia.io), to provide at-home treatment recommendations for fever and infectious febrile illness symptoms based on established guidelines from Boston Children's Hospital. Thermia is a rule-based web framework that engages parents to answer questions regarding symptoms associated with a febrile illness. The user then receives information on possible causes for the symptoms, signs of serious illness, home treatment recommendations, and guidance on when to seek medical care.

Results and Discussion

Researchers have previously shown that at-home decision support for streptococcal pharyngitis is a viable approach to triaging patients and significantly reducing unnecessary office visits [4]. We are now utilizing this approach for febrile illnesses - specifically respiratory and gastrointestinal disease - which has not previously been done before. The Thermia website soft-launched in January 2014, and has had modest use to date. The majority of users are seeking treatment recommendations for children less than 5 years of age with a fever and most common symptoms of cough and/or sore throat. We are currently working to iterate and improve upon our decision support framework, with the goal of making the user experience as intuitive and informative as possible; to this end; we are working with popular parenting online communities. Our next step is to integrate user data into public health biosurveillance tools, such as HealthMap.org and FluNearYou.org, which have been extremely successful in using crowd-sourced data to track infectious disease outbreak and enable real-time monitoring. Integrating user symptoms from our application will strengthen these public health systems with the addition of a new, previously untapped data stream containing emerging symptoms at a local, regional and national level. This will allow us to inform users of emerging respiratory diseases via our application, and recommend preventative and therapeutic measures in the case of a local outbreak. Our poster presentation will discuss our progress to date on these endeavors.

Streamlining Health Information Exchange Workflows through Automated Disclosure Control Services

Shan He, PhD[1], Darren K. Mann[1], Lance Schildknecht[1], Sidney N. Thornton, PhD[1, 2]
[1]Intermountain Healthcare, Salt Lake City, Utah; [2]University of Utah, Salt Lake City, Utah

Abstract

Patient consent remains an unintegrated and less automated component in the current health information exchange (HIE) infrastructure. Clinical workflows have been interrupted to procure administrative artifacts due to providers' fears and concerns associated with the potential misuse of protected health information (PHI). An automated solution that facilitates the reuse of existing data to enable compliant PHI disclosure is critical to streamline the HIE workflow while protecting providers from liability risks and preserving trust with patients.

Introduction

Although there are various specifications and services being developed to promote HIE, patient consent, which is central to the issue of privacy, remains unintegrated in the HIE infrastructure. For example, the Direct Project assumes that the sender is responsible for the collection of patient consent where appropriate, which is referred to as "out of band" verification[1]. Currently Intermountain Healthcare requires patient consent on file before disclosing PHI electronically to external providers. The collection of patient consent is time consuming and an interruption of the clinical workflow, which potentially limit the amount and type patient data available via HIE[2]. To alleviate the administrative burdens while addressing the privacy concern by preventing inappropriate disclosures, we are implementing a self-contained disclosure control service to automate the regulation-compliant PHI disclosures.

Methods

The automated disclosure control (ADC) service generates and enforces a set of rules for each PHI disclosing transaction in the format of when, what, to whom, for what purpose. These rules can be generated on the fly using existing data from various administrative and clinical sources during an encounter such as 1) the consent for treatment ; 2) current and previous care team participants; 3) Current episodic treatment/transition plans; 4) payer HIE stipulations. The key functionality in the ADC service is to automatically infer the treatment or payment relationship between the recipient of the disclosure and the patient based on the above information. When such relationships cannot be inferred, the clinician is required to provide supplementary attestation to justify the disclosure. Furthermore, the current proactive mechanisms for detecting potentially inappropriate EHR access can be reused to preempt suspicious disclosures. Finally, all disclosure details are audited by the ADC service. Even though the ADC service is designed to alleviate the need to collect patient consent, it is extendable to incorporate with structured patient consent to enforce the disclosure rules for situations when patient consent is collected (e.g. opt-out patients) or required (e.g. patient records maintained by federally assisted alcohol and drug abuse program).

Results

Regulation-compliant PHI disclosure via HIE is enabled by the ADC service when a valid treatment or payment relationship can be automatically inferred. The ADC service streamlines the clinical workflow by eliminating interruption of the care delivery process with unnecessary administrative tasks for the clinician. The ADC disclosure auditing provides transparency for patients and privacy advocacy for the healthcare providers.

Conclusions

A trade-off exists between the level of privacy assurance and the convenience of HIE participants. Leveraging automated services that minimize the administrative burden while maximizing privacy protection is critical for successful HIE adoption and sustainability.

A Qualitative Preliminary Study of Older Adults' Personal Health Information Tracking Behaviors

Yuqi He, MLIS
University of Wisconsin-Madison, Madison, WI

Abstract
Personal Health Records (PHRs) create great opportunities for older adults to track and manage their health; individual interviews with people age over 60 were conducted to gather information about their personal health information tracking behaviors.

Introduction
The current growth in the number and the proportion of older adults in the United States is unprecedented. By 2050, the over-65 population in the U.S. will increase to 88.5 million, representing one in five Americans.[1] 86% of older adults have at least one chronic disease, and 56% have two or more.[2] The aging population with high proportions of chronic conditions will increase demands on medical services and poses great challenges to our already strained health care system.

PHRs can be potential technologies to help track and manage health. PHRs may be a particularly useful tool for older adults because of increased occurrence of chronic diseases and the need for long-term care. Several applications, such as Project HealthDesign's Colorado Care Tablet (CCT),[3] were designed to help older adults manage medications. We lack knowledge, however, about individual factors of why and how older adults keep track of their health information, how they use this information, their perceived benefits, and under what conditions they decide to continue or stop tracking. To help design information technologies that promote health tracking by older adults, I conducted individual interviews to explore their personal health information tracking behaviors.

Methods
Ten subjects (4 males and 6 females) aged 60 or older participated in this study. Their educational levels ranged from non-completed high school to PhD degrees. Seven of them were White. Face-to-face, semi-structured interviews were conducted. Each interview lasted an average of 40 minutes. The sessions were recorded using a digital recorder. All interviews were transcribed verbatim. The transcriptions were analyzed using Nvivo 10. A grounded theory approach was used to analyze the data and develop a model of older adults' health information tracking process.

Results
Five components consisted of this behavior model: motivation, tracking & managing process, outcomes (information sharing and perceived benefits), decision (continue or stop), and social contexts (doctors and families). Motivations prompt older adults' tracking needs, which in turn initiate the tracking process. Three themes were identified: goal-oriented (e.g. chronic disease management, medication management, and keeping fit), beliefs and values (e.g. informed health consumer, self-responsibility), and health-related experiences (e.g. health event, family health history, age-related memory loss). Older adults used pillboxes, paper files, and electronic gadgets such as PHRs as tracking tools. Six perceived benefits emerged: improved accuracy, keeping conditions in control, medication adherence, good communication with doctors, self-evaluation, and positive emotional reinforcement.

Conclusion
Tracking behavior is a complicated, iterative process. Older adults become a more diverse population in terms of their physical capacity, psychological performance, and life style. Every subject's tracking behavior is unique, in terms of their motivations, tools use, and perceived outcomes. This implies that designing information technologies that try to capture all behavioral actions is inherently complex and practically impossible. This complexity may suggest a layered strategy for IT designers to design a personalized, customizable product for older adults.

Admission data predict risk as well as discharge data in patients with pneumonia: A readmission risk-model evaluation

Courtney L. Hebert, MD, MS[1], Peter J. Embi, MD, MS[1]
[1]The Ohio State University, Columbus, OH

Abstract

Real-time risk prediction using continuously updated electronic health record (EHR) data could help to target timely and personalized interventions. Few studies have examined how the change in patient-specific EHR variables on different days of a hospitalization might affect risk prediction. Using a previously validated readmission risk score on a cohort of hospitalized patients, this study describes how the score changes over time, and on which day the score is the most predictive of readmission.

Methods

The risk model used in this study was originally developed by our group to predict readmission in hospitalized patients with pneumonia on the day of discharge from the hospital. It was created using logistic regression with stepwise removal and performed well on a validation cohort (area under the receiver operating curve (AUC) 0.71). In addition to a history of prior admission in 30 days, variables in the final model included ones that could change over a hospitalization such as lab values, medications, number of medications and comorbidities. The model categorizes patients into high, medium or low risk based on their risk score.

This study applies the risk-model to a new cohort of patients admitted from 5/2012 to 1/2013 with a primary discharge diagnosis of pneumonia. Variable definitions were adapted in order to reflect risk per day of hospitalization. For example, the problem list was used to define comorbidities instead of discharge diagnosis billing codes (these only being available after discharge). The change in risk score for individual patients as well as the change in risk score over time was evaluated. An ROC test of equality was used to determine if change in AUC from different days of hospitalization was statistically significant.

Results

356 of 418 (85%) patients had a calculable risk-score (no missing values) on the day of admission. 274 (77.0%) patients had an increase in their score from the day of admission to the day of discharge and 72 (20.2%) patients had a decrease. Only 18 (5.0%) patients went from high or medium risk on the day of admission to low risk by discharge. 241 (67.7%) patients had no change in their risk category. The predictive model performed less well on this cohort with an AUC of 0.60 on the day of discharge. **Figure 1** shows the change in AUC over hospitalization. Overall, the AUCs of the model on different days were not statistically different with a p-value of 0.10.

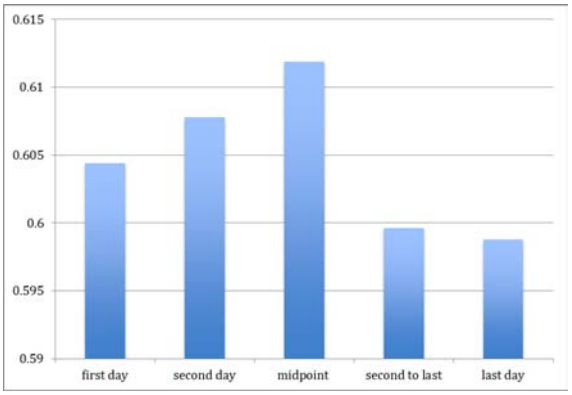

Figure 1: Change in AUC of model at different points during hospitalization

Conclusion

The predictive ability of the model varied minimally over the hospitalization, with the best performance at the midpoint of the stay. This suggests that, for this model, risk prediction earlier in the hospital stay would be reflective of the risk at discharge allowing for earlier interventions.

Design and Development of Team Builder –

Matching Funding Opportunities to Research Profiles

Andrew C. Helsley, BS[1,2], Robert A. Dennis, PhD[1,2], Marianne Zachariah, BA[1,2], and Douglas S. Bell, MD, PhD[1,2]

([1]Department of Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA, [2]UCLA, Clinical and Translational Sciences Institute, Los Angeles, CA)

The UCLA CTSI has developed a web-based open source system that mines NIH funding opportunity announcements (FOAs), processes salient passages of them with the National Library of Medicine's natural language processing tools to produce Medical Subject Heading (MeSH) terms that are then used to semi-automatically search against investigator web research profiles. We call this system the Team Builder, and we have engineered the basic components to address two similar use cases. The first begins with a funding opportunity announcement and the need to identify qualified investigators within our cross-institutional clinical translational science consortium. The second use case takes the perspective of an individual investigator who wishes to stay aware of possible funding opportunities that closely align with his/her area(s) of research. In both cases, the challenges are to match expertise as represented by a web-based research profile with a funding opportunity represented by its announcement.

Our poster will present the design and functionality of the Team Builder in the context of our initial work focused on the first use case. We have developed this system to leverage the rich data found in public research profiles with particular attention on MeSH keywords relating to publications. We have implemented a framework that processes NIH FOAs and combines them with the automatic classification capabilities of the Medical Text Indexer (MTI) to help improve the recall of staff research facilitators whose role is to invite qualified individuals to collaboration brainstorming session.

The central component of the Team Builder engine is the Unified Medical Language System (ULMS) and more specifically the Medical Subject Headings (MeSH. The MeSH terms are attached to publications and transitively to the authors of the publications. Team Builder associates MeSH terms with FOAs using the MTI. The result is a well-curated semantically meaningful common basis for matching the two together. Our initial user interface (UI) has been tailored with the recognition that pursuing a funding opportunity requires the participation of individuals in several different roles, and the raw output of MTI may not be completely satisfactory. Our UI allows staff to partition and augment the set of MeSH terms that are automatically associated with the FOA into smaller sets that are expected to improve the precision of the Team Builder beyond a simple fully automated approach.

The UCLA CTSI Team Builder has been developed using the open source framework called OpenACS. It is an advanced toolkit for building scalable, community-oriented web applications and services. OpenACS runs on OpenNSD or AOLserver, open source multi-threaded and high performance HTTP servers with an embedded TCL scripting language.

After reading our poster and ideally speaking directly with one of the co-authors, the learner will be better able to:

- Formulate a plan to implement a similar approach to making meaningful use of his/her institutions research profiles system and publically available NLM tools to match qualified investigators with high-value funding opportunities
- Decide whether to adopt our approach and software and request access to our source code to implement at his/her own institution

Use of an Iterative Search Strategy in Critical Care Informatics

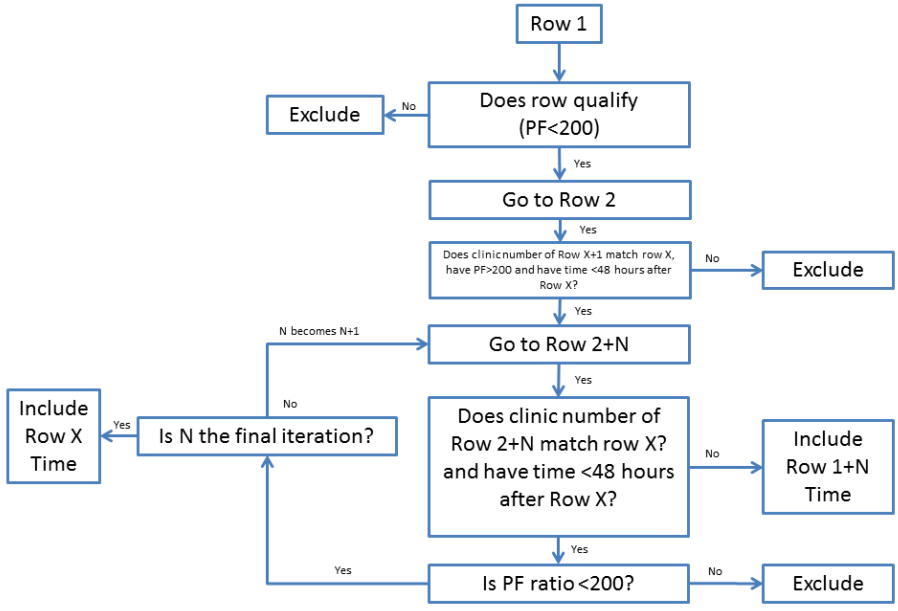
S. Kaur MD, LY. Garcia Arguello MD, JC. O'Horo MD, O. Gajic, MD, V. Herasevich MD, PhD, B. Pickering MD, R. Kashyap, MBBS
Multidisciplinary Epidemiology and Translational Research in Intensive Care (METRIC), Mayo Clinic, Rochester, MN

Rationale

Databases are excellent tools capturing a variety of patient data, but pulling trends is challenging. A change in hemoglobin over 24 hours or an increase in oxygen requirement may well be more significant than an isolated value. However, standard statistical software, like JMP, stores these values on separate rows, making aggregation or trending difficult. We attempted to use an iterative search strategy of a database of critical care patients to identify resolution time for patients with acute respiratory distress syndrome (ARDS).

Methods

All analysis was done with JMP statistical software. Cases of ARDS were identified using American European Consensus Conference (AECC) guidelines, corresponding to "moderate or severe" ARDS category of the New Berlin definition. ARDS resolution time was defined by the first P/F ratio >200 which is sustained >48 hours (i.e. no subsequent drops in that interval <200). All blood gas results (Pao2) and inspired oxygen (Fio2) values were obtained from the database, and combined to create P/F ratios for each lab draw interval. Subjects were sorted by medical record number and date of onset (earliest to later), such that all results were listed sequentially for each patient, where the number of distinct records for patient ranged from 2 -107 rows. A multi-iteration search was designed as shown in the figure below. Analyses were run for 1, 5, 10 and 20 iterations. This was then compared against a manual chart review of the same patients to determine the diagnostic performance of the tool.



Results

Each iteration had improved specificity, with no additional cases excluded between the 10th and 20th iteration. When compared against manual chart review, the 10 iteration model had excellent diagnostic performance at 96% sensitivity and 95% specificity.

Figure: Iterative search strategy logic. Iterations are run with N=1,2,3… until a final iteration.

Conclusions

An iterative search strategy is a viable approach to tracking variables change over time in critical care databases and has potential to speed up research by saving man power and minimizing errors related with fatigue.

Patient Factors Associated With Provider Response to a Weight Management Best Practice Alert

Annemarie Hirsch, PhD, MPH[1]; Lisa Bailey-Davis, DEd[1]; Craig Wood, MS[2]; Christopher Still, DO[3] Geisinger Center for Health Research[1], Weis Center for Research[2], Geisinger Obesity Institute[3], Danville, PA

Abstract

There has been little exploration regarding what patient factors are associated with provider acceptance of clinical decision support (CDS). We conducted a study using electronic health record (EHR) data to examine patient factors associated with referrals to weight management in response to a weight management best practice alert. BMI, age, race, gender, co-morbidities, and history of weight loss were associated with providers' response to the alert. When developing CDS tools, patient factors should be considered.

Introduction

To qualify for meaningful use (MU) incentives, hospitals and eligible providers are required to implement at least one clinical decision support (CDS) rule. Studies report that providers override up to 90 percent of CDS alerts.[1] Most of the research on providers' response to CDS tools has focused on characteristics of the alert itself, with little exploration of patient factors.[2] We evaluated what patient factors are associated with providers' response to a weight management best practice alert (BPA) in a primary care setting.

Methods

We conducted a retrospective study using EHR data to examine patient factors associated with referrals to weight management treatment in response to a weight management BPA. The alert fired when a patient with a body mass index (BMI) greater than 25kg/m^2 had an office encounter. The alert notified providers of the patient's weight status and allowed physicians to make a referral to weight management. We confined our analysis to alerts that fired during primary care encounters between March 2011 and January 2012. We used multiple logistics regression to identify patient characteristics that were associated with a referral that was ordered in response to the BPA.

Results

The BPA fired for 111,444 patients and 2004 (1.8%) had a referral to weight management. Alerts fired from 1 to 40 times for patients, for a total of 249, 508 fires. Patients had a mean age of 50.1 years; 52% were female; and 97% were white. Higher referral rates were associated with lower BMI, younger age, female gender, non-white race, and recent weight loss ($p<0.0001$ for all). In patients with BMI 25-35, those with a diagnosis of diabetes were more likely to get a referral ($p<0.0001$).

Conclusions

Patient factors were associated with how providers responded to the weight management BPA. When developing CDS tools, it is important to consider patient factors that will facilitate or inhibit provider acceptance of the tool. With a steady increase in the adoption of EHRs and the MU CDS requirement, we can expect a dramatic increase in the implementation of CDS tools, making it critical to increase our understanding of factors associated with the use of these tools.[3]

Design and Evaluation of a Glomerular Disease Ontology

Jamie S. Hirsch, MD, MSB,[1,2] Chunhua Weng, PhD[1]
[1]Department of Biomedical Informatics, Columbia University, New York;
[2]Division of Nephrology, Department of Medicine, Columbia University, New York

Abstract

Glomerular diseases have been defined and classified by their pathologic findings, but many glomerular diseases share pathologic features. The existing taxonomies for glomerular diseases contain ambiguity and can lead to errors when using these disease definitions. The Glomerular Disease Ontology (GDO) was developed to formalize the knowledge of this domain, clarifying disease entities and their relationships to etiology, pathology, clinical manifestations, laboratory data, and treatments. The current version of GDO contains 247 classes, 43 object properties, and 664 class relationships. All concepts were encoded using the Unified Medical Language System (UMLS). The GDO has the potential to provide diagnosis and treatment decision support for glomerular diseases.

Introduction

Glomerular diseases suffer from taxonomic complexities due to the conflation of kidney biopsy pathology and disease definitions. This class of diseases is often referred to by their pathologic descriptors, which yet do not imply pathophysiology or treatment. This ambiguity has negative ramifications for clinical care and research coordination. No glomerular disease-specific ontology exists, while current ontologies rely on traditional pathologic descriptors as disease entities, preserving the conflation between pathology and disease. The goal of this research is to create a domain-specific Glomerular Disease Ontology (GDO), solidifying clear disease definitions with linkages to pathologic findings, clinical presentations, and treatments, in order to facilitate clinical decision support.

Methods

Core competency questions were created to establish the ontology's scope. Domain-specific knowledge and entities were gathered from the nephrology literature and international professional society guidelines and reports. Existing related ontologies were reviewed to identify reusable disease classes. Knowledge representation was performed using Protégé version 4.3.2 in the Web Ontology Language (OWL). The ontology's class and logical consistency was evaluated with FaCT++, an automated description logic reasoner within Protégé. Expert evaluations were undertaken to assess the domain accuracy, core competency, relevance, and usefulness.

Results

The ontology currently defines 247 classes, including 105 disease-based classes, with 75 of which currently mapped to UMLS. Most non-glomerular diseases and seven glomerular diseases were imported from the Disease Ontology. Eighty-one classes have an annotated definition and 11 glomerular classes are presently defined. The "glomerular disease" class has 7 direct children and total 55 unique classes (see Figure). It currently maps most glomerular diseases to basic clinical syndromes, systemic disease associations, histologic manifestations, and clinical guideline treatments.

Figure: Hierarchical structure of glomerular diseases within the GDO

Conclusions

The GDO represents the first step toward formalizing the taxonomy of glomerular disease. Missing in the current version are rarer glomerular diseases, ultrastructural pathologic findings, clinical manifestations, laboratory findings, classification and prognostication tools, and granularity in treatment protocols. The GDO will facilitate improvements in clinician education, clinical workflow, and research organization in the field of glomerular disease.

Pictogram-based tablet application enabling patient input of emotions and behaviors

Teruyoshi Hishiki, MD, PhD[1], Hiroki Yasui, MD, PhD[2], Yoshiko Matsunaga, RN, PhD[1], Megumi Itoshima, BPh[3], Keiko Abe, RN, PhD[2], Takahiko Norose, MBA[4], Takuro Tamura[5]
[1]Toho University, Tokyo, Japan; [2]Nagoya University, Nagoya, Japan; [3]Shimokawa Pharmacy Ltd, Kumamoto, Japan; [4]Hokkaido Pharmaceutical University, Otaru, Japan; [5]LINE Co., Ltd, Tokyo, Japan

Abstract

We developed and are testing a tablet-based Web application in which patients can record their actions and emotional states as they occur. The resulting data can be shared with healthcare professionals. On the touch-screen, patients identify what to record via pictograms, which are categorized into perceived well-being, daily activities, compliance with instructions, and self-measured physical data. The application could also be used to evaluate the patient's awareness of their disease and evaluate patient–provider communication.

Introduction

At patient visits, it is useful for medical providers to gain an understanding of the patient's emotional and behavioral wellbeing over the period since the last visit, but this is difficult to obtain because of time pressure. Self-recording by the patient offers an alternative approach, and its effectiveness in chronic disease management is supported by the findings of past studies; however, adherence to this method has previously been problematic. One solution is for patients to carry a device in which they can easily record their feelings and actions at the time that they occur.

Problem to Address

We aimed to develop a touch-screen-based user interface for a portable device that would enable patients to record their feelings and actions.

The Pictogram Approach

After discussion with medical providers about the type of between-visit information that would generally be valuable, four categories were identified: (a) perceived well-being, (b) daily activities, (c) compliance with instructions, and (d) self-measured body weight and blood pressure. These categories were then expanded to a total of 12 types of information.

We developed a Web-based application for seven-inch tablet devices, on which the home page displays a panel with a pictogram for each of the 12 types of information. The user has only to touch the relevant pictogram, and in most cases this is all that is required. Some pictograms, such as "how well I am feeling" and "blood pressure" have heat map scales or slide bar scales for input. Information entered by the patients is time-stamped and stored on a server. Patients can browse their information in time order or by pictogram type, and their healthcare providers can log on to browse the same information. A healthcare provider can append a text message to the patient's input history.

Current Status

We are presently analyzing the logs of seven male patients (age range, 36–82 years; median age, 66 years) and their healthcare providers who have completed a 4-month test of the application. Two of the patients were employed, and the others were at home, while all had stable health during the test. The patients spontaneously entered 1–14 inputs per day at the beginning of the test; those who inputted frequently from the start continued this pace to the end. Pictograms for "had a meal", "feeling good", "took my medication", "measured my blood pressure", and "took a bath" were the most frequently used. Some of the healthcare providers have reported that the recorded data enable a better understanding of the patients' lifestyle.

Conclusion

The pictogram method provides a simplified input method and is a tool for identifying patients' scope of attention, which may also reflect their awareness of their disease. Factors related to the patient and to the patient–provider relationship may provide insight into the patterns of usage.

Point of entry notification of shortages using a drug auditing program

S. Paul Hmiel MD, PhD[1], Charles H Andrus, MHA [2], Kevin O'Bryan MD[2], Phillip Asaro MD[1], Feliciano Yu, MD, MSPH [1]

[1]Washington University School of Medicine, St. Louis MO; [2]St. Louis Children's Hospital, St. Louis MO

Abstract

Communicating critical drug shortages to clinicians has become a major challenge, but opportunities exist within computerized clinician order entry systems to provide appropriate alerts at the time of order entry. We added drug shortage alerting to a dose range checking and auditing system, which was previously developed as an adjunct CDS system. We added rules representing medication shortages along with degree of availability, such as unrestricted use, in shortage, and unavailable. Analysis of alerts by medication and care unit facilitated education by clinical pharmacists. Regular monitoring and user feedback identified unnecessarily repetitive alerts. Shortage status rules were subsequently adjusted to alert only once per user, per drug, per week. Medication shortage alerts require careful design, as well as providing easily updated information to be effective.

Introduction

Communication of critical drug shortages to clinicians has become an ongoing challenge for hospital pharmacy services, due to rapid changes in availability, and difficulties in identifying the appropriate clinicians[1]. The most common approach utilizes combinations of paper-based, electronic communications, and/or direct conversations, to inform the affected clinicians, as not one approach is satisfactory by itself. Computerized clinician order entry systems within the electronic medical record allow alerting at the point of entry, which would be expected to be the most efficient, with the appropriate information delivered directly to the intended ordering clinician(s), without relying on clinician memory/awareness. To be maximally effective, however, the information needs to be accurate, up to date, easily updated, with minimal alert fatigue and annoyance.

Methods

A dose range checking and auditing system was previously developed as an adjunct clinical decision support system to provide more comprehensive information to clinicians, expanding on the vendor supplied dose range checking features of the electronic medical record (EMR). Additional rules were developed to represent medication shortage and degree of availability, such as unrestricted use, in shortage, and unavailable. In addition, a dashboard was developed to monitor number and types of alerts in near real time, over varying time intervals. When the rule was applied to an order, it could result in any of 3 alert types: warning (user can proceed without a comment), soft stop (user must comment to proceed), hard stop (user cannot proceed). A recent upgrade to the EMR provides the ability to link an alert directly to an alternative medication.

Results

The Pediatric and Cardiac Intensive care units accounted for just over half of the total shortage alerts, at 31.3 % and 21.5%, respectively, of the 6110 alerts analyzed. This is reflected by the most frequently alerted agents, with 792 alerts for calcium gluconate, 457 for bumetanide (bolus or infusion), and 308 for sodium bicarbonate, with these three agents used primarily in the intensive care units. Regular monitoring of the dashboard rapidly allowed analysts to identify nuisance drug shortage alerts, which was noted especially for frequently used agents, as the frequency of alert acknowledgement rapidly decreased. Consequentially, shortage alerts went from changing practice only 21.3% of the time to 40.7% of the time. The rules for shortage status were subsequently adjusted to only alert only once per user, per drug, per week, with marked increase in clinician satisfaction (decreased annoyance).

Conclusion

Point of entry notification of drug shortages provides an additional route of communication that is focused on providers, when it is most useful, without the disadvantages of more traditional communication tools. Attention to the design and frequency of alerts is essential to user acceptance however, while ease of maintenance is essential to capture rapidly evolving supply situations. The ability to redirect clinicians for a medication in shortage to an acceptable alternative will provide additional strategies to manage shortages.

Efficient Translation of EHR Free-Text Data to Coded Data PRN

Chad M. Hodge, MS[1, 2], Trilok Prithvi, MS[1, 2], Naveen Maram, MD[1], Kathryn G. Kuttler, PhD[1], Scott P. Narus, PhD[1, 2]
[1]Intermountain Healthcare, Salt Lake City, UT; [2] University of Utah, Salt Lake City, UT

Abstract
When developing a new clinical system, Intermountain Healthcare (IH) recognized an opportunity to try new means of improving and maintaining the underlying terminology. Implementing the new process and tool has increased clinician engagement, reduced uncoded patient data, and helped meet Meaningful Use goals.

Introduction
Intermountain Healthcare (IH) works with clinicians prior to implementation of vocabularies to define, pre-coordinate, and load only the concepts and representations that are clinically useful. Post-implementation, clinicians require new content, and request synonyms for existing content, allowing for efficient searching. When terminology is incomplete, clinicians revert to adding patient data as free-text rather than as coded concepts. Current processes for handling free-text data requests are ad-hoc, and entail many months of effort. This can leave clinicians disengaged from content governance, and patient data remains uncoded and thus unavailable to decision support. To address these issues, IH developed a new terminology feedback process to engage clinicians. Novel and efficient mechanisms were developed to identify gaps and allow clinicians to interactively review and approve recommended content in the context of patient care.

Methods
During a six-month period, hospitalists, providers at seven NICUs and one STICU, and TeleHealth services had access to the new feedback tool, made available initially through our EMR's problem management module. When clinicians added a free-text problem, a structured request was automatically routed to the terminology work queue. Clinical modeling engineers (CME) then inspected the free-text term, and searched for and evaluated matches for the term in the existing dictionary to determine if the term was misspelled, an acronym, a synonym, or missing. CMEs then added the new content or created mappings between the synonym/acronym and root concept, ensuring future searches return proper results. CMEs then created a list of candidate substitutions for the clinician's free-text problem, and sent that list back to the application for review by the clinician. The next time a clinician opened the same patient's problem list, the application presented the clinician with the substitution candidates for the free-text problem (Figure 1). The original free-text was viewed alongside the list of candidates. The clinician could select a single choice to serve as the replacement for the free-text problem, or could alternatively choose to reject all provided choices with an accompanying reason. If rejected, the process was performed one more time, resulting in a new set of candidates. If the clinician chose to accept one of the newly provided coded candidates, the free-text problem was automatically replaced by the coded concept. If rejected, the problem would remain free-text.

Results
The first three days the tool was available, over 1,200 free-text requests were created during normal clinician use of the problem list. The new process handled these requests daily. The old process added new concepts to the dictionary, *if* the missing content was discovered by the CMEs. This allowed future use of the term, but left previously entered patient problems as free-text. This new approach has permitted coded content to replace the original free-text problems, with clinician interaction. In fact, free-text problems remaining on problem lists dropped from 12% using the legacy system, down to 1% using the new process.

Conclusion
Allowing clinicians to choose coded substitutes of free-text problems in the workflow has reduced free-text problems remaining on lists, engaged clinicians, and reduced turnaround time to add coded content.

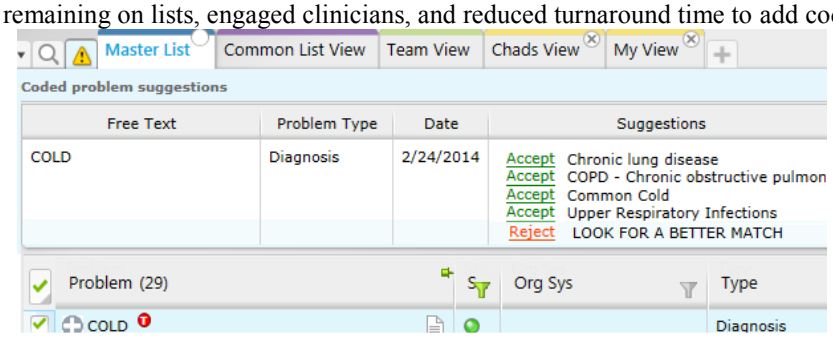

Figure 1 - Functionality in the Problem Management Module that allows a clinician to substitute a free-text problem with a coded problem, based on CME & clinical governance suggestions, or to reject candidates and request a new set of choices.

Reporting the Results of Safety-Enhanced Design Evaluations for Meaningful Use Stage 2 Certification: Are they Comparable?

Jan Horsky, PhD[1,2], Michael Swerdloff, BS[3]

[1]Brigham & Women's Hospital; [2]Harvard Medical School, [3]Partners HealthCare, Boston

Abstract

Effective, safe and routine use of HIT by clinicians is predicated on the availability of well-designed systems that have excellent usability characteristics and can be integrated into common clinical workflows The ONC has required, for the first time, that institutions and vendors developing EHRs submit results of summative usability evaluations as part of their application for Meaningful Use Stage 2 certification. The intent was to let developers show evidence of usability of their product so consumers could make informed purchase decisions. The expected content of each usability report was specified by the NIST in the Common Industry Format Template. However, a review of published test protocols shows wide variations in methods, content and study size. It may prove to be difficult for consumers to make effective comparisons across systems and make informed purchase decisions.

Description

Effective use of health information technology (HIT) and continuing progress in its adoption by clinicians are the objectives of national policy initiatives in many countries.[1] The rationale driving the implementation of electronic health record systems (EHR) and decision support is their potential for monitoring and improvement of care quality and the safety of patients. There is an emerging consensus among leaders in the industry, academia and government that a sustained positive effect of HIT can only be achieved by using systems that are specifically designed for the complex healthcare environment and that provide cognitive support, have high standards of usability, advanced interface design and are well integrated into clinical workflows.

The Office of the National Coordinator for HIT (ONC) has underscored the significance of high-quality design as a pre-requisite for high performance and safety of information systems in Stage 2 of its Meaningful Use Criteria for 2014. It has added a requirement to report the results of a summative usability evaluation and an attestation that development was done in accordance with a user-centered design process in order to receive certification and financial incentives. The intent was to help vendors and developers at academic and public institutions demonstrate evidence of EHR usability in a format that allows both independent evaluation and comparison across products.[2] The test results are made public on the ONC website to allow consumers and procurers at large institutions to review and assess basic usability characteristics of systems they may consider purchasing. Developers may also use the insights and lessons learned from the test process to further refine the design of their systems and to focus on problem areas that may not have been previously identified.

The format and required content of result reports was specified by a common industry format template[3] but methods and the extent of evaluations (sample size, scenario complexity) varied by system and institution. For example, the number of clinicians participating in observational studies varied from 3 to 30 (as of June, 2014). Test settings content of scenarios and the interpretation of results such as path deviations, type and severity of errors and task success or failure criteria almost certainly varied from one report to another and some criteria were not described in reports at all. The evaluators were sometimes usability professionals hired by vendors to run the study or experts already working for the institution but often just information system developers whose appropriate training or experience in usability evaluation was not reported. A comparison of reports published on the ONC Meaningful Use site shows wide variations in the number of clinicians tested, methods used to derive the results and completeness. The intended comparability of results across systems may be difficult to achieve.

Abstract

Clinical information is fragmented across many different organizations and computer systems. To view complete, longitudinal medical records for a patient, clinical systems are starting to routinely, electronically request information from various sources in the form of a Continuity of Care Document (CCD). Given the heterogeneity and fragmentation of data across sources, systems are likely to receive multiple CCDs for a single patient. Current tools for viewing CCDs make it cumbersome for providers to explore different CCDs to find a specific data which can be duplicated or even conflicted. We have developed a modular approach for integrating and de-duplicating multiple CCDs into one consolidated document. Our system is designed to support nationwide and regional health information exchange efforts to support integration of standard clinical documents into clinical information systems for presentation to clinicians.

Introduction

The Continuity of Care Document (CCD) is an electronic document exchange standard for sharing patients' health information summary between providers and organizations which is required under Meaningful Use criteria. Given the fragmented and heterogeneous nature of clinical data, requests for complete medical records results in multiple CCDs from a variety of sources, however, care providers prefer to review consolidated information that represents a single, comprehensive picture of a patient's medical history and current condition, rather than multiple CCD documents that may include duplicate or conflicting information.

Methods

We designed a modular, open source system that aims to consolidate and de-duplicate received CCDs. The key component is the CCD Consolidation Engine, which executes a set of rules against a list of CCDs to produce a single, clinically useful CCD. Four types of rules are executed: 1) Pre-Format Rules examine incoming CCDs and inspect them for quality; 2) Primary Rules ensure the program returns valid information to the user; 3) De-duplication Rules merge, de-duplicate and handle conflicting information in the list of CCDs; and 4) Post-Format rules clean up the returned, consolidated and de-duplicated CCD. The system further audits all actions performed to comply with federal regulations. We further developed an application programming interface (API) to enable remote interaction through web services. The system is developed using the C# language and we used Microsoft .NET libraries to manipulate XML documents. Audit data is retained in a NOSQL database, such a Hadoop.

Results

A prototype was developed for a local health software competition, for which it took top honors. The prototype currently executes consolidation and deduplication rules against a de-identified reference dataset at a rate of approximately .009 to .03 seconds per rule depending on complexity. Evaluation of precision and recall using a larger dataset from an operational health information exchange is currently underway.

Conclusion

Given that meaningful use regulations and many HIE organizations are less than three years old, there do not yet exist a plethora of proven solutions for consolidating CCDs. Consolidation of CCDs, however, is challenging and requires processes that can interpret, merge, de-duplicate, and resolve conflicts across complex documents involving complex data types. Accuracy of the de-duplication and consolidation greatly depends on the logic used in the Consolidation Engine. The benefit of the audit model chosen for this project is that it can be used to analyze the logic and clinical usefulness of the output. Health informatics researchers and scientists will be able to improve the algorithms and methodologies used in the rule logic over time increasing the clinical usefulness of the CCD.

Evaluation of SNOMED CT Content Coverage for a Decision Support System

Rachael Howe BSN, RN, Tosh Kartchner RN, Kristen Humpherys BSN, RN, Tiffany Harman RN, Susan Matney MSN, RN, PhD (c), FAAN, Senthil K. Nachimuthu MD PhD
3M Health Information Systems, Inc., Murray, Utah

Introduction

The 3M Healthcare Data Dictionary (HDD) was used to standardize the clinical data used by a decision support system (DSS) which was used for clinical quality assurance and reimbursement. The HDD is a vocabulary server that stores standard and local terminologies. The goal of this project was to map the DSS concepts to Systemized Nomenclature of Medicine Clinical Terms (SNOMED CT) in order to analyze the EHR data. The DSS data included nine disease processes: chronic obstructive lung disease, pneumonia, acute coronary syndrome, heart failure, etc.

Methods

There were 3 phases of this project: analysis of content to identify patterns, terminology mapping, and evaluation. Analysis consisted of reviewing the DSS data, identifying the concept models or patterns within the data, and creating the rules necessary to map to SNOMED CT. 'Rule concepts' or 'questions' are necessary for clinical decision support, and linkage to the standards mapping and were made in conjunction with the DSS' needs and knowledge. For example the rule might state, 'postictal state > 10 min', and is used to determine that the patient has been postictal for a certain duration of time. The mapping phase consisted of linking all the DSS concepts in the HDD to represent its hierarchy, and then linking all the clinical concepts in the DSS terminology to SNOMED CT concepts within the HDD. The evaluation phase consisted of looking at the SNOMED CT concepts used in mapping to determine difficulties that could arise when the DSS implements the mapping in their system.

Results

Analysis resulted in the creation of base concepts within the concept model. Base concepts are considered 'domains' that were used for grouping the answer choices. The base concepts were created based on the DSS' clinical knowledge. The mapping phase consisted of adding all local representations and relationships into the HDD, and then linking these and the base concepts to the appropriate SNOMED CT concepts. Once all concepts were mapped both the SNOMED CT concepts and our mappings were evaluated for consistency and accuracy. Inconsistencies were found in SNOMED CT concept coverage causing difficulties in implementing the DSS' rule concepts and some examples are illustrated in **Table 1**.

Table 1 Inconsistencies in SNOMED CT concept coverage

DSS Concept	Patient History SNOMED CT Concept	Family History SNOMED CT Concept	Issue
History of back pain	1. History of (contextual qualifier) -392521001 2. Backache (finding) -161891005	Family history of backache (situation)- 429976008	There is a 'family history of backpain' but not a 'patient history of back pain'
History of GI bleed	History of - gastrointestinal bleed (situation) - 275551007	1. Family history with explicit context (situation) -57177007 2. Gastrointestinal hemorrhage (disorder)- 74474003	There is 'patient history' but not 'family history'
History of stroke	History of - cerebrovascular accident (situation) - 275526006		Pre coordinated found for this but not for 'history of dysphagia' as shown above

Conclusion

Results demonstrated inconsistencies in SNOMED CT concept coverage. Types of inconsistencies included pre/post coordination of past history, family history, contraindications, negation, and normal/abnormal results. This caused the rules utilized in the DSS to be quite complex. There needs to be consistency in SNOMED CT concept coverage for systems to implement in a consistent way. Otherwise, users will not know when to look for pre- versus post-coordinated terms. SNOMED CT is a clinical terminology standard that could be utilized in EHRs and clinical systems, however for this to be achieved further work in the consistency of concept coverage is needed.

Automated notification of primary care providers upon patient admission: pilot results from a randomized controlled trial

Gregory W. Hruby MA[1], Hojjat Salmasian MD[1], Rimma Pivovarov[1] MA, Daniel G. Fort MPH [1], Nancy M. Chang MD[2], David K. Vawdrey PhD[1]
[1]Department of Biomedical Informatics; [2]Department of Medicine
Columbia University Medical Center, New York, NY

Background

Healthcare reform in the U.S. demands greater coordination and continuity across care settings. Building on our previous work to automate the process of identifying patients' primary care providers (PCPs) in an electronic health record, we implemented an electronic notification system to alert PCPs when their patients were admitted to our hospital. In preparation for a randomized controlled trial to evaluate the impact of the system, we conducted a pilot study involving attending PCPs caring for patients in an ambulatory internal medicine clinic at our academic medical center. This work reports the results of the pilot evaluation.

Methods

The automatic PCP notification system was developed in collaboration with clinical, informatics, and information technology groups at New York-Presbyterian Hospital. Using the Arden Syntax, a medical logic module (MLM) was created that sent a secure health message (SHM) to a PCP when one of his/her patients visited the emergency department (ED) or was admitted to our hospital. From November 2, 2013 to January 1, 2014, we measured baseline 30-day post-discharge follow-up visit to the clinic as well as 30-day hospital readmission rates. From January 15 to March 1, 2014, we measured the impact of SHM notifications using 30-day post-discharge follow-up visit to the clinic as our primary outcome. We obtained consent from 16 attending physicians and randomized them to two study groups of n=8: the intervention group received SHM notifications, while the control group did not. In addition to our primary outcome, we calculated 30-day hospital readmission rates and conducted a survey that was issued to PCPs within 24 hours after each patient admission or ED visit. The survey was designed to verify the accuracy of the PCP identification mechanism, assess the PCP's awareness of his/her patient's ED or hospital encounter, and evaluate the PCP's perception of the usefulness of the SHM notification.

Results

Survey. The overall survey response rate was 66.3% (77/116). The survey indicated that our identification mechanism was still performing as intended, with an accuracy rate of 92.2% (71/77). PCP awareness of the admission or ED event for the study group and control group was 62.8% (27/43) and 21.4% (6/28), respectively ($p=0.043$). In the intervention group, physicians who were initially notified through the SHM, 88.9% reported it useful.

Clinical Outcomes. The baseline rate for 30-day readmission and 30-day follow-up visit in clinic was 20% (8/40) and 94.6% (88/93) respectively. The 30-day readmission rate for the intervention and control group was 30.4% (7/23) and 26.6% (4/15) respectively, ($p>0.999$). The 30-day follow-up visit in clinic rate for the intervention group and control group was 80.0% (56/70) and 73.9% (34/46), respectively ($p=0.498$).

Conclusion

We observed a significant increase in primary care providers' awareness of their patients' ED visits or hospital admissions in the group that received SHM notifications. We observed a 6% absolute increase in the rate of 30-day follow-up visit to the clinic from the control group compared to the intervention group, although it was not statistically significant. Furthermore, we confirmed that the automated PCP identification mechanism we previously studied has remained accurate over time.

Development and Evaluation of a Mobile Medication Patient Symptom Support (M^2-PASS) System to Strengthen Cancer Patients' Transition from Hospital to Home

Angela Hu, BA[1], , Kenneth Patrick, MD[1], J. Robert Beck, MD[1], DeLinda Pendleton, RN, MSN, CPHQ[1], Mike Korostelev, MSECE[2], Ning Gong, MSECE[2], Li Bai, PhD[2] Kuang-Yi Wen, PhD[1]

[1]Fox Chase Cancer Center, Philadelphia, PA; [2]Temple University, Philadelphia, PA

Abstract

During the transition from hospital to home, cancer patients are particularly vulnerable to adverse drug events, a known driver for hospital readmission rates. Text-based mobile health interventions represent a highly customizable and low-cost platform that can be integrated with telephonic nurse follow-ups to enhance standard care delivery. This study evaluates the feasibility of an integrated 2-week patient medication and symptom management intervention (M2-PASS) delivered via short message services (SMS) and telephonic nurse follow-ups.

Introduction

Transitional care refers to a set of actions which ensure the coordination and continuity of health care as patients transfer between different locations or different levels of care within the same location. Cancer patients are particularly vulnerable to adverse drug events (ADEs), a known driver for hospital readmission rates, during their transition from hospital to home. Improving the quality of transitional care and discharge planning is critical for reducing high hospital readmissions rates and will require multidisciplinary cooperation to develop novel methods for addressing medication management, symptom monitoring, and patient education. Text-based mobile health (mHealth) interventions represent a highly customizable and low-cost platform that can be integrated with telephonic nurse follow-ups to enhance standard care delivery and engage patients with calls to action. This study evaluates the feasibility of an integrated 2-week patient medication and symptom management intervention (M^2-PASS) delivered via short message services (SMS) and telephonic nurse follow-ups.

Methods

Content development was overseen by an expert group who advised on common drug side-effects, patient empowerment strategies, and health literacy. Information technology systems were developed iteratively on the front and back-end to support secure, automatic delivery and receipt of SMS messages on a user-friendly interface. This study will recruit N = 100 newly discharged adult cancer patients to the 2-week intervention. Participants will receive medication reminder texts the morning after their discharge, be prompted to respond confirming receipt of medications reminder texts, complete a nurse follow-up call two days after discharge, and receive twice daily symptom management texts. Feasibility will be determined by participants' confirmed receipt of medication reminder texts and satisfaction with the intervention.

Results

This study will be completed in summer 2014 and data will be available for conference presentation. We will evaluate user participation based on confirmed receipt of medication texts and completion of nurse follow-up calls. Changes in medication adherence, symptom severity and distress, self-efficacy for symptom management, and health-related quality of life will be assessed between baseline and post-intervention assessment. We will also document the frequencies of readmission rate and evaluate their potential causes. Post-intervention patient interviews will be conducted to determine user satisfaction and quantitatively analyzed to modify or improve the intervention in terms of message frequency, content, and intervention duration.

Discussion

Medication adherence is a critical component of transitional care. This study is innovative in its integration of text-based mobile health solutions and telephonic nurse follow-up calls to enhance the delivery of transitional care in adult cancer patients. Text-based symptom management also serves as a low-burden method of improving patient self-efficacy and confidence in their own care. This integrated health delivery system offers a novel approach to reducing health care costs related to hospital readmissions.

Usability of a Novel Wearable Camera System to Inform Tailored Intervention with Dementia Family Caregivers

Lu Hu, MSN[1], Jennifer Lingler, CRNP, PhD[1], Julie Klinger, MA[1], Laurel Mecca, MA[1], Grace Campbell, PhD, MSW[1], Amanda Hunsaker, LSW, MPH[1], Sally Hostein, BA[1], Bernardo Pires, PhD[2], Martial Hebert, PhD[2], Richard Schulz, PhD[1], Judith Matthews, PhD, MPH[1]
[1]Univ. of Pittsburgh, Pittsburgh, PA, USA; [2]Carnegie Mellon Univ., Pittsburgh, PA, USA

Abstract: *Clinicians usually rely on family caregivers' (CGs) reports, which may be selective or biased by imperfect recall, to understand challenges faced at home. Our multidisciplinary team designed a wearable camera system to capture daily interaction between persons with dementia (PWDs) and their CGs. Clips derived from the video data provided a springboard for discussing strategies to deal with dementia. Preliminary findings suggest that our system facilitates tailored interventions which may increase CG confidence and reduce burden.*

Introduction: Family CGs of PWDs often suffer distress from dementia-related difficult behaviors exhibited at home. However, primary care providers have limited opportunity to observe dyadic interaction during brief clinical encounters, and they have no objective method for assessing these caregiving concerns *in situ* to inform their plan of care. We have harnessed advances in mobile computing and camera technology to develop such an objective method, and in this presentation we report preliminary findings regarding the usability of our system with the first five dyads.

Methods: We visited community-residing PWDs and their CGs to obtain their consent and collect baseline demographic, health, and functional status information; to learn CGs' attitudes toward technology; and to assess CGs' perceptions of caregiving burden (Zarit Burden Interview) and self-efficacy. CGs were shown how to use our system, which includes a tiny camera attached to overglasses and a vest that holds the battery and electronics. They were asked to wear the system for as many waking hours as desired at home over two 3- to 7-day periods. CGs received a daily call to remind them to change the battery and SD card and to insert the SD card into a USB port on a laptop left in the home, to enable remote uploading of their camera data. Video clips derived from the first wear period plus CG reports of difficult behaviors exhibited by PWDs formed the basis for an intervention that included suggestions of individualized strategies that the CG could implement. These suggestions were made during a home visit by our interventionist, which was followed by three booster calls to reinforce the intervention. Usability was assessed immediately post-intervention, after the second wear period. Measures of CG burden and self-efficacy were repeated 3 months later.

Results: Five dyads (4 Caucasian, 1 African-American) have completed this protocol to date. Two caregivers were husbands and three were daughters, with a mean age of 65.2±19.4 years. All PWDs were female (M=79.8±5.2 years), and their mean Mini-Mental State Examination score was 18.4±11.7. All study participants had at least a high school education (CGs: 15.6±0.9; PWDs: 14±2.0 years). A total of 711 video clips was generated over an average of 13 days per dyad, with wear times of up to 8.5 hours per day beginning as early as 7:00 AM and ending as late as 1:00 AM the next day. Tailored interventions included suggestions to create distraction, simplify instructions, anticipate threats to safety, accept or increase respite from other family members or community agencies, and pre-medicate with short-acting analgesics to prevent or reduce activity-induced pain during bathing or exercise. After the second wear period CGs rated statements about our system from 1 (not at all accurate) to 10 (extremely accurate) and reported it to be fairly easy to learn to use (M=9.2±1.3), with little concern about invasion of privacy (M=2.4±1.9) or system flimsiness (M=2.8±4.0). They reported experiencing minimal nervousness (M=1.6±0.9), anxiety (M=2.2±2.7), embarrassment (M=2.8±4.0), or confusion (M=3.4±3.3) related to using it. In contrast, CGs did not regard the system as particularly attractive (M=3.2±3.2), capable of making life easier (M=2.8±2.0), or helpful in achieving important goals (M=2.8±1.5). Their views were neutral regarding the system's portability (M=5.0±4.2) and potential benefit vs. cost (M=4.2±3.3). Compared to baseline, CGs' self-efficacy at 3 months post-intervention increased from 58.3 to 66.1 and their burden decreased from 27.4 to 24.3. Positive comments included "Had my doctor had a copy of that tape [showing] her constricting [from severe contractures] like that for the past one or two years…[her pain] would have been addressed much sooner" and "Maybe a one or two-day video…should be supplied…to the doctor, so he can see for himself what's going on."

Conclusion: CGs are willing to wear a camera system to capture daily interaction with their PWDs, providing evidence to inform tailored intervention which may, in turn, increase CGs' confidence and reduce their burden.

Integrating a Diagnostic Decision Support Tool into an Electronic Health Record and Relevant Clinical Workflows through Standards-Based Exchange

Nathan C. Hulse, PhD[1,2], Grant M. Wood[1], Siew Lam, MD,MS[1], Michael Segal MD,PhD[3]
[1]Intermountain Healthcare, Salt Lake City, UT; [2]Department of Biomedical Informatics, University of Utah, Salt Lake City, UT; [3] SimulConsult Inc., Brookline, MA

Abstract

Diagnostic decision support systems (DDSS) have a rich history that dates back to very early experiments in medical informatics. Yet the overall uptake and usage of these types of tools in a clinical setting has been characterized as lower than expected. In an effort to make better use of a DDSS that specializes in rare diseases and genetic diseases, we are integrating the software more tightly into clinical workflows within our electronic medical record, making it available as an integrated part of our clinical notes module. The integration uses relevant HL7 standards, including the Context Aware Knowledge Retrieval Application (Infobutton) standard and the Clinical Document Architecture (CDA), to facilitate communication of the data in and out of the DDSS. In addition, the system integration assists the physicians in creating clinical notes, capturing the information entered into the software and returning to the medical record recommendations and inputs ranked by pertinence for the physician to review. We anticipate that the integration of the resource will make it easier for physicians to use the software and benefit not only from the diagnostic aid, but also in the creation of necessary documentation required for care and even the justification for the ordering of specific genetic tests.

Introduction/ Background

Diagnostic error has been highlighted as an important issue in medicine, and diagnostic decision support systems (DDSS) hold great potential for addressing this issue. Yet their overall uptake in regular practice has been described as far lower than would be expected[1]. Researchers have explored the reasons behind this and have characterized several themes that have led to lower uptake of DDSS in practice. Some of the primary reasons include 1) that the average physician does not feel the need to seek out DDSS in routine care 2) time pressures, in part due to double data entry and 3) perception that the likelihood of the DDSS suggesting something that would significantly alter their treatment for the patient is low.

Methods

In 2013, Intermountain Healthcare, Geisinger Health System and SimulConsult were awarded an SBIR grant in which we jointly proposed a tighter integration between the medical record and the DDSS offered by SimulConsult. In this effort we have attempted to address some of the underlying reasons for lower DDSS usage mentioned above by making the tool available and connected within clinical workflows. At Intermountain, we have met with a group of geneticists and neurologists (likely candidates for using the tool) and have identified some key functions for addressing workflow. These include 1) Integration with the clinical notes module, a typical 'kick-off point' for the use of this type of DDSS 2) standards-based data input into the tool, preventing the need for having users re-enter data that is already present in the medical record and 3) the ability for the SimulConsult tool to pass back template clinical notes and a session summary report, using standards-based exchange. Users will also be able to review other physicians' interactions with the tool, as well as re-launch a previous session with all previous findings intact.

Results/Discussion

In this poster, we will present results from our integration efforts, including details about our approach and design, overall usage data, user feedback, and how relevant HL7 standards for data exchange fit into the effort.

Conclusion

We feel that our approach provides value for our users by lowering barriers to usage, including improved workflow consideration, less need for duplicate data entry, and greater practical value in assisting users with necessary documentation. Aspects of our approach would likely benefit other DDSS implementations in achieving greater use.

Evaluating the size of deceased patient EHR research data sets: A multi-year trend analysis

Vojtech Huser MD, PhD[1], Aaron Miller PhD[2], David K. Vawdrey PhD[3]
[1]NIH Clinical Center, Bethesda, MD; [2]Marshfield Clinic Research Foundation, Marshfield, WI; [3]Columbia University Department of Biomedical Informatics, New York, NY

Abstract

In recent years there has been an increased interest in streamlining research access to Electronic Health Record (EHR) data. In addition to deidentification and rending EHR data free of Protected Health Information (PHI), records of deceased patients can be also used in research. Decedent research clause within Health Insurance Portability Act (HIPAA) regulation enable such research use without the requirement of full IRB review or informed consent.[1] To investigate the value of deceased subject Integrated Data Repository (dsIDR), we analyzed the size of dsIDR at various timepoints. We demonstrate on an IDR of a large integrated delivery network (Marshfield Clinic), that an IDR will contain more deceased patients than living patients in 2056 by projecting current data trends into the future. A confirmatory assessment at IDR of Columbia University Medical Center showed a similar trend.

Background and Methods: The Marshfield clinic (MC) health system consists of 57 centers and employs over 800 physicians and more than 3,000 nurses. Since 1985, MC has been a pioneer in the use of electronic health record with a home-grown EHR system called CattailsMD. It represents a large integrated delivery network (IDN) and captures a large portion of the medical care in central and northern Wisconsin. MC's integrated data repository is hence a suitable model data repository to study the size of deceased patient population in time. We tested the hypothesis that at some point in the future, the number of decedents stored in the RDW will be larger than the number of extant patients in the warehouse. Due to gradual adoption of EHR, the current coverage of the local population by any given warehouse (of an integrated delivery network) should grow in time and the warehouse will eventually contain data on all long-term residents and deceased long-term residents in a geographical area of an IDN. We analyzed the size of dsIDR at various times (December 31st of each year from 2002–2013). To avoid bias by patients that move to an area temporarily and do not receive their long-term care within the IDN, we only included patients with at least a 15–year time span between their first and last lab test (L15, "long-term" patients) as a proxy for long term residents.

Preliminary Results: The Table shows the computed *dsR ratio* for years 2002-2013 as a fraction of deceased patients over the total patients (only L15 patients are included in the table).

Discussion and Conclusion: In the study period, we see a growing number of living L15 patients. This reflects a growing coverage of IDR of the local population. We expect that this number will approximate to the number of care-seeking long-term residents in the covered geographical area (reduced by the IDN market share proportion). The dsR column indicates growing ratio and increase by 0.89 percentage points per year. Extrapolating this trend into the future we expect MC's IDR to contain more deceased patients in 2056. Although the results assume a dominant role a given IDN in a geographical area, the results apply clinical settings with multiple provider networks, if the patients maintain their provider preference over time. To confirm our findings, we computed similar measures for IDR at Columbia University Medical Center (CUMC) in New York City for years 2005–2013. CUMC data showed a similar rising trend in dsR, from 3.67% in 2005 to 8.97% in 2013. Differences in the dsR rate between the two institutions may be related to differences in populations and variation in the accuracy of death records in the institutional clinical data warehouses.

Table: dsR ratio data for Marshfield Clinic.

Year	Total	Deceased	Living	dsR
2002	25,263	563	24,700	2.23
2003	37,921	1,356	36,565	3.58
2004	48,480	2,210	46,270	4.56
2005	57,764	3,333	54,431	5.77
2006	67,159	4,516	62,643	6.72
2007	76,375	5,843	70,532	7.65
2008	85,469	7,253	78,216	8.49
2009	95,780	8,846	86,934	9.23
2010	107,032	10,714	96,318	10.01
2011	119,696	12,727	106,969	10.63
2012	131,608	14,884	116,724	11.31

Encoding Performance Measures For Automated Quality Assessment

Tammy S. Hwang, [1]Susana B. Martins, MD MSc,[1] Samson W. Tu, MS [1,2], Dan Y. Wang, PhD[1], Paul Heidenreich, MD[1, 2] Mary K. Goldstein, MD, MS[1, 2]
[1]VA Palo Alto Health Care System, Palo Alto, CA; [2]Stanford University, Stanford, CA

Abstract

Performance measures evaluate the proportion of relevant patients for whom appropriate medical care was provided. Performance measures for heart failure (HF) are complex to evaluate, requiring multiple sources of clinical data, such as diagnoses, procedures, labs, and medications. Currently, most health care systems use human reviewers to do manual review of patient data to report quality measures for HF. We created an automated HF performance measurement system utilizing a Protégé knowledge base and EON software as an execution engine.

Introduction

National Quality Forum (NQF) reviews and endorses standardized healthcare performance measures (PMs), also called quality measures, used by many hospitals and healthcare systems to monitor and improve care. Manual chart abstraction for data to compute PMs is labor-intensive and hence costly; automated systems could decrease the time of professional staff in chart review to reserve professional expertise for cases requiring human judgment. In this project, we aimed to develop a pipeline for automated performance measurement of heart failure (HF) management.

Methods

Subject matter experts identified high priority HF PMs endorsed by NQF. We focused on measures pertaining to Angiotensin-Converting Enzyme inhibitors/Angiotensin Receptor Blocker therapy and beta-blocker therapy in HF patients (NQF 0081 and 0083). The automated pipeline is designed to identify (1) whether a patient is eligible for a recommendation during a PM's measurement period (denominator) and (2) whether the patient's medical regimen during the measurement period adhered to the recommendation (numerator). The process becomes complex when introducing denominator exclusions, which may be medical-, system- and/or patient related-reasons. Where the target PM listed a condition without fully specifying it, we expanded our knowledge sources to related PMs (e.g., NQF 0615) for specifics. We encoded the numerator, denominator, and exclusion criteria in a Protégé knowledge base (KB). For each PM, we could specify multiple methods for defining inclusion or exclusion criterion, for example: for the exclusion criterion "hyperkalemia," patients who had an ICD9 code for hyperkalemia as an inpatient admission diagnosis (from inpatient encounter domain) or who had a potassium greater than 5.0 (from the LabChem data domain using LOINC) would be excluded. For each inclusion or exclusion criteria, we defined the time period to search for the data (e.g. performance measurement period), decision rules for missing data, appropriate data domains to search (e.g. ICD9 codes, CPT codes, allergies, or labs), and appropriate data ranges when applicable (e.g. creatinine > 2.5). We adapted the EON execution engine, previously developed to provide guideline-based CDS, to process and evaluate the criteria encoded in the Protégé KB, and we then stored the results in a SQL server database. The output is an automated PM report of proportion of eligible cases, computed as the numerator/denominator as well as detailed information about patients meeting exclusion criteria.

Results

We encoded 6 inclusion criteria and 34 exclusion criteria. Preliminary evaluation, with a convenience sample of 20 outpatient and 17 inpatient cases, compared human reference standard with system output; the system made the correct conclusions in all cases regarding eligibility for the PM, lists of exclusion criteria, and percent attained on the PM for those eligible.

Conclusion

Our results suggest that our HF PM system automates performance measurement of HF management taking account of complex criteria and multiple domains of structured patient data. This could allow for real time performance measure and support interventions to improve health care outcomes by quickly identifying patients who would benefit from specific therapeutic regimens. Further validation and refinement with a larger dataset is needed.

Smart infusion pump limit violations and high alert medications: the role of the Single Step Titration Error Prevention system

Authors: Cary Ikemoto RPh; Tim Hoh RPh; Idal Beer, MD, MBA, MPH. Fluid Systems Therapeutic Area, Baxter Healthcare Corporation, Deerfield, IL. cary_ikemoto@baxter.com

Problem: Smart pump technology is intended to reduce programming errors with Dose Error Reduction Software (DERS), which triggers alerts when programmed values exceed facility-defined upper or lower dosing limits. Titration programming, where a significant incremental dose or rate change does not exceed soft or hard dosing limits is not intercepted by traditional DERS. High alert medications, which bear a heightened risk of patient harm when used in error, are frequently titrated. Titration of high alert medications may cause harm, even within conventional soft dosing limits. **Purpose:** An additional drug limit alert related to percent titration is available from at least one device manufacturer. It captures titration programming entries that exceed a predefined rate change percentage (both high and low). The purpose of this investigation is to review smart infusion pump data to understand the frequency of titrations and related alerts which may demonstrate the significance of having an extra safety check within the soft limits for high-alert medications. **Methods:** Blinded infusion pump data from two (2) U.S. IDNs were analyzed: IDN 1: average of 2198 pump channels, 9 months of data (2013); IDN 2: average of 692 pump channels, 7 months of data (2012). Initial programming and titrations were analyzed for the following high alert medications: Amiodarone, Dobutamine, Dopamine, Epinephrine, Esmolol, Fentanyl, Heparin, and Norepinephrine. The SIGMA Spectrum Infusion system, used for this analysis, includes a Single Step Titration Error Prevention system in addition to traditional DERS. The Single Step Titration Error Prevention system captures programming events when the incremental dose change exceeds the facility defined percentage (%) increase or decrease. **Results:** There were 19,711 programming events, 43% related to titration programming (Figure 1). Of the titration programming, soft dosing limit violations accounted for 44% of alerts, hard limit violations accounted for 10% of alerts, 43% of alerts were titration limit violations and 3% were a combination of soft limit and titration limit alerts (Figure 2). **Conclusion**: Titrating high alert medications, even with soft and/or hard dosing limits can potentially cause patient harm. The Single Step Tritation Error Prevention System prompted clinician review, confirmation, and intercepted 3646 potential patient safety events in this analysis.

Problem Addressed

The morning report session can be anxiety provoking in many learners as they are often put on the spot (pimped) during the session to extract their understanding of the case. This often leads to learners either avoiding the interaction, or not submitting their excellent contributions for fear of public humiliation.

Informatics System Solution

Morning report has been a staple of medical education dating back to Sir William Osler at John Hopkins in the early 20th century. The style of morning report differs quite significantly around the country with some academic centers using cases admitted from the previous night, while others utilize interesting cases discovered during the course of a month's clinical rotation. Almost universally the case is run by a "facilitator" (faculty member or chief resident) while the "learners" consist of medical students, residents, and sometimes fellows.

We hypothesized that "learners" would prefer a model that allowed a crowdsourcing of learning with the ability to share their knowledge without risk of public humiliation. After discussion with key stakeholders within the medical education system a framework was devised in order to support a dynamic, mobile enabled system that allowed direct interaction with the case in an anonymous form.

The system (From the Case Files) was developed to allow a "facilitator" to have a mobile device that enables them to directly place information both on a projected screen, and on the "learners" mobile device (Figure 1). This information could then be utilized to dynamically generate a differential diagnosis using SNOMED-CT concepts (Figure 2) and orders using LOINC concepts (Figure 3). Differential diagnosis generation and order entry are crowdsourced to allow information generated by other learners to be anonymously added for ranking by an individual learner.

Additional features such as Medicare based reimbursement costs, laboratory based result questioning, and group ranked differential (probable, possible, and unlikely) were all involved in the system creation. A demo video of the participants' interaction during a case presentation is available at https://www.youtube.com/watch?v=pqIvO5nGP5U.

The system is undergoing further development to provide individualized feedback to learners and facilitators while adding additional features of gamification. It is being beta tested at a single large academic institution for morning report with plans to release for general use.

A Systematic Review of eHealth Interventions to Improve Health Literacy

Robin J. Jacobs, PhD, MSW, MS; Jennie Q. Lou, MD, MSc; Raymond L. Ownby, M.D., Ph.D.; Joshua Caballero, Pharm.D., B.C.P.P.
Nova Southeastern University, Fort Lauderdale, FL

Understanding patients' health literacy (HL) in relation to behavioral risk factors is an important goal in the prevention and management of chronic diseases. One possible approach to addressing low HL is to create eHealth interventions that are acceptable, easily deployed, and cost-effective. Currently, few studies exist that systematically reviewed technology-based HL interventions. The purpose this study was to identify and summarize eHealth technologies employed to improve HL; discuss effectiveness of eHealth applications to improve HL based on reports of attributes; and identify the gaps in knowledge in eHealth applications to improve HL to guide future research.

A review of the current state of the science regarding types of eHealth technology for health literacy interventions was conducted. The study selection criteria flowed directly from the review question (i.e., What are the current eHealth interventions to improve health literacy?) and were specified a priori. Interventions had to include at least one eHealth delivery component (e.g., touchscreen computer, handheld electronic device, Internet delivered and one measure of [or components related to] health literacy to promote positive change in lifestyle behaviors for improved health outcomes). Abstracts were searched in a systematic fashion using the keyword search "health literacy" AND "health information technology" AND "eHealth" OR "e-Health" from scientific databases to assess the presence of eHealth applications targeting HL. A search of 16 databases (e.g., Biomedical Reference Collection, Health Technology Assessments, MEDLINE) yielded 466 abstracts, of which 12 were included in this review.

Compared to control interventions, the interventions using technology reported significant outcomes or showed promise for future positive outcomes regarding HL in a variety of settings, for different diseases, and with diverse populations. Understanding and measuring patients' health literacy in relation to behavioral risk factors is an important goal in the prevention, detection, and management of chronic diseases. A concern is the fact that overall health literacy rates are poor and even poorer for individuals from lower socioeconomic and/or ethnic minority backgrounds. Implementation of eHealth and health information technologies is being considered as an effective alternative in addressing current concerns about the health status and quality and safety of the U.S. health care consumer population. Thus it is imperative that we ascertain best practices for delivering health literacy interventions using information technology that is accessible and cost-effective. This review has indicated that it is possible to deliver eHealth interventions specifically designed to improve health literacy skills for people with different health conditions and risk factors. There is also evidence to suggest eHealth interventions may be more effective particularly for individuals with very low literacy. What remains less clear is the extent to which patients with will feel comfortable using a computer or handheld electronic device or will have access interactive eHealth programs using these modalities. It is also likely that understanding how the healthcare system works in addition to eHealth interventions is an important aspect of health literacy. Before eHealth interventions can be hailed as a behavior change intervention of the future, the effective components and mechanisms need to be identified, rigorously tested, and its cost-effectiveness established in different contexts.

An Analysis of Mayo Clinic Search Query Logs for Cardiovascular Diseases

Ashutosh Jadhav, MS[1], Amit Sheth, PhD[1], Jyotishman Pathak, PhD[2]
[1]Knoesis Center, Wright State University, Dayton, OH; [2]Mayo Clinic, Rochester, MN

Abstract

Increasingly, individuals are taking an active role in learning and managing their health by leveraging online resources. Understanding online health information searching behavior can help us to study what health topics users search for and how search queries are formulated. In this work, we analyzed 10 million cardiovascular disease (CVD) related search queries from MayoClinic.com. We performed a semantic analysis on the queries using UMLS MetaMap and analyzed structural and textual properties as well as linguistic characteristics of the queries.

Introduction

Since the early 2000's, Internet usage for health information searching has increased significantly. According to the latest 2013 Pew Survey, one in three American adults have gone online to find out information about a medical condition. According to the Center for Disease Control and Prevention (CDC), in the United States, CVD is one of the most common chronic diseases and the leading cause of death (1 in every 4 deaths) for both men and women. Prior studies have shown that online resources are 'significant information supplement' for the patients with chronic conditions. One of the most common ways to seek online health information is via Web search engines, such as Google. Therefore, studying search queries can help us to understand Online Health Information Seekers' (OHIS) "information needs" and how they formulate search queries, which in turn, will empower us with knowledge to improve the health search experience, as well as to develop more advanced next-generation knowledge and content delivery systems. Although chronic diseases affect large population, very few studies have investigated online health information searching for chronic diseases and especially for CVD. We address this knowledge gap in the community by analyzing CVD related search queries. Some of the potential beneficiaries of this work are Web search engines and health websites.

Methods

In this study, we collected 10 million CVD-related search queries that direct users from Web search engines to the Mayo Clinic's consumer health information portal (MayoClinic.com). We performed the following analysis on the CVD related search queries: 1) Top search queries associated with CVD, 2) categorization of the queries into health categories using UMLS Metamap based on UMLS concepts and semantic types, 3) Structural analysis: length of the search queries, usage of search query operators and special characters in the search queries, and 4) types of search queries (keyword based, Wh and Yes/No questions), misspellings in the queries, and linguistic structure of the search queries.

Results and Discussion

Most of the top CVD queries are related to major CVD diseases and blood pressure (high/low). Top searched health categories for CVD are 'Diseases and Conditions' and 'Vital Signs'. Even though CVD prevention is possible, very few OHIS search for prevention while most of them search for symptoms and post diseases information (Living with, Diet, Treatment, Drugs). The average length of a CVD search query (3.88 words and 22.22 characters) is longer than that of a general search query, which implies that OHIS describe health information needs in more detail. Usage of a search query operator (4%) is limited and variation of 'AND' (AND, &, +) is used more often (95%) followed by 'OR'. Only 3.2% of the search queries contain at least one spelling mistake. OHIS predominantly formulate search queries using keywords followed by Wh-Questions and Yes/No Questions. Almost all CVD search queries have at least one noun.

Conclusion

We found that using Metamap and UMLS concepts/semantic type is a very good approach for categorization of health related search queries into health categories. This study extends our knowledge about online health information searching behavior, and provides useful insights for Web search engines, health-centric websites, healthcare providers, and healthcare-centric application developers.

Evaluation of the Health Level Seven Fast Health Interoperable Resources (FHIR) Standard as a Query Data Model for the Arden Syntax

Robert A. Jenders, MD, MS, FACP, FACMI
Charles Drew University & University of California, Los Angeles, CA

Abstract

Context: Arden Syntax is a standard that encodes knowledge as Medical Logic Modules (MLMs) but that lacks a standard query data model. Objective: Assess to what extent the Health Level Seven (HL7) Fast Health Interoperable Resources (FHIR) standard can represent MLM query data elements. Method: 340 MLMs containing 3268 queries were examined. Result: FHIR can be used to represent all these query data elements. Conclusion: FHIR adequately represents data queried using the Arden Syntax.

Introduction

Arden Syntax is an American National Standards Institute (ANSI) formalism supervised by Health Level Seven (HL7) for representation of procedural medical knowledge with the goal of facilitating sharing units of knowledge known as MLMs. Some site-specific changes must occur in order for a knowledge base to be transferred from one site to another. Key to minimizing site-specific changes is the standardization of database linkages, which in turn requires identification of a standard data model, vocabularies and query syntax. This is sometimes known as the "curly braces problem" of Arden because of the syntactic construct used to enclose these site-specific references[1]. The HL7 FHIR draft standard for trial use (DSTU) Release 1 is a new framework that allows references to data to be defined, represented in XML and bound to terminologies in modular components known as "resources." For example, concepts such as "patient," "medication" and "observation" are key FHIR resources, each with structured attributes that may be other resources. Increasingly, implementations involving HL7 standards and the standards themselves are being developed using FHIR. The present work was undertaken to assess FHIR's utility as a standard data model for queries in the Arden Syntax.

Methods

A previously assembled, robust convenience sample of MLMs was examined. The data query statements were extracted from these MLMs, and the data elements therein were identified. Each then was assessed to ascertain whether it could be specifically represented using FHIR DSTU Release 1.

Results

A total of 340 MLMs were pooled from 6 source CDS systems, including 19 from 3 vendor knowledge bases and 312 from 3 academic medical centers. MLMs concerned mainly with lab tests were the most common (138/331 = 42%), followed by clinical assessment or classification (75/331 = 23%) and medication (45/331 = 14%). The remainder addressed administrative and miscellaneous topics. Each MLM contained at least one READ statement with a data query. A total of 3268 queries were identified, and the data elements therein were compared to current FHIR resources to assess whether they could be represented. All the data elements in these queries could be represented by FHIR resources. Some data elements were complex and required linked resources to represent fully (e.g., bacteriologic reports) but were still representable in FHIR. Elements that were not directly representable in other data models previously proposed for the Arden Syntax such as the HL7 Virtual Medical Record (e.g., references ranges and pregnancy status) were representable in FHIR Of note, the primary time of query data elements in Arden is an implicit attribute of every query variable and is not explicitly represented, but this, too, is representable in FHIR.

Conclusions

FHIR is adequate to represent the data elements found in a large set of query statements in a corpus of Arden Syntax MLMs. Consideration should be given for use of FHIR to represent data elements in a standard way in queries in the Arden Syntax in order to facilitate knowledge sharing.

Exercise Intensity Adherence Improved by Remotely Controlled Cycle Ergometer

In cheol Jeong, PhD[1], Joseph Finkelstein, MD, PhD[1]
[1]Chronic Disease Informatics Program, Johns Hopkins University, Baltimore, MD

Introduction

Cycling exercise is an essential component of rehabilitation in older adults and individuals with various chronic conditions. Access to exercise facilities may in these individuals be limited by mobility impairment, lack of transportation or insurance coverage. Recently we introduced the interactive Biking Exercise (iBikE) system that was demonstrated to support patient-centered model of individualized self-care applications for telerehabilitation, disease management, and health promotion. However patients with compromised upper limb mobility may have difficulties in following their cycling exercise plan which affects safety and efficacy of home-based programs. To address this barrier, a remotely-controlled mode of cycling exercise intensity has been introduced. The purpose of this project was to compare adherence to cycling intensity during active (self-controlled) and passive (remotely-controlled) exercise.

System

The upper limb telerehabilitation system that supported the internet-controlled home cycling exercise consisted of a clinician unit, internet server and a home unit. The home unit consisted of a touch screen tablet, ergometer control unit, ergometer and wireless biosensors. LabVIEW 2011 SP1 was used to operate this system. A low-cost data acquisition device (NI USB-6008) which had plug-and play full-speed USB connectivity was designed to provide prescribed speeds by controlling the voltage output level in ergometer. The system design is shown in Figure 1.

Evaluation

The degree of adherence to prescribed exercise intensities was compared by investigating how well subjects followed varying target speeds at the self-effort mode that did not use the remote control mechanism, and the guidance mode that was controlled remotely. Two-minute periods of consecutive target cycling levels of 0.5, 1.0, 1.5, 1.25, 0.75 miles/hour were provided to subjects by displaying corresponding speed on exercise dashboard. The actual cycling speed was obtained by an electromagnetic sensor in the cycle machine with 50 Hz sampling rate. Each volunteer was assigned to both passive and active mode in a random order.

Results

Overall, 8 volunteers participated in the study. Absolute mean differences between prescribed and actual levels (AMD) and coefficients of variations (CV) were calculated to assess adherence. Average AMD for self-effort mode was: 0.054±0.006 (range 0.046-0.060 mi/hr), and for guidance mode: 0.022±0.010 (range 0.010-0.037 mi/hr); mean CV for the self-effort mode was: 9.622±6.300 (range 5.22-20.43%), and for guidance mode: 3.338±0.660 (range 2.79-4.46%). The differences between AMD and CV were statistically significant ($p<0.05$).

Discussion

The cross-over evaluation of exercise intensity adherence demonstrated higher adherence with upper limb exercise speed prescription during remotely-controlled mode compared to self-effort mode. We concluded that this approach may be a valuable option in frail individuals or patients with movement disabilities.

Social InfoButtons for Patient-oriented Healthcare Knowledge Support

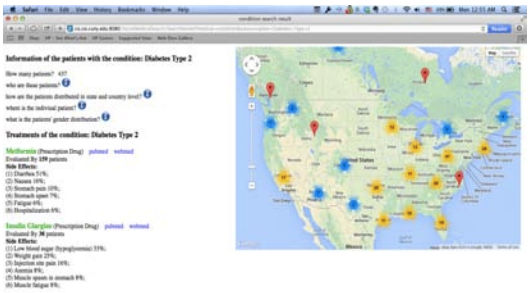
Xiang Ji, BE[1], Soon Ae Chun, PhD[2], James Geller, PhD[1]
[1] New Jersey Institute of Technology, Newark, NJ;
[2]City University of New York, College of Staten Island, Staten Island, NY

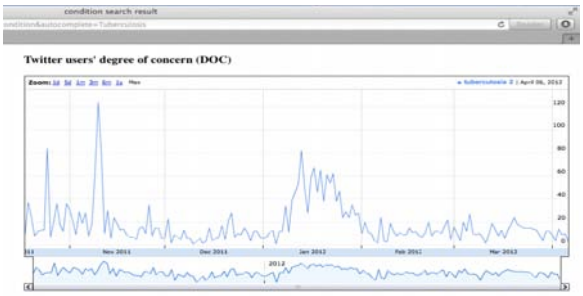
Abstract: Delivering contextually-relevant knowledge resources into EHR systems at the point of care was proposed as *Infobutton HL7 standard*. However, the *InfoButton* standard does not consider social media data or the patients' healthcare behaviors or practices. We present a *Social InfoButtons* system that collects patient-generated social media data and other open health data to provide insights on healthcare trends and patients' practices and issues, using the Semantic Integration model, that supports Social Healthcare Knowledge for clinicians, patients and policy makers.

Introduction: A study [1] showed that 34% of the Internet users utilized social media to read other patients' commentaries and experiences about health or medical issues. The InfoButtons system of Cimino et al. [3, 4] provides knowledge resources needed by clinicians but does not incorporate patient-generated social health data. With the Health 3.0 trend, it is increasingly becoming important to understand the patients' actual health practices, behaviors, trends and concerns. Our *Social InfoButtons* system generates contextually summarized information about social health practices by geographic or temporal dimensions, providing end-users (e.g. patients, clinicians, or government officials) with healthcare information, such as treatments, practices, conditions, experiences, sentiments, and behaviors reported by other patients through social media.

Methods: Providing integrated social health knowledge is challenging, since the online health data sources vary in formats and platforms. We present a semantic model for representing the integrated social health knowledge, and use Linked Open Data [2] to integrating heterogeneous social media health data sources. We developed the Social InfoButtons architecture to provide a social health analytics platform that can summarize, visualize and compare the contextually relevant health information for patients, clinicians, and healthcare government officials. The architecture consists of the data collector, RDF triple store, and analytics module. (1) The data collector extracts publicly available health data from various data sources, such as the social network site PatientsLikeMe, the government-maintained CDC website, the PubMed website, and the patient resource portal WebMD; (2) The extracted entities from different sources were integrated with RDF triples; (3) The coverage of the analytics module of Social InfoButtons ranges from simple SPARQL queries to interactive geographic and temporal visualizations to gather insights about social health trends and anomalies

Results: The integrated knowledge base currently has 612,017 triples representing 1228 conditions from different sources and their related information such as treatments, symptoms, and side effects of treatments. The figures below show the geographic knowledge retrieved by Social InfoButtons for Diabetes Type 2 (left), and a timeline trend of negative sentiments towards tuberculosis from Twitter users (right).





Conclusions: A Social InfoButtons prototype was developed to provide social health knowledge that is relevant to an end users' context. A semantic integration model and social analytics module are presented for social health knowledge, extracted from data sources ranging from social network sites, research communities, and government sites to patient Web resources.

Personalizing Statistical Models for Asthma Prognosis and Therapeutics

Hongyang Jia, Patricia Flatley Brennan, Shiyu Zhou, Junbo Son, Yu-Ting Hung
Department of Industrial and Systems Engineering, University of Wisconsin-Madison, Madison, WI

Abstract

Researchers often use statistical models when developing decision support methodologies for asthma prognosis and therapeutics. We conducted a selective literature review and contrast existing methodologies with our proposed statistical approach, which leverages new patient-generated data and addresses individual features.

Background

The Smart Asthma Management (SAM) project (NSF: IIS1343969) aims to apply a statistical modeling methodology employed in reliability engineering, to the challenge of asthma management. In literature, statistical models, e.g. Markov Models, Bayesian Networks, are most often used in asthma prognosis while Expert System forms the dominant methodology in recommending therapeutics. As patient-generated, frequently sampled data becomes ubiquitous, promising yet challenging opportunities arise to build alternative analytical method to capitalize it, and accelerate patient-centered asthma care.

Method

We reviewed selected literature within the scope of decision support methodology in asthma therapeutics and prognosis. We compared the model approaches on two aspects: purpose and data source, and then elaborated the comparison between SAM approach and traditional statistical methods.

Result

The results of selected literature review are presented in Table 1. All existing approaches leverage population-level data or expert experience to formulate models for either diagnosis or therapeutics. In SAM we propose to augment population-based prediction in three ways: First, SAM augments population prediction with continuous or frequently sampled data, for example real-time patient sensing or easy to capture self-reports rather than conventional clinical assessment data. Other statistical models are designed based on clinical data and cannot capitalize new data sources[1, 2]. Autocorrelation, missing data and imprecision are not addressed enough as well. We will construct a multistate model from population level estimates then refined with extension based on an individual patient's data. Thus, SAM will build a personalized diagnosis model for each patient while others use a generic model for every one[1, 2]. Third, because it incorporates both treatment and state indicators, SAM will provide recommendations for both diagnosis and therapeutics based on new data source. Overall, SAM provides new perspective on asthma diagnosis and therapeutics, and facilitates patient-centered asthma management.

Table 1. Contrast of different model approaches

Model	Purpose	Data Source for Model Building
Statistical Model	Diagnosis	Population
Neural Network	Diagnosis	Population
Expert System	Treatment Planning	Heuristics
Case Based Reasoning (AI)	Treatment Planning	Population

Discussion

Decision support technologies can capitalize on frequently sampled patient data, but the models to process that data will perform best if the model can manage the autocorrelation, missing and imprecision of patient-generated data.

Readmission Leakage Risk Stratification with Associative Classification

Yugang Jia, Lin Li, Usha Nandini Raghavan, and Nathan Cohen

Philips Research North America

Abstract

A high percentage of patient's readmissions[1] occur at other hospitals instead of the one they first admitted to, which is defined as readmission leakage. Associative classification method is applied to identify low and high readmission leakage patient cohorts for generating actionable insights for management purpose. Results show that admitted patient with non-acute cardiovascular disease or certain behavior pattern has a high chance of readmission leakage.

Introduction

Understanding and managing readmission leakage risk is very important for hospital to prevent revenue loss and improve their patient management cost-effectively in the whole continuum of care1. The identified leakage patterns can provide actionable insights to stratify the patients and support management improvement, including redesign of inpatient management practices and proactive outreach to patients, referring physicians and community hospitals to manage patient transitions and support care coordination.

Method and Results

Unplanned 30 days readmission data (around 77K) from eight large-scale hospitals in NY is extracted from Healthcare Cost and Utilization Project (HCUP) database (2009-2011) Agency for Healthcare Research and Quality, where the average readmission leakage rate is 28%. Associative classification method[2], is used to extract meaningful associations between patient features and their hospital choice. All patient cohorts with more than 5% of whole readmission population are identified. Then cohorts with more than 50% of readmission leakage or less than 20% of patient leakage are selected as high and low readmission leakage cohorts for rule generation respectively.

The 5-fold cross validation results as shown in left side of Figure 1 indicates the observed leakage ratio is statistically significant different cross three leakage risk levels (p-value < 0.01). If a hospital is capable of managing 10.8% readmissions (leakage risk classes), it can cover 19% leaked readmissions for leakage prevention.

Examples of identified high risk patient cohorts are shown in right side of Figure 1. Non-acute cardiovascular patients that discharged to home have significantly higher leakage risk compared the overall average (p-value < 0.01). For this type of patients, their leakage risk is tied to the patient satisfaction, which can be improved by inpatient management. Two other cohorts with significant leakage ratio are young male patients who live in metro area and patients with drug abuse (p-value < 0.01). To prevent their leakage, hospitals need to better maintain contact with patients by proactively outreach to patients, referring physicians and support coordination of care.

Lexical Term Standardization of ICD-11 Using Semantic Web Technologies

Guoqian Jiang[1], Harold R. Solbrig[1], Bedirhan T. Ustun[2], Christopher G. Chute[1]
[1] Department of Health Sciences Research, Division of Biomedical Statistics and Informatics, Mayo Clinic, Rochester, MN; [2] World Health Organization (WHO)

Abstract

As part of work plan of the World Health Organization (WHO), the lexical terms used in ICD-11 labels or properties of entities should follow a standard and homogeneous approach. The objective of the study is to develop and evaluate a solution to identify term heterogeneity in ICD titles using Semantic Web technologies.

1 Introduction

The beta phase of the 11th revision of International Classification of Diseases (ICD-11) started in May 2012. As part of work plan of the World Health Organization (WHO), the lexical terms used in ICD-11 labels or properties of entities should follow a standard and homogeneous approach. For example, the terms "cardiac," "renal" should always be used in ICD titles, definitions and values instead of the terms "heart," "kidney". The objective of the study is to develop and evaluate a hybrid solution to identify term heterogeneity in ICD titles.

2 Materials and Methods

We utilized a lexical toolset known as the Sub-Term Mapping Tools (STMT) developed at National Library of Medicine (NLM) [1]. Two main features of the tool were used: 1) to find all sub-terms for an entity; 2) to find all permutations of synonymous sub-term substitutions. We developed a Semantic Web-based wrapper service that links WHO ICD-11 content services with local STMT lexical sub-term services. Specifically, the wrapper service takes an ICD entity URI as the input (which retrieves the title of the ICD entity), and then renders the sub-terms of an entity and the synonyms of each sub-term in a Semantic Web Resource Description Framework (RDF) format [2] using the W3C standard Simple Knowledge Organization System (SKOS) signatures. Using the wrapper service, we harvested the sub-terms and their synonyms in RDF triples for all foundation entities (n= 29,445) and loaded them into an open source RDF triple store known as 4store. We enabled a SPARQL endpoint that provides standard SPARQL query services against the sub-term dataset and analyzed the dataset.

3 Results

We retrieved the sub-term pairs, in which the preferred label of a sub-term appears to be the synonym of the other sub-term, and identified 4,927 distinct sub-term pairs. We manually reviewed a small subset of the sub-term pairs and concluded that they reflect reasonably well the term heterogeneity in ICD titles. For example, for the sub-term "bleeding," we identified its synonymous sub-terms "haemorrhages," "haemorrhage," "haemorrhagic," "hemorrhage," "hemorrhagic," "blood loss," "ruptured," "rupture," "spot," and "spotted". The frequency distribution of such sub-terms would help the decision-making of subject-matter experts in choosing a preferred sub-term out of its synonymous sub-terms so that the preferred sub-term could be used in ICD titles in a consistent way. We plan to work with WHO to conduct a comprehensive review for the set of sub-term pairs and their frequency distribution in ICD titles.

4 Conclusion

In summary, we developed a hybrid approach that combines an NLP-based lexical tool with a Semantic Web-based approach, which would provide an effective and scalable solution for lexical term standardization of ICD-11.

Impact of barcode design on the medication administration process

Junghee Jo, MS[1], Jenna L. Marquard, PhD[2], Lori A. Clarke, PhD[2], Philip L. Henneman, MD[3,4]

[1]Electronics and Telecommunications Research Institute, Daejeon, Korea; [2]University of Massachusetts, Amherst, MA; [3]Baystate Medical Center, Springfield, MA; [4]Tufts University School of Medicine, Boston, MA

Abstract

Barcode medication administration (BCMA) systems have been recommended to help reduce errors during the verification of patient identifiers (VPI) process. BCMA manufacturers claim their systems ensure the "Five Rights" of medication administration. Such claims are valid, however, only if healthcare workers follow a medication administration process consistent with the specific barcode design being used. This poster shows how the VPI process depends on the barcode design, which often varies by state, healthcare organization, and manufacturer.

Introduction

Failure to perform the VPI process correctly is one of the major causes of medication errors.[1] BCMA has been shown to be effective in reducing VPI errors[2], but healthcare workers need to be aware of what information is encoded on the barcodes and perform a VPI process that is appropriate for that design.

Observations

We considered several barcode designs (2 designs are shown in Figure 1), where the ID band and medication label barcodes are encoded with zero, one, or two patient identifiers, and show how the VPI process during medication administration depends on this design.

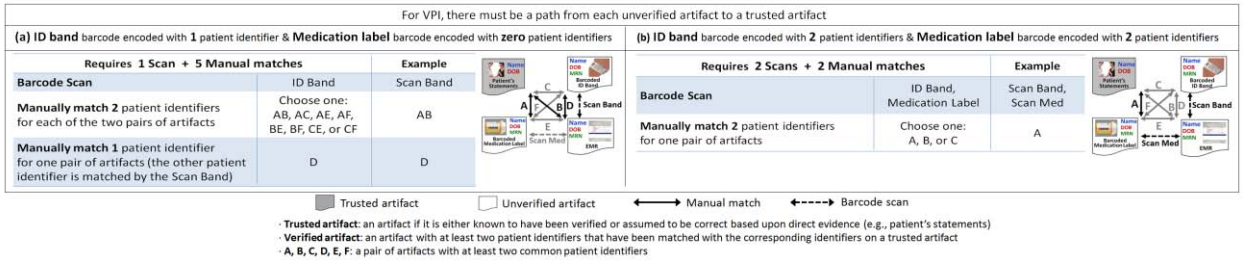

Figure 1. The VPI process varies by choice of barcode design; 2 designs are shown.

For each design, we determined the percentage of nurses complying with the Joint Commission guidelines for VPI by analyzing data collected from a previous clinical simulation study in which nurses administered medications to a mock patient[3]. Regardless of which design the nurses believed to be applicable, few nurses complied with the guidelines; the results ranged from 12% for Figure 1(a) to 32% for Figure 1(b).

Recommendations

Our findings suggest several ways to improve compliance, which may help reduce errors. First, healthcare workers should be aware of the information encoded on barcodes, as the appropriate VPI process depends on the barcode design. Second, as will be illustrated in the poster, encoding two patient identifiers on the ID band and medication label barcodes simplifies the process and reduces the number of required manual (i.e., visual and verbal) matches. Third, teaching health care workers a specific sequence of actions for VPI based on the chosen barcode design will prevent healthcare workers from having to choose among different alternatives. Finally, since unusual situations are bound to arise, healthcare workers should learn the underlying principles for correctly performing VPI.

Online Quiz Taking: Does Allowing Repeated Tries Without Penalty for Incorrect Responses Increase Guessing?

Craig W. Johnson, PhD, Craig Harrington, MS, MSSW,
Rodney Howell, BSCET, Taiwo Akinwande, RN, BSN
University of Texas-Houston Health Science Center

Abstract

The study examined online quiz-taking behaviors of 121 students in a statistical methods in health informatics course. Four milestone lesson quizzes allowed repeated attempts per each multiple-choice question, with grades determined by performance on the final attempt. Results revealed incorrect responses increased and accuracy of responses decreased on later quizzes, consistent with a hypothesis that: Students learn to guess more frequently. Additional research needs to assess whether effects are related to lesson difficulty levels.

Background

According to cognitive learning theories, mental activities like practicing and rehearsing, are vital to the acquisition of knowledge[1(p6-7)]. Online techniques may provide fewer controls over the learning environment, allowing students to interact in unexpected ways. This study analyzes three operationalizations of measures of guessing where online students may retry each quiz question without penalties.

Research Question

Do changes that are consistent with increased frequency of guessing – specifically number of tries per quiz (nbr_tries), first-try correct responses (score), and percent of total tries that are correct on the first try (pct_correct) – occur across four quizzes selected within a course or across course iterations?

Method

Data were deidentified lesson responses of 121 students from 2008 to 2013. Four representative online hypertutorial lessons were selected from the 22 covered during a statistical methods in health informatics course. Selected lessons were separated by two-week intervals. A multivariate split-plot design included year as a between-subjects factor and lesson as a within-subjects factor and three dependent variables: nbr_tries, score, and pct_correct.

As variables were extremely positively skewed in the presence of unequal sample sizes and violated sphericity and Box M Test assumptions, the research employed SPSS v.22 to conduct parametric and nonparametric doubly multivariate analyses using the GLM/MANOVA Repeated Measures procedure for tests of linear, quadratic, and cubic trends among within-subjects effects. Puri-Sen *L* statistics from the nonparametric trend test analyses were calculated using ranked data.[2] Decisions regarding statistical significance of nonparametric tests did not differ substantively from those of parametric tests; ergo results of the more familiar parametric tests are reported.

Results

Over the four lessons, significant ($p < .005$) linear and cubic trends and profile plots revealed small mean differences in earlier lessons followed by significant and substantial mean differences that leveled off for later lessons. Score and pct_correct significantly decreased and nbr_tries increased with later lessons.

Discussion

Results are consistent with the hypothesis that guessing increases across lessons as shown by an increase in the number of tries per quiz, decreases in the number of correct responses on the first try of a quiz, and the percent of total tries that are correct on the first try. Analyses did not control for lesson difficulty levels and students may have been willing to select less certain answers as they experienced no penalty for incorrect responses. While the increased numbers of tries per quiz, decreased numbers of correct responses on the first try and percent of total tries correct on the first try were consistent with the guessing hypothesis, future research should address such potential threats to validity.

An Institutional Strategy to Support Clinical Research with Centrally Managed Custom Data Repositories

Stephen B. Johnson, PhD[1], Thomas R. Campion, Jr., PhD[1], Nonie E. Pegoraro, MA[1], Leon Rozenblit, JD, PhD[2], Charles Tirrell[2], Curtis L. Cole, MD[1]

[1]Weill Cornell Medical College, NY, NY; [2]Prometheus Research LLC, New Haven, CT

Introduction: Healthcare organizations face significant technical and organizational challenges to support clinical research. These barriers have historically led to fragmentation of the research enterprise, which in the extreme force individual researchers to manage their data separately. In some cases, groups of researchers who share common interests have developed custom data repositories that meet their collective needs.[1] These approaches do not scale as an institutional strategy. When there are multiple local repositories, many data management activities are redundant, regulatory processes are convoluted, and opportunities for data sharing and collaboration in new areas are limited. One potential institutional strategy is to develop a centralized data repository, typically by making operational clinical data available to researchers for secondary use.[2] This approach often fails to meet the specialized needs of heterogeneous research groups for primary data collection, study management, local data integration and curation. Exclusive focus on central processing can reduce opportunities to improve research productivity.[1] We describe here a new strategy that focuses on the needs of local research groups, while attempting to achieve economies of scale at the institutional level with a sustainable funding model.

Methods: Architecture for Research Computing in Health (ARCH) partitions information technology for clinical research into external data sources, shared infrastructure and custom research data repositories. External sources include electronic health records, research administration systems, electronic data capture and biobanks. Shared infrastructure includes a *loading zone* where external data can be organized and integrated, and a *working zone* where data are transformed into structures needed locally.[2] Research data repositories provide highly customized, self-service facilities for extracting data for analysis and identifying cohorts as well as data quality assessment and exploration. Shared components are largely funded centrally while custom components are charged back. Both shared and custom components are implemented using an open source platform (RexDB), which offers a model-driven architecture, meta-data management, configuration services and web-based query language (RexQL).

Results: The institution adopted the ARCH strategy with significant financial support from the Joint Clinical Trials Office and the Clinical and Translational Science Center to support hardware and staff for shared infrastructure, as well as a scientific advisory board to vet requests for creating new custom repositories. In addition, two research groups (anesthesia and digestive care) have adopted the strategy by investing in services to provide custom data transformations, user interfaces and reports. The demand for additional repositories from other research groups is high, with three planned for the coming year (pediatrics, urology and hematologic oncology) and new requests added every month.

Discussion: The ARCH strategy enables an institution to centralize research infrastructure for secondary data use, regulatory compliance, data transformation, quality assessment, security, needs assessment and training. Local research groups are fully empowered to collect and integrate specialized data, with customized workflow to maximize scientific coloration and research productivity. A transparent model for cost sharing ensures financial sustainabililty.

Semi-Automated Method to Extract Semantic Information from EHR Flowsheet Data for Pressure Ulcer Research

Steven G. Johnson, MS[1]; Jung In Park, BS, RN[2]; Matthew D. Byrne, PhD, RN[3]; Beverly Christie, DNP, RN[4]; Lisiane Pruinelli, MS, RN[2]; Suzan Sherman, PhD, RN[4]; Bonnie L. Westra, PhD, RN, FAAN, FACMI[2]

[1]University of Minnesota, Institute for Health Informatics; [2]University of Minnesota, School of Nursing; [3]St. Catherine's University; [4]Fairview Health System

Problem

Significant amounts of useful data are contained in non-standard, semi-structured electronic health record (EHR) flowsheet data. The goal of this study was to develop a method for semi-automatically mapping this data into semantic concepts in order to define a data model for pressure ulcer research.

Introduction and Background

Pressure ulcers occur for more than 2.5 million people each year and are estimated to result in $9.1B to $11.6B in unnecessary health care costs and causes pain, infection risk, increased hospital stays, and death [1]. Evidence-based practice guidelines exist for prevention of pressure ulcers and documentation captured in electronic health records (EHRs) can be used to relate patients' conditions and care provided to evaluate the effectiveness of these guidelines on outcomes. However, EHR documentation must be mapped to standard clinical models and concepts in order to analyze the benefit of these practices. A standard model for pressure ulcer data is being developed from HL7, but EHRs capture most pressure ulcer related data as customized fields.

Methods and Data Source

Clinical data, including flowsheets, were extracted from one Midwest health system's EHR and loaded into a clinical data repository at the University of Minnesota. A subset of 200,000 records was extracted and analyzed to develop a clinical data model and map concepts to national data standards to link patient characteristics and care to pressure ulcer outcomes. The flowsheets contained 15,000 different types of data, which would have been difficult and error prone to normalize and standardize for research. Therefore, a semi-automated method was developed to map these types of data into standard SNOMED CT concepts. The method uses natural language processing (NLP) tools on the flowsheet field definitions and attribute information to match semantically equivalent concepts.

Results / Discussion

The semi-automated process produced a set of SNOMED CT concepts that were used to create a model of pressure ulcer data useful for research. The method uncovered a number of data fields that were really the same concept and also helped group the concepts that were more closely related, which simplified the resulting model. This same process can be used with any health system's data to efficiently map custom flowsheet data fields to standard concepts and extract the relevant pressure ulcer related information.

The Extent to which U.S. Hospitals Promote Their Patient Engagement Activities and Outcomes: Preliminary Results of Quantitative Content Analysis Research

Josette F. Jones, Maryam Zolnoori, Samar Binkheder, Katherine Schilling, Michelle linox, Lakshmi Ravali Pondugala
School of Informatics and Computing, Indiana University- Indianapolis, IN 46204

Introduction

Patient engagement is "a concept that combines patient activation with interventions designed to increase activation and promote positive patient behavior, such as obtaining preventive care or exercising regularly [1]." Within the scope of healthcare information technology (HIT), patient engagement is managed by technologies that can be used for myriad purposes ranging from enabling patients to view their medical histories online, to communicating with practitioners online, to using electronic platforms for capturing and disseminating large quantities of patient data. The goals of technology trends around patient engagement include improving accuracy of diagnosis and treatment of patients.

Purpose

The purpose of this study is to describe and make inferences regarding the extent to which hospitals in the U.S. meet patient engagement criteria delineated by the National eHealth Collaborative (NeHC) [3].

Methodology

A quantitative content analysis method has been used to examine and code content from the website of 100 hospitals nationwide. The hospitals were randomly selected from a comprehensive list on health.usnews.com, Hospitals were categorized as "small," "medium," or "large" based on the number of outpatient visits recorded annually. The contents of 100 hospital websites are being analyzed using a patient engagement framework which describes an inclusive platform for achieving patient engagement [3]. This framework includes five stages for patient engagement: 1) inform me, 2) engage me, 3) empower me, 4) partner with me, and 5) build my e-community. In order to quantify the results of hospitals website analysis, data are labeled with the following binary criteria: applicable criteria found (+1), criteria not found (-1), not sure (0), and not applicable (9). Statistical techniques including t-test and chi-squared test are used to analyze relationship between patient engagement criteria and sizes of hospitals, hospital rankings, and number of outpatient visit. In addition, a descriptive analysis will be provided for every section of the framework to better understand how hospitals promote patient engagement through their public websites.

Preliminary Results

The researchers expect that the results of data analysis will illustrate the extent to which small, medium, or large hospitals (based on counts of outpatient visits) inform, engage, empower, and collaborate with patients. Results will reveal the strengths and weaknesses of hospital websites in demonstrating an organization's relative levels of patient engagement, as well as the extent to which the achievement of Stage 2 requirements of the Meaningful Use legislation have been achieved and communicated.

Conclusion

As we move from a physician-centric model of healthcare to a patient-centric model, the role of hospitals in publically promoting their patient engagement activities and outcomes becomes increasingly important. The findings of this study will provide a snapshot of current affairs and a discussion of relevant trends and themes.

Automated Early Warning System for Monitoring Workflow, Evaluating Patient Care and Predicting Risk in Secondary Care in the UK.

Julie S Jones-Diette, PhD[1],
Michael Brown[2], Gemma Housley[1], Jim Hatton[3], Dominick Shaw[1, 4]

[1]East Midlands Academic Health Science Network, Nottingham University Hospitals NHS Trust, Nottingham, UK. [2]Horizon Digital Economy Research Institute, University of Nottingham, UK. [3]Deputy-Director of Information and Performance, Nottingham University Hospitals NHS Trust, Nottingham, UK. [4]Division of Respiratory Medicine, School of Medicine, University of Nottingham, UK.

Introduction

The presentation will discuss the UK's first single-source big-data technology platform for NHS secondary care. Key to its technical and commercial innovative potential is the use of key data sources which are already collected daily by all NHS Trusts in the UK. To date there is no known integration of these sources and their combination will permit accurate assessment, information dissemination, near real-time monitoring, and clinical adverse incident measures at unprecedented levels in the NHS. The UK National Health Service (NHS) deals with 1 million patients every 36 hours. Hospital Trusts in the UK utilise many automated and bespoke systems to coordinate this level of care across all departments producing unique opportunities for data linkage, the prediction of risk and a system which can pull all disparate data streams together for resource planning and operational efficiency which is essential for the future of patient care.

Aim

The Nottingham University Hospitals has been chosen as the pilot site to launch a tool which will build on both existing infrastructure at the Nottingham University Hospitals and already established methods for the management of operational efficiency within the aviation sector. The resulting software system will improve patient experience, support resource planning and optimise hospital efficiency.

Method

Our award winning workflow handheld monitoring system[1], using the wireless system Nervecentre[2], will be combined with other data sources including the NUH Data Warehouse, DATIX Safety Database, ORMIS Electronic record of Theatre events, ED patient flow data, EMAS Ambulance statistics, ESR Electronic Staff Record and E-rostering across the two large teaching hospitals within the University of Nottingham NHS Trust (QMC and City Hospital Campus). A suite of applications for airport optimisation of passenger flow and operational efficiency will be adapted for use in the NUH secondary care setting using information assimilated from these data streams.

Results

The initial output will be a rich database of hospital and patient activity across the two hospitals including current resource allocation within the hospital. Using this information, data analysis will determine the most informative parameters for the prediction of future resource requirement and patient kinetics including areas for potential overburden. Once linked with suitable visualisations designed through a human-factors process with one of our partners, The Horizon Digital Economy Research Institute, we will use multi-method research techniques (walkthroughs, technology-enhanced diary studies, interviews, and surveys) to evaluate the degree to which the data infrastructure improves the sharing and usage of the data within operational and strategic affairs.

Conclusion

The final product will be a real-time suite of applications for patient care and hospital efficiency and for estimates of risk at the ward or hospital level. We will design the suite to support data collected by other NHS Trusts to adapt the system for a UK roll out to ultimately provide shared clinical benefits and evidence-based improvements to workflow nationally.

Tissue-Experiment Inventory: A System to Enable Cataloguing of Experimental Results in Association with Tissue and Participant Information

Norman P. B. Joseph[1], Leonid Kvecher[1], Brenda Deyarmin[1], Lori Sturtz[1], Frank J. Cammarata[1], Caroline Larson[1], Craig D. Shriver[2], Richard J. Mural[1], Hai Hu[1]
[1]Windber Research Institute, Windber, PA; [2]Walter Reed National Military Medical Center, Bethesda, MD

Abstract
Historically our experimental results were managed neither systematically nor centrally. Experiments were performed on a variety of platforms and for diverse projects, and results were not directly linked to other tissue information. To solve this problem, we designed, developed and implemented a process to systematically collect and catalog experimental results in association with the tissue information, permitting us to link these results to existing clinicopathologic data in a data warehouse.

Introduction
Windber Research Institute (WRI) developed the Data Warehouse for Translational Research (DW4TR) with an advanced analytical workflow platform in collaboration with InforSense/IDBS[1]. WRI also maintains a large tissue bank of biological samples for cancer research. DW4TR contains participants' demographics, medical history, life style, risk factors, pathologic annotations of the biospecimens as well as biomarker information assayed by immunohistochemistry and FISH. However, the experimental results derived from these samples were historically managed and stored separately by individual Primary Investigators (PIs). WRI undertook the current work realizing it would be beneficial for researchers to be able to link experimental results directly to elements of DW4TR.

Methods and Results
We reviewed internal records to identify projects, PIs, technicians and platforms under which experimental results from tissue bank data had been generated. PIs were asked to provide lists of requested samples; technicians were asked to provide the locations for experimental results identified by samples and participants. All information was confirmed against the data in the DW4TR. Electronic versions of all result files were then copied to a central archive location, and tables were created in the DW4TR to track project, sample and experimental results location information. The analytical workflow builder (see Figure 1A) was used to develop workflows for integrating experimental results information with these tables, and for linking this information to sample and participant data already existing in the DW4TR. In addition, a workflow was developed to perform ad-hoc queries on the resulting tables, and published to the portal (Figure 1B). We are in the process of expanding this application to enable lab scientists to directly deposit their experimental results into this tissue-experiment inventory.

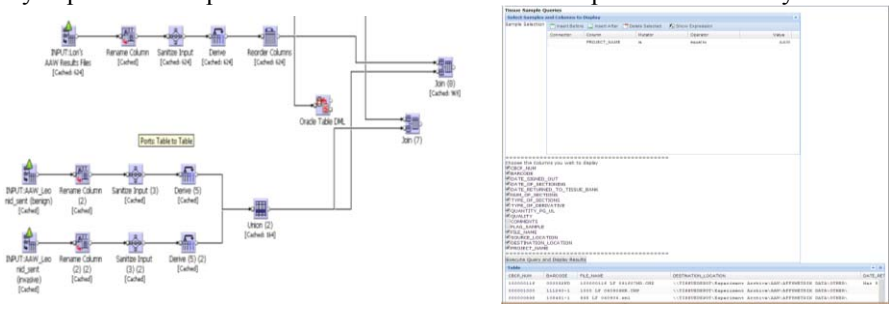

Figure 1. (A) Part of the analytical workflow for data integration. **(B)** Sample portal ad-hoc query.

Conclusions
The Tissue-Experiment Inventory allows us to link clinicopathologic and sample information directly to experimental results, facilitating research and enabling new discoveries.

A Statistical Study of Words Used in Chinese Clinical Documents

Meizhi Ju,BS,Haomin Li,PhD*,Huilong Duan PhD
Zhejiang University, Hangzhou, China

Abstract

Corpus is important for developing NLP (Natural Language Processing) technology. For many reasons, corpus of clinical document is very valuable for MLP (medical language processing), especially in China. In this study, we first established a corpus of Chinese clinical documents, then calculated word normalized frequencies based on counting words in different categories, and finally represented them by data visualization.

Introduction

80% of the clinical documentation that exists in healthcare today is unstructured. Therefore, MLP has been widely studied in health care IT industry. While, MLP research in Chinese language is scarce. Lack of corpus of Chinese clinical documents is one of the obstacles. In this primary study, we collected clinical documents and did a basic statistical study of that corpus. Moreover, presenting word and frequency in a visual and intuitive form can be a basis for visualizing analysis research at a deeper level. Such researches based on medical lexicon corpus will be of great value. The corpus built in this research and the related statistical study will better serve further MLP research.

Method

Total 63,172 Chinese clinical documents were collected from a Chinese hospital to establish this corpus. Each document was firstly segmented in sentences and clauses based on punctuations. Then each clause was segmented in words or phrases based on a Chinese word segmentation library named Pangu. After that, we annotated each word with its part-of-speech and another eight customized attributes which could afford an opportunity to classify words.

To give a basic idea about the words used in Chinese clinical documents, we counted the frequency of each word in the corpus. In this step, Arabic numbers, punctuations, names and English letters were excluded from the study.

The clinical documents from different departments or of different note types have unique word usage. To compare this, the normalized word frequency was calculated. For each category, we counted the total number of words as TN and then counted the number of each word as N. We calculated the word normalized frequency through N divides TN for each word. Meanwhile，we sorted these words in a frequency descending order.

To provide a whole picture of the word used in Chinese clinical documents, we have designed a visualization tool to generate charts on word, word normalized frequency and category. In the chart, the horizontal axis represents each specific category. In the vertical direction of each integer point, we place bubbles in descending order related to word normalized frequency and the number of bubbles depends on how many we have selected. The size and color of each bubble is used to represent word normalized frequency and Chinese word, respectively. With purpose of getting distribution rules of words, we count sub-language classes attached to words as one customized attribute in different note types or departments and do large amount of analysis combining with a number of bubble charts.

Result

Through segmenting 63,172 Chinese clinical documents which involves 31 departments and processing the resulting words, we have established a Chinese corpus which involves 324,000 sentences, 12 million clauses, and 50 million words. Symptoms, diagnosis and body parts relevant as well as medication words count for a large percentage while chemical, time and organism words count for a very small percentage in different departments and note types excluding all irrelevant words. In different note types, contrary to operative notes and discharge summaries, pathology notes and progress notes have a large percentage on all sub-language classes especially on diagnosis and symptom sub-language classes. In different departments, emergency department has the lowest rate in diagnosis and symptom sub-language classes, and generic medical department has the highest rate. In addition, the trends of ups and downs about sub-language classes in different departments as well as note types don't have apparent differences.

NLP enhances Quality Care Measures in Heart Failure

Ravikumar K.E., Wagholikar K.B., and Liu, H
Department of Health Sciences Research, Mayo Clinic, Rochester, MN, 55901

Introduction: Congestive Heart Failure (CHF) is one of the leading causes for death across the globe. Ensuring quality care to CHF patients has been a great challenge in clinical practice. HEDIS[1] and NHQM[2] have prescribed guidelines to ensure quality care in the management of CHF patients. Identifying the patient with CHF very early is the first step in ensuring quality care. Clinical notes have been the major source in accurately identifying whether the patient has CHF.

Objective: The chief objective of the study is to investigate the role of NLP in the identification of CHF patients to ensure quality care.

Methods: Our approach to detect evidence for CHF in clinical notes of patient consists of the following 4 steps: 1) *Compile a comprehensive dictionary to identify terms relevant to CHF in the clinical notes* - Based on the criteria used by the nurse abstractors we compiled a dictionary from UMLS[3], which consists of 330 terms and organized into main categories a) Disease/Phenotype terms that describe CHF 2) Drugs used to treat CHF (Digoxin, Coreg), 3) Co-morbid disorders such as renal failure, Hypertension etc. 4) Drugs to manage secondary factors (Lasix etc.). The final dictionary consists of 330 terms. 2) *Use natural language processing (NLP) term-spotting techniques to detect those terms in clinical notes* - We used MedTagger[4], a Aho-Corasik lookup approach to detect the various terms compiled in the dictionary. 3) *Classify patients whether they have CHF or not based on the terms identified in the text* – We had two rules to classify if the patient has CHF. If the clinical note of a patient contains terms that describe both CHF condition and drug used to treat CHF then the patients are classified as CHF patients. If the term from only one of the category is mentioned then the secondary information such as presence of drugs to treat renal failure is relied upon to confirm the CHF condition of a patient.

Data set – Table 1 summarizes the statistics of the data sets that we used in this study. Our study was on 490 patients who visited Mayo Clinic over a period of 2 months (60 days starting May 15th 2012) with complaints related to heart disorders. The records were manually analyzed by four nurse abstractors and classified as CHF patient based on the evidences provided by the physician, lab tests, drugs prescribed, etc.

Table 1 – Data statistics

Data Set	Total Patients	Total clinical notes
Training	376	6239
Test	114	2078
Total	490	8317

Experiments: We retrieved 8317 clinical notes related to 490 patients. We used 6239 notes (from 376 patients) for training and the remaining (2078 from 114 patients) for testing. The training data was used to refine the dictionary and fine-tune the rules to improve the performance of the system on the training data.

Results and discussion: The system achieved a precision, recall and F-measure of 72.38%, 96.23% and 82.61% respectively on the blind test data. The first rule that considers the combined presence of terms from the first two categories is a strong indicator for CHF resulting in very high precision but lower recall (Row1 of Table 2). However it the second rule that classifies a patient to have CHF based on the presence of terms either the first or the second category significantly boosted the recall (96%). However, we observed significant drop in the precision (from 93% to 72.38%) due to the second rule (Row2 of Table 2). This rule helped the system to achieve the best overall F-measure.

Table 2 – Evaluation on test data

System	Precision	Recall	F-Measure
Rule1	91.17%	63.42%	74.80%
Rule 2	72.38%	96.23%	82.61%

Conclusions: We conclude that NLP based techniques significantly helped in the process of early identification of CHF patients. This is very important to ensure quality care and early intervention to the patients while treating for heart failure.

Methods for Early Stakeholder Engagement for Implementation of Health Information Technology

Megha Kalsy, MS[1], Natalie Kelly, MBA[3], Jennifer H. Garvin, PhD MBA RHIA[1, 2, 3], Mary K. Goldstein MD MS[4,5]
[1]Department of Biomedical Informatics, [2]Division of Epidemiology, University of Utah, Salt Lake City, UT;
[3]IDEAS Center, Salt Lake City Health Care System, Salt Lake City, UT; [4]VA Palo Alto Health Care System, Palo Alto, CA, [5]Center for Primary Care & Outcomes Research, Stanford University, Stanford, CA

Abstract

As part of a Department of Veteran Affairs (VA) study, we undertook early stakeholder engagement in order to increase adoption and uptake of an automated system. We used semi-structured interviews and thematic analysis to understand the context of implementation using a combination of the Promoting Action on Research Implementation in Health Sciences (PARIHS) framework of Implementation Science and the Socio-Technical Model of Health Information Technology to inform our work. We identified themes associated with four dimensions of the socio-technical model: hardware and software, clinical content, workflow and communication, as well as internal organizational features that related to barriers and facilitators of our anticipated implementation.

Introduction

Our early stakeholder engagement process sought to understand the context of an anticipated implementation of an automated quality measurement system for inpatients with congestive heart failure. We used the Promoting Action on Research Implementation in Health Sciences (PARIHS) framework[1], which includes the elements of evidence, context, and facilitation, as well as the Socio-Technical Model of Health Information Technology (HIT), which includes the following 8 dimensions; 1) hardware and software, 2) clinical content, 3) human-computer interface, 4) people, 5) workflow and communication, 6) internal organizational features, 7) external rules and 8) measuring and monitoring, of which we used 4, to guide our approach. Evidence provides the clinical basis for the system, and we examine the context or environment in which the implementation will occur. Prior studies have shown that HIT can be used as a facilitator of evidence-based practice[2] and by using Implementation Science we hope to increase adoption and uptake of our system.

Methods

We used a snowball sampling technique to identify interviewees beginning with VA key informants. Key informants provided a broad understanding of QM related to inpatient chronic heart failure within the VA. We also interviewed other subject matter experts based on the recommendations of the key informants, and/or their job category. We developed an interview guide and used it to undertake interviews. Two independent note takers populated the interview guide, summarized the interview and then combined them into a single summary through a consensus process. The summarized interview was then sent to each interviewee for review and editing (validation). We used the collective set of validated summaries to generate preliminary themes (codes) to answer our research questions.

Preliminary Results

We interviewed 14 stakeholders; key informants consisting of VA Quality Management (QM) and measure automation experts with a minimum experience of 5 years working in the VA and a minimum experience of 5 years working in QM and subject matter experts consisting of VA employees with job categories such as: clinical quality specialists; quality management professionals, clinicians and pharmacists; and clinical program analysts. Key informants and subject matter experts' experience in the VA ranged from 2-35 years, and from 2-33 years in QM. Themes associated with internal organizational features related to: use of evidence based care, a culture of continuous quality improvement, and routine use of quality control reporting as a feedback loop. The main theme related to hardware and software was that the VA has multiple informatics tools for clinical care and extensive supporting informatics infrastructure. Themes associated with clinical content related to the importance of medication reconciliation, the presence of clinical data accessible for determining guideline-concordant care. The workflow and communication themes related to workflow associated with patient monitoring, the need for quality measurement data for timely decision making, and the impact of transitioning from retrospective measurement to the potential use of automatically extracted data that could be used in clinical decision support systems (CDSS).

Conclusion

The early stakeholder engagement process is essential for providing information that is useful in system design for successful implementation of an automated system.

Benefits and Challenges of a Height Sensing Approach for In-Home Gait Speed Detection

Avinash Kalyanaraman[1], Blaine Reeder, PhD[2], Kamin Whitehouse, PhD, MS[1]
[1]University of Virginia, Charlottesville, VA, [2]University of Colorado, Aurora, CO

Abstract

Changes in gait speed are a predictor of functional change in older adults. As the developed countries of the world experience demographic shift due to population aging, there is a need for informatics-based solutions to support independent living for older adults. This poster discusses potential benefits and challenges of applying a field-tested height sensor to the problem of in-home gait speed detection as an early indicator of functional decline.

Introduction

Early detection of functional decline is important to provide timely interventions that prevent adverse events and threaten the independence of older adults in the community. Detection of changes in gait speed is one strategy to monitor functional change in older adults at home[1]. *Doorjamb* is a door-mounted multi-sensor that integrates motion and height sensors and has been used to reliably track room occupancy for multiple people in home energy efficiency studies[2]. The purpose of this poster is to identify issues in the application of the Doorjamb sensor to the problem of in-home gait speed detection and present initial walk test results for a member of our research team. Walk test data from additional trials will be included for presentation at the AMIA symposium in November 2014.

Benefits and Challenges

One potential benefit of using Doorjamb to measure in-home gait speed is that it is a field-tested technology that will go to production in the near future. Another benefit of Doorjamb is that it was developed to disambiguate multiple residents to track room occupancy. However, one challenge is determining the reliability of Doorjamb to disambiguate multiple residents when measuring gait speed. Another challenge is to understand the potentially high variability of in-situ gait speeds to provide a meaningful measure of gait speeds for different individuals at home.

Walk Test

As a proof-of-concept, a member of the research team performed eight individual walk trials on an "ideal" 10'+ straight-line course, moving toward and perpendicular to the Doorjamb sensor (Figure 1). The blue bar indicates ground truth walking speed as measured by a DSLR video camera. The red and green bars are different ways of estimating walking speed using the doorway sensor. The third and fourth trials captured poor readings of the person walking, making these sensor measurements unreliable. Of the remaining trials, error rates were approximately 0.05m/s or less.

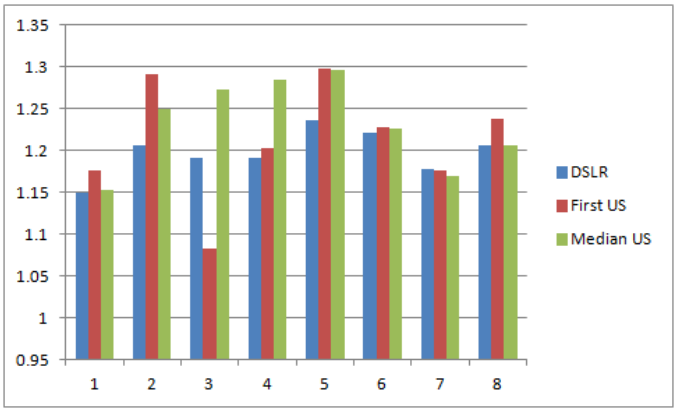

Figure 1. Initial proof-of-concept walk test results

Discussion

Based on our prior experiences in developing custom integrated sensors, we believe we can improve accuracy through additional sensors and algorithm refinement as well as capability to accommodate other than ideal straight-line walks. Future research will include formal walk trials that enroll a mix of young and older adults in a laboratory setting to validate Doorjamb performance before moving to field studies.

ABSTRACT

Youjeong Kang MPH, RN[1]
[1]University of Pennsylvania, School of Nursing, Philadelphia, PA

Patient characteristics associated with reshopitalization in older adults with heart failure receiving telehomecare.

Problem: Heart failure (HF) is the leading cause of rehospitalization in the United States. One potential way to reduce HF rehospitalizations is through the use of telehomecare technology. However, studies on telehomecare use in the United States have demonstrated inconsistent results in reducing HF rehospitalizations and lengthening time to rehospitalization. Additionally, little is known about risk factors for rehospitalization during the course of a telehomecare episode.

Study purpose: the aim of this study is to identify patient characteristics associated with HF rehospitalization, and with time-to–first rehospitalization, during receipt of telehomecare services.

Methods: This is a non-experimental retrospective analysis of the Outcome Assessment Information Set (OASIS) dataset from Medicare beneficiaries with heart failure, who were provided telehomecare services by a private home healthcare company. This study used the most current version of the OASIS dataset (OASIS-C) to examine patient characteristics associated with rehospitalization by using multiple logistic regression and survival analysis techniques.

Results: In terms patients with a documented formal pain assessment, patients who indicated severe pain using a standardized assessment tool, were 1.85 times more likely to be rehospitalized than patients without severe pain (p=0.01) within 60 days. Patients who had skin lesions or open wounds were twice more likely to be rehospitalized than those without skin lesions or open wounds (p=0.02) within 60 days. Patients who were able to safely dress their lower body had were nearly three times more likely to be rehospitalized than patients who were able to dress without assistance if clothing and shoes are laid out or handed to them (p=0.01) within 60 days. Patients with urinary incontinence were at 1.35 times greater risk of rehospitalization than those without urinary incontinence (p=0.03) at any given point in time. Patients who had hospitalizations more than twice in the past 12 months were at 1.40 times greater risk of rehospitalization than those with fewer than two hospitalizations in the past 12 months (p=0.03) at any given point in time .

Conclusion: This study's findings may provide home care clinicians with a set of risk factors for use in targeting the patients most likely to benefit from telehomecare or other additional interventions. For example, patients who report severe pain or patients who have been hospitalized more than twice in the past 12 months may be considered high-risk patients who need an additional intervention.

Key words: heart failure, telehomecare, rehospitalization, survival analysis

Automated Detection of Transient Lower Esophageal Sphincter Relaxations

Martin Karpefors, PhD[1] & Magnus Ruth, MD, Prof (affiliated)[2]

[1] Advanced analytics Center, B&I Sciences, GMD, AstraZeneca R&D
[2] Dept of Otolaryngology, Sahlgrenska University Hospital, Gothenburg, Sweden

Abstract

A new method to automatically detect Transient Lower Esophageal Sphincter Relaxations (TLESRs) was developed using a random forest supervised machine learning algorithm. Potentially, this type of method can make fast, objective and reproducible evaluation of manometric recordings, which is a prerequisite for using TLESRs as an endpoint in large clinical trials.

Introduction

Transient Lower Esophageal Sphincter Relaxations (TLESRs) are short relaxations in the tonus of the sphincter which are triggered by gastric distension. They allow venting of air from the stomach but constitute also the main mechanism for reflux of gastric contents into the esophagus. Therefore, the number of TLESRs can be used as a marker for reflux disease.

In clinical trials, experts manually inspect recordings of esophageal pressure to identify the TLESRs according to specific TLESR criteria. Such inspections take approximately 45 minutes even for an expert. In addition, both the intra- and inter-expert variability is relatively high[1]. Consequently it is difficult to use this endpoint in larger studies.An unsuccessful earlier attempt to automate detection was made by van Herwaarden et al.[2] However, they encourage the development of new algorithms.

Method and Results

Using trial data from an internal study, we have developed a supervised machine learning classification algorithm that automatically detects TLESRs. The algorithm was based on random forest and trained on recordings from 10 subjects. All recordings were evaluated by an expert to find the TLESRs. In the training material, the expert identified 113 TLESRs and these were used as the true TLESRs. Training examples of non-TLESRs were chosen at random in the recordings, and in excess by a factor of five. During the training we had an out-of-bag error of 5.75%. However, the main challenge was to use the model on full length recordings. By applying the algorithm stepwise, in a moving window fashion along the entire recording, the probability of having a TLESR at each time point was calculated. For a probability threshold of 0.6, the result showed that the sensitivity was as high as 90% and PPV 50%.

Conclusion

Manual evaluation of TLESR is time consuming and associated with a high reader variability which has implications for the use of the technique in large clinical trials. The present study describe an algorithm for automatic detection of TLESR with the potential to speed up the evaluation process and reduce variability, thus providing a cost effective alternative to manual evaluations.

A Knowledge-Based Collaborative Clinical Case Mining Framework

Ramakanth Kavuluru, Ph.D[1], Anthony Rios, B.S[1],
Brandon Kulengowski[2], and Patrick McNamara, Ph.D[2]

[1]Division of Biomedical Informatics, Department of Biostatistics, University of Kentucky
[2]Department of Pharmaceutical Sciences, University of Kentucky

Introduction: An important challenge in developing and maintaining an effective Pharm.D curriculum is to design assessment methods that incorporate newer clinical case scenarios that model realistic situations students might encounter in their professional careers. Such scenarios often involve assessment of students' comprehension of a set of core concepts (in physiology, biochemistry, pharmacology) that interact in myriad ways to result in complex cases. Coming up with new assessment scenarios is also practically relevant in obviating the problem of students passing their test questions to future students. However, building an evolving assessment case repository based on these realistic scenarios is a highly time consuming task given there are over 2.4 million case reports and clinical trial publications indexed by PubMed. Our effort aims to expedite this process through knowledge-based collaborative methods.

Contribution: We built a collaborative clinical case mining tool that lets users search for cases based on different aspects of drugs and diseases that are the focus of a curricular component. Users can also assign tags that correspond to different core concepts of the curriculum for subsequent retrieval based on tags and named entities. We deployed an initial prototype that is being used by five researchers in the domain of bacterial infections at http://ccmining.uky.edu.

Methods: The input for the bacterial infection domain was a set of names of 50 infection causing microorganisms and 72 drugs with therapeutic relevance in the treatment of those infections. We passed each of these names through MetaMap with the *term processing* option to identify concept unique identifiers (CUIs). Next, using a disjunctive query of all synonymous English names of these CUIs from the UMLS Metathesaurus, we retrieved 215,000 citations with publication type 'case reports' or 'clinical trial' from PubMed. The disjunctive query is also run on clinical trials made available through http://clinicaltrials.gov/ which resulted in 8000 trials. We extracted all named entities using MetaMap from these two sets of documents and indexed them using Apache Solr for entity based search. Specific semantic types were chosen to restrict search based on drugs or microorganisms. Although PubMed facilitates MeSH based query expansion, here we also provide search based on named entities from title and abstract. An important set of core concepts in Pharm.D programs involves drug properties and their interactions with disease mechanisms. Hence finding cases based on properties of a drug such as drug targets, mechanisms of action, volume of distribution, solubility, and bioavailability is an important requirement for finding interesting clinical cases. However, drug properties are often not mentioned in the case reports or clinical trial descriptions although the names of the drugs are used. To overcome this, we established an indirect connection between drug properties and clinical cases based on the particular drug names mentioned in the case narratives. We noticed that even structured versions of drug databases such as DrugBank capture drug targets, mechanisms of action, and other descriptive properties using free text. Even numerical properties such as volume of distribution, solubility, and protein binding follow non-uniform notation and are essentially captured as strings. Using a set of expert selected semantic types, we extracted named entities from the target and mechanism of action text snippets in DrugBank for each of the drugs. The numerical properties were manually curated by domain experts. The drug property database thus curated was used to link properties to particular cases that employ the corresponding drugs.

Discussion and Future Enhancements: Currently the system allows users to quickly search for cases based on named entities or properties of drugs used in the cases. Users can also annotate the results with custom concept tags. Search results are displayed in a faceted browsing interface with MeSH terms and user tags as the facets. Five faculty members from the UKY College of Pharmacy are assigning tags that correspond to core concepts in their teaching activities. Future goals are to build an ontology of core concepts based on the tags, incorporate 'related cases', quality metrics (e.g., impact factors), and also expand the corpus and drugs beyond bacterial infections domain.

The Role of Big Data in Community-wide Population Healthcare Delivery and Research

Hadi Kharrazi, MD PhD[1]
[1]Johns Hopkins School of Public Health, MD

Introduction

The emergence of big data in healthcare is inevitable. The growing demand for big data has been empowered by major improvements in data sharing, steady rise of Electronic Health Record adoption, and supporting federal policies and incentives. The appetite for big data has already reached community-wide population health initiatives partly due to the recent roll out of Accountable Care Organizations (ACO). These policies and technological advancements have created a unique 'landscape' to draw upon big data for a 'greener' population health delivery system.

This viewpoint presentation attempts to expand on the challenges and opportunities that Johns Hopkins Medical Institute (JHMI), as an academic medical center, is facing to utilize existing and potential sources of big data to enhance its community-wide population health. These challenges and opportunities can be applicable to other academic medical centers in which big data will play a key role in the future of evidence-based community-wide healthcare delivery.

Methods

This presentation reviews a list of infrastructures, centers, projects, and initiatives that JHMI has established to propel the use of big data in improving the population health of their patient community. This list is then mapped against potential sources of Big Data in population health management to identify gaps and opportunities that are applicable to other academic medical centers as well. Furthermore, a conceptual framework is proposed and then contextualized for JHMI to identify stages involved in translating Big Data into effective population healthcare policies.

Direct implications of Big Data initiatives at JHMI includes the neighboring communities (i.e., surrounding zip codes) and translated through various population healthcare delivery mechanisms (e.g., Johns Hopkins Community Health Partnership and the Johns Hopkins Coordinated Antenatal Service Enhancement). Indirect implications of this review may surpass JHMI's patient communities as other academic medical centers may adapt similar Big Data population health frameworks and amend existing or potential gaps.

Results / Principal Findings

After applying the proposed conceptual big data population health framework at JHMI, the following items were identified as critical to overcome the barriers in translating big data into community-wide outcomes: (a) increasing the coordination of activities among all centers and institutes through a 'Population Health Big Data Committee' operating under the ACO management; (b) aligning incentives for participating units, centers and institutions to form a big data eco-system; and, (c) promote the culture of sharing in which population-level clinical data can be accessed and studied by researchers for the purpose of quality improvement, while research findings can be swiftly translated into population solutions and deployed back into operations.

Discussion / Conclusion

The federal government has supported the big data movement in various domains, including healthcare, through a number of policies. Federal government has also supported the culture of open data and empowered decision makers to share big data while assuring privacy and security concerns. Probably the most impactful federal policies and legislations that have spurred the use of big data in community-wide population-health are initiatives that have no direct aim at big data. Federal government can empower the use of big data for improved population health by: (a) Funding dedicated projects and/or open calls for translational population health research using big data; (2) Expanding the current funding opportunities such as CMMI to include the use of big data for community-wide population health; (3) Establish an 'Office of Big Data' with various committees, including population health, at ONC to coordinate big data efforts in healthcare; (4) Incorporating community-wide population health measures in the future stages of Meaningful Use.

States have less control on the overall big data policies; however, various healthcare delivery and payment models can change the landscape of big data in population health. For example, in Maryland, the All-Payer model and state-wide PCMH have empowered providers to work with the HIE to improve population health. Other State initiatives such as Health Enterprise Zoning and Community Integrated Medical Home can stimulate the use of big data in population health as well. Results of such big data initiatives will eventually change the outcomes of population health research in each State which in turn can potentially lead into changes in local healthcare policy, statues and regulations.

Academic medical centers have the opportunity to lead the Big Data movement in the population health domain.

Creating, Maintaining and Publishing Value Sets in the VSAC

Emir Khatipov[1], Maureen Madden[1], Pishing Chiang[1], Philip Chuang[1], Duc Nguyen[1], Ivor D'Souza[1], Rainer Winnenburg[1], Olivier Bodenreider[1], Julia Skapik[2], Rob McClure[1,2], Steve Emrick[1]

[1]National Library of Medicine (NLM®), National Institutes of Health (NIH), Bethesda, MD, USA; [2]Office of the National Coordinator for Health Information Technology (ONC), Washington, DC, USA

The Value Set Authority Center (VSAC, https://vsac.nlm.nih.gov/) is developed by the NLM in collaboration with ONC and Centers for Medicare & Medicaid Services (CMS). VSAC provides access to value sets that are used to define concepts used in clinical quality measures and to support effective health information exchange and many other biomedical informatics applications and programs. VSAC has fulfilled the immediate need for a comprehensive resource that supports the creation and maintenance of value sets used by data elements in 2014 electronic Clinical Quality Measures (eCQMs). It currently continues to expand its repository beyond the Meaningful Use (MU) domain into such areas, as Patient Assessment Instruments, Common Data Elements for research, public health, the ONC S&I Framework, and other clinical modeling efforts.

In October 2013, NLM launched the VSAC Authoring Tool that allows authors to create, edit, clone, update and publish value sets. VSAC also provides data integration with the CMS Measure Authoring Tool (MAT) via a REST Application Programming Interface (API) that uses the *Integrating the Healthcare Enterprise (IHE) Sharing Value Sets (SVS)* specification.

The VSAC Authoring Tool features the following major characteristics, functionalities and capabilities:

- Robust workflow with Authors and Stewards as major players that perform specific functions via sets of tiered permissions and check points. Essentially, Authors perform editing functions, whereas Stewards approve the work of the Authors and submit value sets for publication.
- Users can create extensional value sets, which are sets of codes and terms derived from a single code system, and grouping value sets that represent one or more extensional value sets grouped together based on a common purpose of use.
- Users can search codes, as well as value sets containing specific codes and keywords, and add those to the value sets. Codes can also be imported in batch or through manual input, in which cases the system automatically validates them and provides user feedback when it detects problems.
- Definition of value sets are captured via specific metadata elements describing purpose of use and inclusion/exclusion criteria for the values.
- Value set definition can be applied to any version of a code system in the VSAC. This process is called expansion. VSAC generates and makes available to users expansion profiles that are used to create and publish code system version-bound value sets.
- VSAC can create program-specific expansion profiles that include mandated code system versions, built-in code validation rules and lists of excepted legacy and provisional codes. These profiles are used, e.g., for packaging annual MU value set releases in support of eCQM development process.

In the future, VSAC will provide an interface for authors to create intensional value set definitions. Such definitions will contain the rules that will allow the system to automatically remove or replace values to reflect code system updates, as well as to discover new concepts that are appropriate for inclusion into value sets. This will significantly ease the maintenance burden on value set authors.

Access to VSAC requires a free Unified Medical Language System® (UMLS®) Metathesaurus License, due to usage restrictions on some of the codes contained in the value sets. To author value sets, users need to obtain permissions by contacting VSAC's Support Group (http://www.nlm.nih.gov/research/umls/support.html). To receive important VSAC announcements, users can subscribe to the VSAC Updates e-mail list (https://list.nih.gov/cgi-bin/wa.exe?A0=nlm_vsac_updates).

Acknowledgments: This work was supported in part by the Intramural Research Program of the NIH, NLM.

A Direct Query Mechanism for Exchanging Quality and Performance Measures: A Proof of Concept with California Health Plans and Physician Organizations

Katherine K. Kim, PhD, MPH, MBA[1], Brian Goodness[2], Holly C. Logan[3], MA, David A. Minch, BS, FHIMSS[4], Dolores Yanagihara, MPH[3]
[1]University of California Davis, Sacramento, CA; [2]Integrated Healthcare Association, Oakland, CA; [3]San Francisco State University, San Francisco CA; [4]Healthshare Bay Area, San Francisco, CA

Introduction: Clinical data has become a necessary foundation for enabling new models of healthcare delivery that support efficient, high quality, and patient-centered care. These data are equally important for aligning reimbursement and incentives and claims data may be inadequate for these purposes [1]. Physician organizations (POs) and health plans (HPs) have access to different types of clinical data and they need an efficient mechanism for sharing these data with their partners. Integrated Healthcare Association (IHA) which manages the statewide California pay for performance incentive program, initiated a proof of concept project (POC) to assess whether a direct query architecture could be used to automate the process of gathering and analyzing quality improvement/performance measurement data from POs and HPs periodically, when they are timely and relevant, rather than many months after the fact.

Methods: The goal of the POC was to utilize a direct query system to collect and exchange data for CMS Medicare Stars outcome measures for analyses involving two use cases: 1) Compiled measure results (numerators and denominators) from POs and HPs to IHA for the purpose of performance measurement and public reporting, and 2) Compiled patient-level data to allow tracking of individual patient status for quality improvement and provide input to the aggregated Medicare Stars quality measures, including pharmacy and readmission data from HPs to POs and laboratory, vital signs and other clinical data from POs to HPs. Two POs and two HPs participated with IHA in a five-month long POC. The Global Information Network Architecture (GINA), an advanced object-oriented data management technology solution for cross-entity interoperability on a peer-to-peer basis from Creek Technologies, Inc. was used to securely exchange data between multiple configurations of participant organizations [2, 3]. The evaluation included construction of the data model, performance testing, and exchange results.

Results: Patient-level lab results, vital signs, and prescription fills were successfully exchanged between one PO-HP pair. Test data were exchanged between other PO-HP pairs. Measures were delivered from two POs and two HPs to IHA. Key lessons were learned regarding: 1) the lengthy lead time required to build confidence in the privacy and security assurance mechanisms as well as to sign legal agreements, 2) slow performance encountered when transmitting large identified data sets due to limitations in the technology stack used, 3) improving the indexing of source databases to hasten record identification, and 4) improving system documentation and technical project management tools for larger scale rollout.

Discussion: This project was championed by executives at each organization and resources were dedicated to accomplishing it in on a very truncated schedule. We successfully demonstrated a proof of concept that the direct query infrastructure was operational, that the data model was implemented, and that verified exchange occurred between the appropriate paired partners. However, a limited number of records were exchanged. Continued effort is required to implement a fully operational and scalable system for statewide exchange that demonstrates value as a mechanism for exchanging both calculated performance measures and patient-level data for quality improvement.

Medication Prescription Status Classification in Clinical Narrative Documents

Youngjun Kim, MS[1, 3], Jennifer Garvin, PhD, MBA[2, 3], Julia Heavirland[3], Jenifer Williams[3], Stéphane M. Meystre, MD, PhD[2, 3]
[1]School of Computing, [2]Department of Biomedical Informatics, University of Utah; [3]VA Health Care System, Salt Lake City, Utah

Abstract: *Classifying what the status is of medication diagnosed for heart failure patient is one of the key tasks needed to assess whether a given patient's clinical record substantiates the proper treatment. To determine the prescription status of each medication (i.e., active, discontinued, or negative), we implemented a SVM classifier with lexical features and achieved good performance, reaching 95.49% accuracy, in a five-fold cross validation evaluation.*

Introduction: Heart Failure (HF) is a common but serious medical condition and patients with a decreased systolic function should be treated with medications such as Angiotensin Converting Enzyme Inhibitors (ACEI) or Angiotensin II Receptor Blockers (ARB) to improve symptoms and prevent progression of HF. To help assess HF treatment at the VHA (Veterans Health Administration), the ADAHF (Automating Data Acquisition for Heart Failure) project included the development of an application to automatically extract HF treatment performance measure information from clinical notes. This application (called CHIEF) included the extraction of ACEI and ARB medications, as well as the classification of their prescription status: *active* (patient currently takes the medication), *discontinued* (patient remains off the medication or is temporarily taken off the medication), and *negative* (the medication does not pertain to the patient or is negated). Such status is crucial for accurate performance measure classification.

Methods: As part of the ADAHF project, we randomly sampled 3,000 clinical notes from our training corpus. These notes were manually annotated and included 6,007 medication annotations (4,911 ACEIs and 1,096 ARBs). Among annotated medications, 4,491 (74.76%) were *active*, 1,191 (19.83%) were *discontinued*, and 325 (5.41%) were *negative*. We built a linear Support Vector Machine classifier based on earlier work by Kim and colleagues [1] with lexical features (medication name, five words preceding it, and two words following it) to automatically determine the prescription status of ACEI and ARB medications.

Results: We used a five-fold cross validation with annotated medications to measure performance of medication prescription status classification. The overall accuracy reached 95.49%. Precision of each status was above 90%, and recall of the *discontinued* status was 86.23%. Recall was higher than precision with the *negative* status, even though they corresponded to only 5.41% of the annotated medications in our corpus. A total of 230 (71 + 159) *active* or *discontinued* cases were misclassified as the other class.

Table 1. Medication prescription status classification results

	Classified as			Count	Recall (%)	Precision (%)	F_1-measure (%)
Status	Active	Discontinued	Negative				
Active	4403	71	17	4491	98.04	96.26	97.14
Discontinued	159	1027	5	1191	86.23	92.94	89.46
Negative	12	7	306	325	94.15	93.29	93.72
Overall	4574	1105	328	6007	95.49	95.49	95.49

Conclusion: Our work shows that the prescription status of each medication can be successfully classified with lexical features extracted from the words surrounding medication names. The prescription status determined by our classifier can also be used for extracting reasons not to administer ACEI or ARB medications and evaluating if HF patients have benefited from appropriate care.

Automated Phenotype Detection Facilitates Data Warehouse Analysis; an Example Using Structured Query Language and Exudative Pleural Effusion

John Kimbrough, MD, PhD[1], Vojtech Huser, MD, PhD[2], James J. Cimino, MD[1,2]
[1]National Library of Medicine, National Institutes of Health, Bethesda, MD
[2]Laboratory for Informatics Development, NIH Clinical Center, Bethesda, MD

Abstract
To explore automated screening methods that could be used in healthcare data warehouse analysis, we modelled a clinical phenotype in Structured Query Language (SQL). As a case study, diagnostic criteria for an exudative pleural effusion were used as the basis of an SQL modelled phenotype to screen a dataset of intensive care unit patients. This approach detected cases beyond those documented in provider notes, and may be incorporated into clinical decision support and similar projects.

Introduction: Data warehouses have created opportunities to pursue studies with advantages such as reduced risk and cost savings. Studies of warehouse data usually require analysis of information originally collected for another purpose, requiring the data to be screened for the condition of interest to the current project. We chose to model exudative pleural effusion because explicit diagnostic criteria are available and because identifying an effusion as an exudate suggests diagnoses such as malignancy (whereas effusions that are not exudative are more common in conditions such as heart failure). We used the Multiparameter Intelligent Monitoring in Intensive Care II (MIMIC-II)[1] database because it is accessible to external researchers and has more than 32,000 patients.
Methods: A meta-analysis that reviewed methods of pleural effusion classification reported that multiple rules were effective, but there were no overall best criteria[2]. Therefore, we used a 3-test rule supported by the meta-analysis that includes pleural fluid cholesterol, lactate dehydrogenase and protein measurement to create an SQL query that maps the rules of the test to the terms of the database. Any fluid with a lab value exceeding the test's threshold is classified an exudate. In order to evaluate our SQL-based phenotype, we created an evaluation subset of 100 randomly selected patients that had the keyword "exudate" in provider notes. We used automated review of lab results combined with manual review of provider notes to determine all true cases of exudative pleural effusions.
Preliminary Results: In the evaluation set, the manual review of provider notes detected 13 cases, recall was 81% and precision was 100%. In the same subset, the SQL phenotype detected 15 cases and was associated with a recall of 94% and a precision of 100%. The lack of a traditional gold-standard limits the interpretation of the calculations, and therefore discrepancies between automated and manual approaches were examined. There were three cases detected by the SQL phenotype that were not diagnosed in the provider notes, because these cases satisfy laboratory criteria one interpretation is the diagnosis were absent from provider notes because they were clinically missed (i.e. the provider notes had 3 false negatives). In the one case documented in provider notes and not detected by SQL phenotype, the providers based their conclusion on a serum (not pleural) laboratory result.
Discussion and Conclusions: Our approach has the advantages of automation and explicit, updatable rules. We uploaded the phenotype to PheKB (development status) to facilitate cross-institutional sharing. The motivation for our study was to demonstrate feasibility of clinician-authored SQL phenotypes. This approach may be used in circumstances beyond clinical studies such as responding to drug safety alerts. As newly discovered issues, these alerts often address problems not included in previous encounters, confounding searches that rely on provider note content. Manual review may lack the efficiency desirable in responding to a safety alert. These warnings often include a succinct list of explicit concerns, and therefore may be potentially adapted into queries that screen coded information in a relation database. Approaches such as the SQL phenotype we wrote may also serve as triggers for clinical decision support, quality studies and screening for point-of-care enrollment in clinical trials.

Identification of Inflammatory Bowel Disease Patients with Steroid-induced Diabetes Mellitus Using an Electronic Health Record

Sivan Kinberg, MD, Lyudmila Ena, MA, Herbert Chase, MD, Carol Friedman, PhD
Department of Biomedical Informatics, Columbia University, New York, NY

Abstract

Glucocorticoid toxicity is one of the most common causes of iatrogenic illness associated with chronic inflammatory diseases, such as inflammatory bowel disease (IBD). The aim of this study was to use an informatics approach to determine the prevalence of and risk factors for steroid-induced diabetes mellitus (S-DM) and steroid-induced prediabetes (S-PDM) in patients with IBD.

Introduction

Glucocorticoids are commonly used to treat patients with IBD, often for prolonged periods of time. Although glucocorticoids have potent anti-inflammatory effects, they have been implicated in the development of S-DM and hyperglycemia in patients with various conditions.[1] Hyperglycemia, even transient, has been associated with adverse events.[2] Conversely, control of hyperglycemia during acute illness has been associated with improved outcomes.[3] Despite this, S-DM and S-PDM are often under-diagnosed and under-treated. In patients with IBD, the current knowledge of S-DM and S-PDM is limited. Using automated extraction of data in the electronic health record (EHR), we determined the prevalence of and risk factors for S-DM and S-PDM in patients with IBD.

Methods

This was a retrospective cohort study that examined patients with IBD who were treated with glucocorticoids between 2004 and 2012, excluding patients with pre-existing diabetes mellitus. Notes from the EHR were parsed using a natural language processing system[4] to encode the information, and the coded output was stored in a structured database where the relevant data were queried. We identified patients with IBD based on the intersection of ICD-9 codes and coded information from the notes. The diagnoses of S-DM and S-PDM were based on ICD-9 codes and on laboratory data consistent with the American Diabetes Association diagnostic criteria.[5] Patients with IBD treated with glucocorticoids were compared with IBD patients who never received glucocorticoids.

Results

A total of 1,719 patients with IBD were identified based on the intersection of ICD-9 codes and coded information in the notes, compared with 7,126 patients based only on ICD-9 codes and 10,812 patients based only on the notes. We found that 140 (20.1%) of 698 patients with IBD treated with glucocorticoids developed S-DM compared with 21 (5.8%) of 363 patients not treated with glucocorticoids (OR=7.42, 95% CI: 4.41-12.48). Prediabetes was identified in 192 (27.5%) IBD patients treated with glucocorticoids and in 67 (18.5%) patients not treated with glucocorticoids (OR=2.25, 95% CI: 1.59-3.17). Multivariable analysis determined increasing age, obesity and parenteral nutrition as risk factors for S-DM, and male sex and parenteral nutrition as risk factors for S-PDM.

Discussion and Conclusion

To our knowledge, this is the first study to determine the prevalence of and risk factors for S-DM and S-PDM in patients with IBD. Determining which patients had IBD was challenging. Initial manual review of patients identified based only on ICD-9 codes or only on coded information in the notes showed that some were inaccurate. Therefore, in order to increase precision, we identified IBD patients based on the intersection of ICD-9 codes and codes from the notes. We found that patients treated with glucocorticoids were 7.42 times more likely to develop diabetes mellitus and 2.25 times more likely to develop prediabetes than patients treated with non-glucocorticoids. Using the EHR for automated detection of high-risk patients is possible and could result in earlier diagnosis, timelier treatment, and possibly improved outcomes.

User Experiences of Speech Recognition Technology (SRT) by Physicians: A cross-sectional survey study

Joshua L. King, MHA[1], Martina A. Clarke, M.S.[2], Min Soon Kim, PhD[1, 2]
[1]Department of Health Management and Informatics, University of Missouri, Columbia, MO;
[2]Informatics Institute, University of Missouri, Columbia, MO

Abstract

In order to evaluate the user experience and utilization of speech recognition technology (SRT) by physicians for medical documentation, 71 physicians, in two Missouri hospitals, completed a 10 item survey, followed by an in-depth interview with a CMO. Survey on user experience showed 42 (59%) of participants experienced spelling and grammatical errors and 15 (21%) encountered clinical inaccuracy. CMO agreed that SRT somewhat disrupts clinical workflow and produced many errors that needed to be addressed.

Introduction

SRT implementations have been being actively sought after by healthcare organizations for reduced report turnaround time and financial savings. However, it will not be an effective tool if the reports created by SRT are inaccurate, poorly organized, or untimely. The objective of this project is to evaluate the user experience and utilization of (SRT) by physicians for medical documentation in two hospitals in Missouri.

Method

A quantitative survey tool was utilized to collect data related to a physician's area of practice, electronic equipment utilized for documentation created after providing care and overall experience and satisfaction of SRT. The sample of physicians was selected from one urban and one rural, tertiary care hospitals because of the institutions' pro-active adoption of SRT and willingness to participate in the study. In addition, a qualitative in-depth interview was conducted with a Chief Medical Officer (CMO) to discuss issues in implementation, training, choice of SRT, and perspective outcome from leader's perspective.

Results

Seventy-one (60%) of the anticipated 125 surveys were returned. Sixteen (23%) of participants were involved in Internal Medicine, 9 (13%) in Family Medicine and the additional 46 (64%) were spread throughout many varying specialties in medical practice. Fifty-six (79%) of participants utilized a desktop and 14 (20%) used a laptop. Windows operating system was utilized by more than 58 (82%) of the survey respondents. Nuance (Burlington, MA) products are the dominant brand, providing continuous SRT that is utilized by the participants with 59 (83%). With regard to user experience, 42 (59%) of participants experienced spelling and gramatical errors and 15 (21%) encountered clinical inaccuracy, which could potentially affect patient care. Accuracy is defined as the percentage of correct transcription;if user needs are not met in a timely manner, overall user satisfaction may decline as a result. When physicians were asked how satisfied they were with SRT, some respondents were satisfied 34 (48%) rather than dissatisfied 20 (28%) with SRT overall.

Recommendations made by participants on improving user experience include: 11 (15%) better interpretation of the spoken word, such as, foreign accent, unusual words, etc.; 9 (13%) wanted improved SRT speed because they found SRT to be too slow; 8 (11%) desired improved accuracy; 7 (10%) needed more extensive training of the system, such as voice training. During a qualitative interview with the CMO, he commented on issues in implementation, training, choice of SRT, and perspective outcome from leader's perspective. He noted that current SRT was somewhat disruptive to the clinical workflow and produces many errors that need to be addressed. The CMO finally suggested from the leader's perspective that , although not perfect, SRT has a potential for succesful and economical electronic record keeping when and if the performance of products is improved to achieve reliable service.

Conclusion

Even though SRT is used in healthcare settings to assist in the completion of medical record documentation, this study identified critical issues of inconsistency, unreliability, and dissatisfaction in functionality and usability of SRT. Although SRT has yet to reach the accuracy rate desired by physicians, it is a promising system that could potentially improve the clinical workflow by supporting the efficient creation of EHR documentation. Additionally, future use of SRT will be impacted by the ability to improve accessibility through integration into mobile platforms. Limitations of this study include a small sample size in two hospitals which limits transferability, which merit further attention be provided to the improvement of SRT's functionality and usability within varying healthcare settings.

Enabling Patient-Centric Comparative Effectiveness Research in i2b2

Jeffrey G. Klann, PhD[1,2,3]; Lori C. Phillips, MS[1]; Kenneth D. Mandl, MD, MPH[2,4]; Shawn N. Murphy, MD, PhD[1,2,3]

[1]Partners Healthcare, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Massachusetts General Hospital, Boston, MA; [4]Boston Children's Hospital, Boston, MA

Background - Informatics for Integrating Biology and the Bedside (i2b2) is an open-source clinical data warehousing and analytics platform funded by the National Institutes of Health. [1] It is used at over 100 sites nationwide, and multiple federated networks exist across i2b2-equipped institutions. It is also used by a third of the sites in the Patient Centered Outcomes Research Institute's Patient-Centered Clinical Research Network (PCORnet). PCORnet is a national effort to instantiate a national 'network of networks' that supports large-scale comparative effectiveness research. [2]

i2b2 uses a flexible database schema and user-defined information models, designed to create minimal friction for implementers when importing data from various sources. However, this flexibility impedes interoperability; exchange of data across i2b2 sites and across PCORnet networks requires agreement on an information model. PCORI envisions a highly interoperable network that will enable nationwide disease surveillance and data exchange between networks.

Therefore we have developed an approach for creating standardized i2b2 Information Models and mapping local data to them, all using existing ontology services in the i2b2 system. Our approach complements the existing i2b2 networking system (the Shared Health Research Information Network - SHRINE) [3], and we have implemented our PCORnet network's SHRINE with this new approach. Additionally, we have developed a tool to physically transform conformant i2b2 instances into the schema structure PCORnet requires for cross-network queries. More information and the tools themselves will be made available through our network's blog. [4]

System Description – We developed a common i2b2 ontology (Information Model) that instantiates the PCORnet Common Data Model. To map local data to this common ontology, we relied on two insights about i2b2's design. First, i2b2 ontology elements define both a unique pathname (e.g., \\PCORNET\DIAGNOSIS\DX\09\250\) and a unique code (e.g., ICD9:250). Pathnames are consistent across all implementations, but the codes are allowed to vary to match local data. Second, i2b2's query approach automatically includes ontology elements' children, so additional local codes can be included as children of a standard term and are automatically gathered when querying standard codes. We updated our mapping tools to support this approach. Our sites have successfully used these tools to map their data, and we have validated their correctness through comparisons of query results to database content.

To transform data into the PCORnet data format, information from the path is used to determine the destination location (e.g., table DIAGNOSIS, column DX) and 'virtual queries' are performed to populate the target database.

Discussion – This i2b2 mapping approach enables the popular i2b2 clinical data analytics platform to support standard, interoperable information models without altering the local data. We are using this at the sites in our PCORnet network to enable information exchange and comparative effectiveness research, and it will soon be used to create data marts in the PCORnet schema format for nationwide research. In the future, we hope to extend our tools to support transformation of i2b2 data into other standard formats for exchange with patients and other PCORnet networks.

Electronic Pharmacovigilance: Calling for Earlier Detection of Adverse Reactions (CEDAR)

Elissa V. Klinger, SM[1], Alejandra Salazar, PharmD[1], Japneet Kwatra, SM[1], Jeffrey Medoff, BS[1], Patricia Dykes, RN[1], Jennifer S. Haas, MD, MSPH[1,2], Mary Amato, PharmD[1], David W. Bates, MD, MS[1,2], Gordon Schiff, MD[1,2]

[1]Divison of General Internal Medicine and Primary Care, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School

Introduction: The safe and effective use of prescription drugs in the outpatient setting is an ongoing concern that may be monitored by the development of novel automated approaches to obtain patient self-reported outcome information related to potential adverse drug reactions (ADRs) and respond to these concerns in real-time. To address the growing importance of integrating information about safety and effectiveness we developed a patient-reported, EHR-integrated interactive voice response system (IVRS) to actively monitor the safety and effectiveness of treatment for patients taking FDA-approved medications for one of four common chronic conditions (diabetes, hypertension, insomnia, depression), with integrated management support by a clinical pharmacist.

Methods: Using an integrated EHR we developed an algorithm to identify any adult primary care patient at one of 9 participating clinics who had been started on an oral agent of interest within the previous 2 weeks. All eligible patients were sent a letter with study information and an opportunity to opt-out of participation. Using automated IVRS phone calls, patients were called 4-6 weeks and again at 6-8 months following their medication start date and prompted to confirm that they were taking the drug and that it was prescribed for the condition of interest. A broad screen and then targeted questions documented both adherence and symptoms commonly associated with ADRs. Any patient with a positive symptom was transferred to a pharmacist in real-time at the conclusion of the data-capture call; these data fired a real-time alert to the pharmacist containing relevant clinical information including possible ADR and pre-populated a database to drive and document the intervention. Patients reporting no symptoms could also opt to speak with the pharmacist in real-time or at their convenience. Any patient counseled by the pharmacist had a note filed in the EHR, with more urgent clinical concerns triaged accordingly.

Results: IVRS calls began in June 2013. To date we have identified and called 2,810 eligible patients prescribed one of 103 target medications. Of these, 414 (14.7%) have participated in the IVRS interviews, 228 (8.1%) have actively declined participation, 1464 (52.1%) have answered but not completed the call, and 704 (25.1%) have not answered any call attempt. Of those participating (n=414), 143 patients (5.1% of all patients called and 34.5% of patients participating in the screening) have reported symptoms consistent with ADRs and 231 (8.2% of all patients called) have completed successful transfers to the pharmacist and had notes filed in their charts and their PCPs alerted accordingly.

Discussion: We demonstrate that an EHR-integrated IVRS that leverages real-time data capture and live transfer to a pharmacist can be an effective tool to reach out in a proactive manner to patients starting new medications. Such a system allows a pharmacist to simultaneously access the EHR and speak with a patient to troubleshoot symptoms that may be consistent with ADRs, and to alert the care team in real time about possible clinical symptoms that may necessitate a change in dosage or a drug discontinuation. For patients not experiencing symptoms, the platform may provide a service to individuals who have questions about their medications or struggle with adherence.

Relating Health Concerns and Goals in Interprofessional Care Planning

Stephanie Klinkenberg-Ramirez[1], Kira Tsivkin[1], Perry L. Mar, PhD[1,2,3], Hari Nandigam MD, MSHI[1], Dina Iskhakova[1], Roberto A. Rocha MD, PhD[1,2,3], Sarah Collins, RN, PhD[1,2,3]

[1]Partners Healthcare System, Wellesley, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA

Abstract

Coordinated care planning is associated with better patient outcomes. We investigate how interprofessional care planning can move from indexing to associating clinical concepts salient for care planning across the continuum of care and between health professions. This work evaluates terminology management approaches and a conceptual schema for interprofessional care planning by developing and validating clinical care planning scenarios with subject matter experts. We identified "goals" as a terminology construct commonly used among clinicians.

Introduction

Team-based care planning requires individual team members to establish common ground and goals with each other to reconcile their respective plans of care and treatment plans into one patient-centered care plan. This reconciliation of plans is challenging to achieve via shared documentation tools used by multiple clinical professions because of their distinct and overlapping terminology needs.[1] Goals are inconsistently documented and lack linkages indicating relations to each other. The aim of this poster is to understand the common care planning concepts and their associations, with a particular focus on goals that may be leveraged for care planning reconciliation by analyzing 4 clinical scenarios validated by a set of health professionals that work as a team in an outpatient setting.

Methods

We developed four clinical scenarios for the outpatient setting, representing care for patients with the following conditions: uncontrolled diabetes mellitus type I, congestive heart failure related to myocardial infarction, diabetes mellitus type II and uncontrolled depression, and immune-mediated kidney failure. Clinical scenarios contained assessment data, past medical history, and health concerns, interventions and goals identified by a physician, care coordinator, social worker and pharmacist. We conducted individual 1-1.5 hour interviews with subject matter experts, including a primary care physician, two care coordinators, a psychiatrist, and a pharmacist, during which they validated the scenarios for clinical accuracy with emphasis on care planning concepts. Requirements for a corresponding conceptual model and terminology needs were identified.

Results

Health professionals identified distinct concerns and interventions related to their profession or specialty area. For example, the physician identified the concern of major depressive disorder and prescribed antidepressants and a referral to a social worker. The social worker's concerns included inadequate social support and requested a referral to psychotherapy. Within the team, individuals communicated to facilitate interventions identified by another clinician. For a patient struggling with adherence, the pharmacist recommended a new diabetes medication regimen for the physician to prescribe. Despite identification of distinct concerns and interventions, the health professionals identified common goals for the clinical scenarios that were either synonyms or hierarchically related as goals and sub-goals (see Figure 1). An information model was constructed to support goals and their relationships.

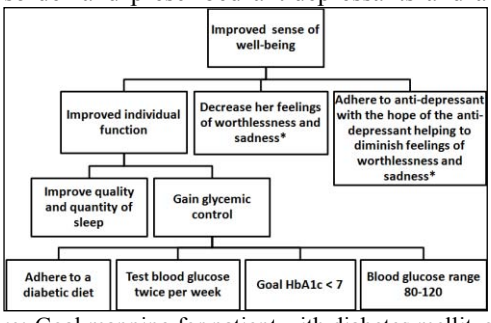

Figure: Goal mapping for patient with diabetes mellitus and uncontrolled depression. *synonymous goals from different clinical professions.

Conclusion

Our data indicate that related goals are a common construct for care planning in a team of health professionals who identify similar concerns and execute related interventions. Further work should validate this observation in other care settings and clinical scenarios and investigate how to link goals to concerns and interventions.

Barriers and Benefits to CHT Use in Overweight and Obese Adolescents

Amy Knoblock-Hahn, Ph.D[1], Cynthia LeRouge, Ph.D[1], Shashank Jain[1], Kate Dickhut[1], Toree Malasanos, M.D.[2]
[1]Saint Louis University, St. Louis, MO; [2]Vheda Health, Baltimore, MD

Abstract

Adolescent overweight and obesity is a major public health concern, with many long-term implications for patients and the healthcare system. Consumer health technology (CHT) has the potential to support adolescents in their efforts to achieve and maintain a healthy weight. However, barriers and benefits to use of CHT must be addressed in the design of CHT, in order for the technology to actually be adopted by adolescents.

Introduction

Overweight and obesity in children and adolescents has reached an all-time high in the United States[1]. Multiple levels of influence from the socio-ecological model manifested in the Chronic Care Model (CCM) are thought to contribute to the increased prevalence of adolescent obesity. CHT tools may help close identified gaps in the socio-ecological ideal, but research in the use of CHT for obesity management in adolescent populations is lacking. The objective of this study is to examine the potential barriers and benefits to overweight and obese adolescents using CHT to self manage their condition within the context of existing CCM components.

Methods

A qualitative, multi-perspective, non-randomized research method was used. Focus groups and in-depth interviews with overweight and obese adolescents, pediatricians, and parents of overweight and obese adolescents were performed. The Unified Theory of Acceptance and Use of Technology (UTAUT) was applied as a means to categorize barriers and facilitators; the UTAUT model has been shown to account for 70% of the variance in intention to use technology[2].

Results

Adolescents, parents, and pediatricians expressed intent to co-use CHT applications. Primary barriers and facilitators to the use of CHT applications in overweight and obese adolescents were identified (Table 1).

Table 1: Intent to Use Adolescent Obesity Self-Management Applications by User Group

Construct	Barriers/Facilitators		Adolescent	Parent	Provider
Performance Expectancy	Food records & track physical activity	Facilitator	X	X	
	Meal planning & Portion Size Guidance	Facilitator	X	X	X
	Security/Privacy	Barrier		X	
Effort Expectancy	User-friendliness	Facilitator	X	X	
	Design optimized for adolescents needs	Facilitator	X		X
	Time constraints	Barrier	X		
Social Influence	Peer Networking	Facilitator	X		
Facilitating Conditions	Information on healthy behaviors	Facilitator	X		
	Multiple Technology Platforms	Facilitator	X	X	X

Conclusion

CHT tools for adolescent obesity self-management may help close identified gaps in ongoing treatment for obesity, but various barriers and facilitators need to be addressed for CHT to be effective.

Designing clinical models of EHR (Electronic Health Records) for long-term care providers to elderly persons

Shinji KOBAYASHI, MD, PhD[1], Naoto KUME, PhD[1], Tomohiro KURODA, PhD[2], Hiroyuki YOSHIHARA, MD, PhD[1]
[1]EHR Research Unit, Kyoto University, [2]Division of Medical Information Technology and Administration Planning

Abstract

Clinical information management for elderly people involves various stakeholders in local community, and sharing it among them is proposed as a promising way. We analyzed and designed standard XML formalism based on openEHR clinical archetypes models and MML (Medical Markup Language) to construct integrated EHR.

Introduction

To manage long-term care for elderly persons is one of the emerging issues in aging countries. Because elderly person tends to have multiple physical/social dysfunctions, they need various services mainly in health care for their lives. Sharing information among caregivers is considered as an effective way, so that we examined over our existing EHR implementation, and standardized information model were able to apply for this purpose. However, our EHR was targeted for mainly for hospitals/clinics in regional health care. We need to extend our EHR and standardize information models for long term care for elderly persons.

Methods

We had discussed the use cases with care providers and figured out it on mindmaps. The figured mindmap revealed that use cases had much diversity and included complexed information models. After we explored our development schedule of EHR and the priority, we determined to standardize flow sheet in daily care. While we review over flow sheet information model, vital sign needed to be a separated particle to utilize other modules. Flow sheet module was composed with four categorized items, such as 1) vital sign, 2), intake, 3) bodily output, 4) personal demographics. And the next step, we defined W3C XML schemas[1] on existing base, such as MML(Medical Markup Language)[2] and other health care standards. The openEHR clinical knowledge manager was helpful to examine clinical concepts[3]. During these processes we had implemented a sample application to show how they worked.

Results

Flow sheet and vital sign clinical information models had been published as candidates of official release as additional modules of MML. The models will be established as new modules in 2014. A group of care providers adopted these modules experimentally to their care houses. While discussion has been going on still now, we are implementing EHR modules for long-term care providers on existing regional EHR system. The open source development process has been helpful for discussion in detail, because we could prove the behavior of artefacts at the same time. However, we need more information models to implement EHR system for elderly persons. Evaluation for activity and dysfunction in daily life is a next problem, but the evaluation standards, such as WHO ICF include many subjective items hard to implement computational/interoperable metrics. More discussion with nursing professionals will be needed.

Conclusion

We had designed standard information modules for long-term care providers to elderly persons. For their use case, to record vital sign and daily flow-sheet are important. To make standard information model, mindmap and sample application were helpful to discuss on them. More clinical models need to be designed to evaluate activity or dysfunction of person in the next step for long term care EHR.

Abstract

We propose a general propensity matching algorithm to accommodate multiple outcomes observed in Outcomes Miner, a comparative analytics solution for observational studies. We categorized the approximately fifty available outcomes into groups of similar overarching concepts and used Maximal Information Coefficient to identify the variables most closely correlated with each group. After consolidating the variables across outcome groups, stepwise regression identified the final set of variables used for the propensity calculation.

Introduction

Outcomes Miner is a real world evidence-based solution that provides the user with observational study data in the form of a series of integrated and interactive reports that generate detailed insights and qualified hypotheses from comparative clinical studies. Users can explore hundreds of demographic and health-related variables and sub-groups based on those variables and their relationships to 50 previously established outcomes. One limitation is that, as with manually curated observational studies, the Outcomes Miner may also suffer from confounder bias. The typical solution to address this limitation is to develop a propensity matching algorithm, which equally distributes potential confounders across the treatment arms. To account for this limitation in the Outcomes Miner research platform, we propose a propensity matching algorithm that is developed and programmed into the research platform.

Methods

To develop the propensity matching algorithm, first, we sorted the 50 possible outcomes into five groups: “mortality outcomes,” “health system utilization outcomes,” “disease-specific health system utilization outcomes,” “laboratory biomarker outcomes,” and “clinical outcomes.” We selected a subset of outcomes from each group (e.g. number of emergency room visits from the health system utilization outcomes group), and we used MIC (Maximal Information Coefficient) to identify the 20 variables most highly correlated with each outcome from each group. Those 20 variables identified for each group were then consolidated into a single regression model. In turn, the single regression model was performed against the outcomes to identify the set of variables associated with the majority of outcomes, which are used in the final propensity model.

Discussion

With the availability of over 300 independent variables in the Outcomes Miner, the above-described propensity matching method produces a more robust algorithm that will more accurately distribute confounders across treatment groups while still taking into account the multiple outcomes of interest. Additionally, this approach takes into account unique relationships between variables and outcomes within the patient population. While the Outcomes Miner platform provides the end user with the ability to analyze up to 50 outcomes in a comparison study across a wide variety of sub-groups, the propensity matching algorithm remains constant regardless of the outcome considered. For the initial tests on the Outcomes Miner reports, we focused efforts on applying the platform to the clinical realm of diabetes. We established a first round propensity matching algorithm with 15 variables identified in the literature as associated with general morbidity and mortality for diabetes, which we have replaced with the above-described model.

Development of an Automated Cirrhosis-Associated Symptom/Finding Detection Tool

Jejo Koola[1,2], Robert Cronin[2], Ruth Reeves[1], Jason Denton[1] Samuel B. Ho[3,4], Michael Matheny[1,2]
[1]Tennessee Valley Healthcare System, Dept. of Veterans Affairs, Nashville, TN
[2]Vanderbilt University, Nashville, TN
[3] VA San Diego Healthcare System, San Diego, CA
[4] University Of California San Diego, San Diego, CA

Introduction

Chronic liver disease, whose prevalence reached 15% in the United States, causes 44,000 deaths annually. Despite emphasis on early detection and guideline appropriate management, twenty percent of cirrhotic patients are not identified until late complications occur. When advanced disease was identified, patients only receive 30-90% of guideline recommended measures. Informatics solutions, which may improve cirrhosis care, rely on structured data. Unstructured aspects, such as homelessness, alcohol use and psychiatric problems, are known to inform liver disease progression, but studies which incorporate them invariably use hand-curated records. This study pilots annotation of a cirrhosis document corpus.

Methods

We obtained 60 gastroenterology History and Physical (H&P) from a patient cohort hospitalized at the Dept. of Veterans Affairs (VA) MidSouth Health Network anytime between 2002 and 2011. Two physicians, with a third acting as an adjudicator, identified clinical characteristics known to be correlated with cirrhosis: hepatitis, alcohol abuse, drug abuse, marginal housing and homelessness, encephalopathy, ascites, palmar erythema, spider nevi, jaundice, hepatomegaly, splenomegaly, firm or nodular liver, and caput medusa. Additionally, annotators marked whether the document stated anything about cirrhosis itself. Annotators also marked level of assertion (positive, negative, and maybe) and time course of finding (past or present). We report prevalence of these features in our corpus and Inter-annotator Agreement.

In order to estimate information density for an information retrieval task, we used Yale cTAKES EXtension (yTEX version 0.8 using cTAKES version 2.5.0) to perform automated concept-level annotation and generate a collection of concept unique identifiers (CUI), mapped to the Unified Medical Language System (UMLS).

Results and Discussion

The prevalence of clinical characteristics within this document corpus ranged from 0.00 to 0.60. Three concepts (nodular liver, caput medusae, and spider nevi) were not identified. Clinicians most commonly documented presence or absence of organomegaly (0.43), encephalopathy (0.60), and social risk factors (0.37 for drug abuse and 0.25 for alcohol). Because only three of the notes came from patients with advanced liver disease, we are limited on identifying relevant physical exam findings. Though the VA strives to assist veterans with substance abuse issues, the corpus poorly documents alcohol and drug use. Cohen's Kappa ranged between 0.7 and 1.0 for most of the concepts. "Marginal Housing" served as the notable exception, with a Kappa of 0.3. Given the low prevalence of the target classes, simple percent agreement (which was > 95%) maybe more indicative than Cohen's Kappa. Processing with yTEX generated 8206 CUIs across the sixty documents. Of these, 1648 were distinct.

Several opportunities exist for improvement. First, we will need to enrich the document corpus with more clinical notes from cirrhotic patients. Second, CUIs overlap significantly. We are researching dimension reduction measures to cull redundant concepts. Nevertheless, this pilot suggests that key cirrhosis related concepts can be reliably identified within a clinical corpus.

Getting Past 10%: Employing a Successful Bar Code Environment for Patient Safety

Terese Kornet, MSN, RN; Denise Gilanelli, MSN, RN; Sean R Sarles, BA, BSN, RN, CCRN; David Stabile, MSN, RN; Gregory Watson, CPhT; Colleen Mallozzi BSN, RN, BSIS; Paul Miranda RPh, MBA; Michael Motto, MBA; Nishaminy Kasbekar, BS, PharmD, FASHP

Description

Our health system piloted a multi-hospital Bar Code Medication Administration (BCMA) project using our existing electronic medical record. Multiple disciplines, including Nursing, Respiratory Therapy, Pharmacy, and Information Services collaborated to create new workflows and training structures to support the BCMA project. The pilot project was deemed a success and plans to go 'enterprise-wide' were launched within months of the initial BCMA go-live.

Penn Medicine implemented BCMA as part of an initiative to meet Meaningful Use core measure requirements. The Meaningful Use (MU) Stage 2 objective is to "Automatically Track medications from order to administration using assistive technologies in conjunction with an electronic medication administration record" (CMS, 2012); however, only looking at the BCMA process in terms of MU requirements undermines the importance of patient safety as the primary motivator for implementing this technology. The multidisciplinary collaboration of the project team was the deciding factor in the successful implementation of BCMA.

Background

- Early studies quantified the extent to which errors occur at each of the stages of the medication-use process; one of the most troubling steps in the process is the administration phase, when 26% to 38% of the errors occur.[1]
- Further, it has been described that errors at the administration phase are likely to reach the patient since there are few safeguards in place to intercept the error before it is passed onto the patient. [2]
- A recent published study by Eric Poon and his colleagues at Brigham and Women's Hospital demonstrated a 41.4% relative reduction in medication administration errors using BCMA system. [3]
- Knowing that a systematic process has been put into place to ensure patients are getting the right medication, at the right time, in the right dose, and by the right route has resulted in more positive survey results from staff, patients and patient families. [4]

BCMA in Practice

Basic Steps:

1. **Scan** the 'pairing' bar code near the keyboard
2. Sign into SCM and enter the eMAR
3. Click on the <Bar Code> icon
4. **Scan** patient wristband
5. **Scan** medications
6. Acknowledge any alerts, document site, rate/dose, etc.
7. Click <Scan Complete>
8. Administer Medications
9. Click <Medications Given> to chart the meds

Collaboration

Nursing • RT • Pharmacy • Information Services

- Nursing Informatics incorporated education and ownership to change the perception of what was initially feared as being a difficult and invasive process; through this guidance each pilot unit was able to adhere to the workflow and attain high success rates.
- Pharmacy pre-emptively designed workflow changes and adapted quickly; through careful barcode and order management, problems were resolved to streamline the process with patient care.
- Information Services managed hardware ordering, configuration and logistics; process and workflow education was provided to all roles. End user support teams at each hospital were provided with configuration and troubleshooting materials to allow ownership and ongoing maintenance to be readily accepted by each participating hospital.

Nursing Acceptance

New workflows • New software • New devices

Training
- Hands on user education performed either in a classroom setting or in a hospital room with real medications (when possible.) The goal was to create a simulated environment so nurses and respiratory therapists felt comfortable with the new process prior to using BCMA on a real patient.
- The didactic portion of the training included a strong emphasis on *patient safety*.

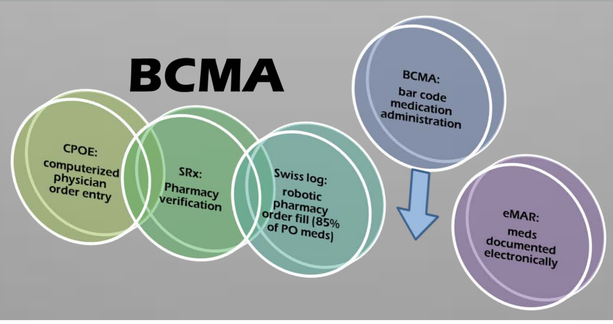
Go-live support
- Command center available on site 24 hours for the first week.

Visible Super-users
- Nursing representatives worked as super-users on their home unit.
- Resource nursing pool provided super-users, which were available for multiple units.

Daily Huddles performed
- All staff on the unit were kept informed about successful scan rates, workflow changes, and the availability of help from super-users or the command center.

Leadership participation
- Enthusiasm and visibility went a long way to drive nursing acceptance.
- Respiratory Therapy leadership's involvement improved the compliance of respiratory medications administered using BCMA.

Competency created by nursing professional development specialists.
- Competency was assessed and signed-off by nurse educators and clinical nurse specialists observing the medication administration process using BCMA.



Lessons Learned

Site visits of hospitals with the same EHR and similar hardware gave insight into workflow, potential challenges, and solutions. Based on site visits we:
- Selected bar code scanners without handles so they could be carried easily.
- Kept providers and hospital leadership 'in-the-loop' regarding the new process for medication administration.
- Set the expectation that medication administration will take longer initially.

Bar code scanning does not replace the need to do your usual safety checks.
- Must still identify the patient using two unique identifiers
- Verbally engage the patient regarding medications to be administered and any education needed.

Anticipate workarounds; especially when barcodes are available un-affixed to medication or patient wristbands. Review patient banding policy and create unique patient wristband barcodes if possible.

Design Override Reports to address non-compliant users, trouble meds, and other issues.

Communicate proper cleaning procedures for the bar code scanner hardware as these units will need to be cleaned between each (isolation) patient.

Back-up computer workstation (WOW) suggested for use when in-room devices are down.

Ongoing evaluation required to address workarounds and maintain a consistently high successful scan rate. Data sources for BCMA evaluation can include any of the following:

Nursing feedback	Override reasons
System and processes	Encourage self-report of near-misses

Outcomes

- Within several days, some locations had provided examples of what would be considered "near misses"-incorrect medications or dosages not on the patient's profile.
- Through successful adoption by each entity's pilot units, combined with the inherent patient safety value of the project, the decision was made to bring the entire enterprise up on BCMA by mid-2014.

Successful scan rate: 93% (by medication)

Reduction in Medication Errors

An Agent-based Reasoning Scheme for Prioritizing Evidence Obtained from Multiple Pharmacovigilance Signal Detection Methods

Vassilis G. Koutkias, PhD[1] and Marie-Christine Jaulent, PhD[1]
[1]INSERM, U1142, LIMICS, F-75006, Paris, France; Sorbonne Universités, UPMC Univ Paris 06, UMR_S 1142, LIMICS, F-75006, Paris, France; Université Paris 13, Sorbonne Paris Cité, LIMICS, (UMR_S 1142), F-93430, Villetaneuse, France

Abstract

We develop a multiagent system capable of exploring evidence from multiple pharmacovigilance signal detection methods and data sources. Via task distribution among its agents and an appropriate interaction protocol for their coordination, the system launches diverse signal detection method implementations, filters the aggregated results with respect to novelty, and prioritizes the remaining novel indications according to various significance criteria.

Introduction & Background

Accurate and timely signal detection is a major challenge in pharmacovigilance. While diverse methods and data sources are employed for this task, current efforts illustrate bias, high false-positive rates and other limitations. In this respect, it has been argued (with supporting evidence[1]) that signal detection may be leveraged through integrated approaches. In this work, we employ the agent paradigm[2] to design a reasoning strategy that will support combinatorial signal detection using diverse detection methods and drug safety resources for filtering.

Methods

We consider detection methods suitable for observational data, spontaneous reports and free-text sources. Software agents offer an important metaphor to address problems of incomplete and distributed knowledge[2]. Delegating simple-specific tasks to agents and coordinating their actions through an agent interaction protocol enables us to: (a) launch signal detectors and aggregate their outcomes, (b) filter the results obtained with respect to known adverse drug reactions using reference sources, and (c) prioritize the remaining novel signals based on their significance. For prioritization, two types of criteria are employed: (a) computational metrics that are commonly used in the field of information retrieval, e.g. precision at *k*, and (b) domain criteria that have been proposed for implementing triage schemas for signal detection, e.g. ADR seriousness, rapidly increasing disproportionality, newer drug, etc.

Results

Our development relies on signal detection methods that are available in the PhViD R package (http://cran.r-project.org/web/packages/PhViD/) and drug safety sources like SIDER (http://sideeffects.embl.de/). For agent development and execution we use JADE (http://jade.tilab.com/). We design classes of agents according to the described tasks and work on a voting scheme to enable prioritization by combining the above ranking criteria. Agent coordination is based on message exchanges encoded in FIPA ACL (http://www.fipa.org/repository/aclspecs.html).

Discussion

We conceive signal detection within an integrative setting that accounts for multiple heterogeneous data sources and multiple detection methods. To this end, we adopt technologies like software agents and knowledge engineering[3] for the development of an integrated platform to contribute in accurate and timely signal detection.

Development of an Interactive, Spatial, Web-Based Tool for Physician Workforce Planning, Recruitment, and Research

Denise D. Krause, Ph.D. [1,2], John R. Mitchell, M.D.[2], Diane K. Beebe, M.D.[1]
[1]University of Mississippi Medical Center
[2]Office of Mississippi Physician Workforce

Objective. To develop a web-based, interactive physician workforce surveillance application for the Office of Mississippi Physician Workforce (OMPW) using geographic information systems (GIS) to serve as a tool for effective workforce planning, recruitment, and health services research, to improve access to health care.

Methods. The Mississippi Board of Medical Licensure provided individual level licensure data on all active physicians practicing in the state to provide a cross-sectional view of the physician workforce. This dataset includes, but is not limited to, date of birth, gender, race, specialty, and school of graduation. From these and publicly available data from the U.S. Bureau of Census, we calculated physician-to-population ratios by county for each year of the last decade and median family income by county in order to gain an historical perspective of the demographics and distribution of the physician workforce. Data on health professional shortage areas were obtained from the Health Resources and Services Administration's website. ArcGIS Online and ESRI's geo-enrichment services supplied additional foundation layers for the application. The project was developed using ArcGIS Online and ArcGIS 10.2 Desktop. An ArcGIS 10 server application was developed in JavaScript which can run on most platforms, including mobile devices, to serve up these data based on security roles.

Key findings. The application allows users to identify and query geographic locations of individual or aggregated physicians, to perform drive-time or buffer analyses, and to explore sociodemographic population data by the geographic area of choice. Specific organizations and groups also benefit in the following ways:

- Mississippi State Department of Health officials can examine the aggregate distribution of physicians by county or public health district visualizing health professional shortage areas.
- Medical students and residents can identify areas qualifying for loan repayment programs and investigate suitable practice locations by reviewing population and area demographics and socioeconomic indicators in their areas of interest, thus identifying opportunities in health professional shortage areas early in their careers.
- Rural Physician and Dentist Scholarship Program administrators can track scholars and assess their impact on filling the needs of underserved communities. Recruitment of students from specific areas of need into the scholarship programs can increase the likelihood that they may return to those areas to practice. Conversely, health planners throughout the state can identify rural scholars from their areas for potential recruitment back to their communities.
- The OMPW can analyze patterns and trends of the health workforce over time and across the state, including attrition, saturated areas, and shortage areas.

Implications. This interactive, spatial, web-based application with analytical tools visually represents the physician workforce and its attributes, and provides access to much needed information for state-wide health workforce planning and research. The integrated and visualized data being presented improve awareness of areas in need of physicians which is useful to local and state agencies and the state legislature for making funding decisions and developing health policies. This application is an expandable tool that enables the State of Mississippi to become more proactive in addressing the needs for physicians throughout the state.

Future Directions.

- We continue to add functionality and depth to the application and intend to incorporate more advanced analysis methods, such as linear programming optimization techniques, to examine inequalities in physician availability to population demographics and determine optimal numbers needed.
- We have introduced the tool to a number of key stakeholders, including the governor's office, and have received very positive feedback. We plan to measure use statistics over time and administer satisfaction and usability surveys to user groups.

Funding source. Office of Mississippi Physician Workforce

Exploring the Content and Ranking of Diagnosis-Based Medical Problem Lists

John C. Krauss, MD, and Charles P. Friedman, PhD, University of Michigan, Ann Arbor, MI

Introduction. The diagnosis-based problem list is commonly used by clinicians to summarize the health status of a patient and organize strategies for his/her care . The problem list is a key component of the medical record; reviewing the problem list at each visit is a criterion for Meaningful Use. From an informatics perspective, the optimal strategies for problem list representation and curation are not known. Problems lists have been the focus of some, but not many, empirical studies[1]. This study assessed the generation and organization of the problem list by experienced clinicians for three complex internal medicine cases.

Methods. Eighteen physicians, averaging 19 years post-medical school graduation, reviewed three detailed patient case descriptions that have been used in previous studies of clinical reasoning[2]. For each case, they generated a problem list, transferred the problem list to cards, and then organized the cards into a list. To standardize representation of each problem as much as possible without constraining their choices, subjects generated their problem lists with reference to a provided set of candidate problems. Subjects could omit from their lists problems on the candidate set that they did not believe were important, and they could add other problems that were seen as important. After completing all three cases, the physicians were asked to explain the logic they used to organize their problem lists.

Results. The average numbers of problems included in subjects' lists were 8 (SD = 3), 12 (SD = 4), and 7 (SD = 3) for Cases A, B, and C respectively. Across all subjects, the number of unique problems listed for each of the cases was 24, 35, and 22. For each case there was substantial but far from complete agreement across subjects on the specific problems included. For Case A, the fifth most commonly listed problem was listed by 72% of subjects; for Cases B and C, the comparable percentages were 78% and 61%. The number of unique problems listed displayed more variance by case (variance component = 6.14) than by physician (variance component = 4.47). Thus there was little evidence of a consistent tendency of the subjects to be parsimonious or inclusive in the creating their problem lists. Ordering of problems within lists also was highly variable. The most commonly reported criteria for organizing problems within lists were "acuity" (n =8), "degree of life threat" (n = 4), "dangerousness" (n = 2), and need for "immediate attention" (n = 2).

Conclusions. Problem lists are highly variable and thus highly subjective. When experienced physicians were presented with identical case descriptions, a subset of problems appeared on most physicians' lists; but there was significant variance in how many problems were considered important enough to list, as well as the ordering of the listed items. Our data suggest that there is no one problem list for a patient, but rather different problem lists as generated through the lens of each clinician. This variability poses significant challenges for patient care, particularly for continuity of care in acute settings, as each physician may focus only the problems he/she prioritizes. This variability also raises a challenge for the design of EHRs to capture diverging views of the multiple physicians who care for the patient. While physicians put different labels on how they rank problems, in general the problem list was organized by all physicians based on their own interpretations, expressed in different ways, of seriousness, acuity or threat of mortality.

Exactly What Kind of Patient Data Do They Use in Research? : Analysis of Clinical Data Requests for Research

Rita Kurtz, BA, Elizabeth Bell, MPH, Hyeoneui Kim, RN, PhD
Division of Biomedical Informatics, University of California, San Diego, La Jolla, CA

Abstract
We analyzed data request logs created by the researchers at University of California San Diego (USCD) to better understand what kind of patient data items are actually utilized in biomedical research. The goal of this analysis was to inform the development of the tool that captures patient's data sharing preference. The results revealed that various types of patient data are requested and obtained for research. We need to develop a succinct yet comprehensive patient data category structure, with which patients can easily indicate data sharing preference and are sufficiently informed on their data use.

Introduction
Currently, informed consent is given by a several page long paper form, which is written in technical language and small font, and is often difficult to read and understand by the patient. Patients rarely read through the consent completely, but just sign it to receive the necessary healthcare service. Allowing a tiered manner of informed consent has been proposed as a way to better capture patient's preference on data sharing (1). Literature reported on the typical data items that are considered "sensitive" (2), however they do not take into account the data that is actually requested by researchers, and therefore cannot represent the full spectrum of sensitive patient data nor reflect the most accurate patient preference on data sharing. Therefore, to better understand the scope of the patient data actually used in biomedical research, we analyzed the data request logs collected at UCSD.

Methods
We analyzed 62 data request logs collected from September 2011 to July 2013. The request logs capture the patient data items requested by and provided to the researchers. Each requested item was organized first into "sensitive" categories suggested by the literature, comprising of demographics, diagnosis, lab and test results, medications, and medical procedures. If the requested item did not fall into any of the suggested categories, additional categories were created to encompass them, including PHI data, encounter information, insurance status, body measurements/vital signs, family history, and social history. Frequencies of items in each category were documented.

Results
While the majority of requests did ask for data covered by the sensitive data categories already suggested by the literature, more than half of requests asked for at least one patient data item that a patient might consider sensitive that was not yet covered. Examples of such patient data items are encounter information including provider name and service facility (34%), body measurement such as BMI (29%), insurance status (8%), family history (6%) and social history (6%). We developed an initial ontology for the data categories that patients can browse and indicate their preference for data sharing. The request analysis data and the initial ontology are available at https://idash-data.ucsd.edu/community/51

Conclusions and Future Directions
This study implies the need for a more comprehensive list of patient data categories to present for more accurate capture of patient's data sharing preference.

Learning from Social Media Patient Platforms: A Framework for Exploring Mechanisms Used to Engage Patients

Claudia Lai, MSc[1]; Alex R. Jadad, MD, DPhil[1-3]; Raisa Deber, PhD[1]; Aviv Shachak, PhD[1]
[1]Institute of Health Policy, Management & Evaluation, University of Toronto, Toronto ON; [2]Department of Anesthesia and Dalla Lana School of Public Health, U of Toronto, Toronto, ON; [3]Centre for Global eHealth Innovation, University Health Network, Toronto ON

Abstract

Despite the growing interest in engaging patient in their health care process, particularly with technology, it is not clear how best to do so. Based on a narrative literature review and pilot analysis, we propose a preliminary framework to explore mechanisms used by social media platforms to engage users in health and information sharing processes, which can contribute valuable insights to support the future design of healthcare information systems.

Introduction

Patient engagement is now considered a pillar of the ideal patient centered care model, with a growing view that engaged and empowered patients are essential to improve health and decrease healthcare costs. However, despite the strong political interest in patient engagement, particularly with technology, it is not clear how best to do so. A novel approach to seek ways for better engaging and supporting patients with technology is to explore social media platforms designed for those who wish to become more involved in their health and health care decisions. Social media platforms offer rich applications, services and tools to engage users to learn how to better address their health issues. These platforms can achieve high levels of user participation outside the realm of the health care system. Thus, the objective was to develop a framework for analyzing health related social media platforms for the purpose of exploring mechanisms they use to engage patients in their health care process.

Methods

A review of the literature on patient engagement (in particular patient engagement frameworks) and patient roles in treatment decision-making was conducted to inform a preliminary framework to guide data collection and analysis. Qualitative methods were used to analyze textual and visual data (e.g., platform policies, terms of use, about us, frequently asked questions, registration process, tools, and clients) collected from a convenience sample of social media platforms.

Results

A preliminary framework was developed based on the literature review and pilot analysis. This framework draws from 1) the National eHealth Consortium patient engagement framework that attempts to align to meaningful use policies (inform me, engage me, empower me, partner with me, and support my eCommunity), 2) the Health Council of Canada's spectrum of engagement that encourages patients to participate and influence health care reform policies to improve the effectiveness of the health care system (inform, consult, involve, collaborate, empower), and 3) concepts identified by Deber et al.[1] on preferred patient roles in treatment decisions (passive, shared and, autonomous).

Discussion:

We propose a framework that can be used to analyze social media platforms that engage users who wish to be more involved in decisions relating to their health. We plan to employ this framework in a larger study of purposely selected social media platforms (e.g. sites with many registered users stratified by various characteristics representing different ownership types, funding sources and target users), and further refine it based on the findings. This novel approach to explore mechanisms to engage users in health and information sharing processes can contribute valuable insights to inform future policies and support the future design of health information systems to better engage and support patients within health care organizations.

Challenges Faced When Designing and Conducting Time Motion Studies in Health Care Environments

Barbara A. Lara MD MPH[1], Alexa Meara MD[2], Stacy Ardoin MD[2], Peter Embi MD MS[1], Po-Yin Yen RN PhD[1]
[1]Department of Biomedical Informatics, [2]Department of Internal Medicine, Division of Rheumatology, The Ohio State University Wexner Medical Center

Introduction: Clinical workflow describes a process that comprises a wide range of activities executed by health personnel to provide patient care. Understanding clinical workflow has progressively been recognized as an essential component of successful Health Information Technology implementation and adoption. Originally created as a business efficiency assessment technique, Time Motion Studies (TMS) have been adopted as a working method to describe and assess clinical workflow. While some standards about the methods used to conduct TMS have been provided[1], existing literature only provides general guidelines for designing TMS, but do not address practical challenges encountered when using this method[2]. Here we present a set of common challenges based on our group's experience.

Methods: Based on several TMS conducted by our group over the past years, we outlined crucial steps in the design and implementation process of TMS. Along with these steps we also identified a set of challenges that are distinct unique to the methodology required to conduct continuous observation TMS.

Results: We describe the most interesting challenges encountered by our group despite careful planning. We categorized them based on the phase of the study in which they were encountered. Full description and guidelines of a step by step design and implementation of TMS will be published elsewhere.

#1. **Difficult observation arrangement for sampling purposes:** To study clinical workflow that involves observing clinician-patient interaction, either clinicians or patients need to be enrolled beforehand. However, estimating the amount of observer-time, calendar time and exact calendar schedule can be challenging, as clinicians often change shifts, and patients cancel or no-show to their appointments and none of these events are predictable. Frequently, even when many potential encounters are programmed to happen sparsely on a specific day, they might take place simultaneously, preventing the observers to observe all of them.

#2. **Clinical personnel reluctant to participate:** Groups of clinicians rotate through their units throughout the year (float staff). These personnel are usually not informed of the study and are thus reluctant to participate or collaborate. This hinders data collection for that specific event which in turn compromises the sampling strategy.

#3. **Training observers and maintaining inter-observer reliability is costly and labor intensive:** Data collected for TMS is "observer-dependent", which requires consistent and highly trained personnel, to ensure study validity and reliability. Furthermore, understanding and thus being able to collect data in specific clinical environments requires subject matter expertise and/or intensive training. Moreover, because of ethical and medical issues involved when clinician-patient encounters are part of the observation event, direct training on site might not be feasible. Methods to train observers in a controlled environment are required, increasing the complexity of this process.

#4. **Selecting "reliable" and qualified observers:** Because of the high cost of training, importance of subject matter expertise and data consistency, it is optimal to select "reliable" observers that will commit to work for the full length of the study. Finding observers with the right set of characteristics is a challenge. If a high turnover rate exists, the cost of the TMS increases, prolonging the observation period, and even threatens data consistency.

Conclusion: Previously presented challenges highlight the importance of developing best practice guidelines, where pilot testing might play a significant role in accounting for unexpected variations of the idealized planning design.

Meaningful Use in Medication Reconciliation & Patient Medication Information Management Requires Patient & Healthcare Team Partnership, Community Collaboration, and Standardization: The Veterans Health Administration Story

Maureen Layden, MD, MPH Director Veterans Health Administration Medication Reconciliation Initiative

Medication reconciliation (MedRecon) and medication information management are effective patient interventions to improve care. They have the potential to reduce harm, optimize therapy, improve transitions, and create medication treatment plans that are personalized to patient's preferences and address barriers to adherence. To realize these goals requires collaboration with all stakeholders from the healthcare community, healthcare teams, and leaders in operations, policy making, informatics, quality management, and patient safety. It demands standardization in policies, monitoring, and procedures as well careful evaluation to make certain patients, their caregivers, and healthcare teams can be successful at managing medication information throughout the healthcare continuum. Ultimately, MedRecon needs to be patient centered with foremost consideration of how best to partner with patients, their caregivers, and families.

Challenges: Numerous efforts to improve the exchange of medication information and perform medication reconciliation exist at multiple levels of the Veterans Health Administration (VHA). A concerted effort is needed to establish standards, coordinate platforms, harmonize requirements, and ensure goals are not duplicative to prevent uncoordinated efforts. Lack of an of overarching strategy will increase the risk of failure in meeting external mandates from Centers for Medicare & Medicaid Services Meaningful Use Standards Incentive Programs and Joint Commission Standards as well as internal mandates such as the VHA MedRecon Quality Indicators.

Methods/Strategies: Collaborative interprofessional workgroups comprised of VHA, Department of Defense, and Indian Health Services champions were established to develop business requirements and standards in the following areas: medication information management through the VHA Essential Medication Information Standards Directive, MedRecon policies, patient and staff education programming, effective documentation strategies, performance metrics, and change management campaigns.

Results: The key elements identified deemed necessary for enterprise-wide success in medication information management and MedRecon included: leadership endorsement of a unified enterprise strategy created through community collaboration, founded in standardization and partnership with Veterans, their caregivers, and families.

Conclusion: Partnering with Veterans and their Medications Task Force will execute a colloborative overarching strategy founded in these elements. It will guide iterative development of enterprise programs and tools. Fulfillment of internal and external mandates such as Meaningful Use must be met in the setting where our patients, their caregivers and healthcare teams also experience safe, timely, accurate, understandable, and meaningful distribution of medication information.

Learning Objectives: After reviewing this poster, the learner should be able to:

1. Recognize the importance in engaging and collaborating with key stakeholders so that strategy to meet Meaningful Use MedRecon will also provide value and improvement in the day to day work flow of patient care.
2. Employ strategies that align MedRecon requirements with existing internal and external requirements as the VHA has accomplished with VHA MedRecon Quality Indicators and the Joint Commission Standards.
3. Identify three ways to standardize medication information across the healthcare continuum and manage medication information as part of the medication reconciliation process.
4. Understand the importance in emphasizing patient engagement in any strategy to meet Meaningful Use MedRecon so that it improves their experience and satisfaction with our healthcare organizations.

Considerations in Implementing Informatics Studies in Dementia Care Units

Amanda Lazar[1], Hilaire Thompson, PhD, RN, CNRN, FAAN[1], George Demiris, PhD, FACMI[1]
[1]University of Washington, Seattle, WA

Abstract
Thirty to 40% of people with dementia live in nursing or assisted living facilities and dementia care units, compared to only 2% of older adults without dementia (1). People with dementia living in memory care units are in need of interventions encouraging stimulating activities and meaningful interactions with others. Information and communication technologies (ICT) have the potential to provide opportunities for engagement for this population. We present lessons learned from conducting an evaluation study of a multifunctional technology tool designed to facilitate opportunities for entertainment, cognitive training, communication, and information access with this challenging population. The evaluation approach included both a formative and a summative evaluation of this technology and our study highlights technical and ethical implications for system designers and informatics researchers in the area of dementia care.

Introduction
As the population ages, the number of people with dementia will increase proportionally. The healthcare system is unequipped to deal with the cost of care for dementia, and needs for social interactions and meaningful engagement are often unmet for this population, especially for people living in assisted living and memory care units (2-4). Information and communication technology can provide avenues for people with dementia to interact with others, improve cognitive skills, take part in physical activity, and have fun. In light of this potential, it is imperative to design and evaluate technology tools to improve the wellness and quality of life of this population.

Methods
In a six-month longitudinal study, we used a mixed methods approach to evaluate a commercially available multi-functional technology tool designed to be used by or with older adults with dementia. The tool contained applications for communication, cognitive training, information access, exercise, and leisure activities. The technology tool was used in weekly hour-long sessions with residents and researchers as well as daily at the discretion of staff members. The authors gathered quantitative and qualitative data from the three stakeholder groups in a person with dementia's care: the individual with dementia, a close family member, and staff in the memory care unit. Data sources included interviews, standardized instruments, and system logs.

Results
Lessons learned from conducting a technology evaluation in a memory care unit involve technical and ethical aspects as well as human computer interaction challenges. Conducting a study in a memory care unit and working with a population with dementia can be challenging. An important facilitator is the approach of introducing the intervention to family members and staff to ensure greater buy-in. This was because people with dementia were not able to use the system independently and thus the system had to be integrated into unit programming and care. A common issue to overcome was the perception of family members who thought their relatives would be unable to use or benefit from the technology due to the severity of their dementia, although this was not the case. We also include considerations for planning study sessions and the administration of standardized instruments with people with dementia in a memory care unit, including how to determine the best time to conduct study procedures. These findings will help researchers plan studies working with this population in the future.

Abstract

Patients in transition of care suffer from adverse events, which results in readmission or morbidities. Patient's active engagement in the discharge process is one promising solution. A web-based patient-centered discharge checklist toolkit and summarized discharge instruction frame were developed. The development process and the result were described.

Introduction

Many discharged patients suffer from adverse events, which results in readmission or morbidities[1]. Active engagement of patients in the discharge process is one promising solution. Several kinds of discharge checklists for patients and providers have been developed for this purpose. Patients can understand the discharge plan and instructions more effectively if a patient-centered discharge checklist is provided electronically and interactively. We developed a web-based patient-centered discharge checklist toolkit (PCDCT) and described the development process and the result.

Methods

Development of our PCDCT was conducted as a subproject of a web-based patient-centered toolkit (PCTK), which was designed for hospitalized patients to participate actively in their hospital stay and treatment by using tablet devices. Our team was composed of multidisciplinary informatics researchers and hospital staff members. A modified version of the Robert Wood Johnson Foundation discharge preparation checklist was used that categorized discharge checklist items and a medication checklist. A prototype of PCDCT was developed after category names and the order of checklist items were modified. Each checklist category was displayed completely in a window without a scroll bar. The prototype was changed iteratively after meetings with care providers and a patient advocate. To give reliable information to patients completing the PCDCT, a discharge instruction frame was also developed.

Result

PCDCT and discharge instruction frame were developed and implemented into the PCTK. PCDCT was composed of five steps: 1) an introduction to the discharge checklist, 2) 'My follow-up plan', 3) 'My medications', 4) 'My self-care management', and 5) 'My discharge plan of care'. A message tool for real-time communication with the care team was also implemented. Thus, patients could ask questions if they wanted more information about the discharge plan. The discharge instruction was also provided to get detailed information without the help of the care team. Contents were retrieved from the discharge module by using an existing web service. Once patients complete the discharge checklist, a message of 'Now you can leave the hospital safely' was designed to display.

Conclusion

Our next steps are completion of the interface with the existing discharge module and development of an electronic form of the discharge instructions. We expect that this toolkit can help patient engage in discharge process actively.

A Case Study on Integrating a Genealogy Database into a Consumer-Facing Family Health History Tool

Jaehoon Lee, PhD[1], Nathan C. Hulse, PhD[1,2], David P. Taylor, PhD[2], Pallavi Ranade-Kharkar,MS[1,2]
Grant M. Wood[2], Peter J. Haug, MD[1,2], Stanley M. Huff, MD[1,2]
[1]University of Utah, Salt Lake City, UT; [2]Intermountain Healthcare, Murray, UT

Abstract

In this study we integrated family history data from the FamilySearch.org genealogy database with a consumer-facing, family health history (FHH) tool: OurFamilyHealth. A data import plug-in was developed to 1) retrieve family history data from FamilySearch.org, and 2) convert them into an internal FHH data model for clinical use in OurFamilyHealth. We successfully translated between the two models and demonstrated the feasibility of system integration. We anticipate that adding this feature will make it easier for our patients to enter rich FHH data.

Background

OurFamilyHealth is a locally-developed FHH tool used at Intermountain Healthcare[1]. Currently it provides two methods for patients to enter family members, manually or through uploading a GEDCOM (GEnealogical Data COMmunication) formatted genealogy file. FamilySearch.org is a worldwide genealogy database that provides an application programming interface (API) allowing external applications to access its family history data via the web[2]. Through OurFamilyHealth's use of this API, a patient who has already entered family history in FamilySearch can provide authorization to directly import his/her data into OurFamilyHealth as a starting point for entering FHH.

Method

The family history data in FamilySearch.org includes demographics, family relationships, events (e.g. birth, death, burial, marriage, divorce, etc.), among others. Certain relevant elements conceptually match to those of the FHH data model in OurFamilyHealth and could be consumed by the application. We utilized the Family Search APIs to retrieve data through web services, and translated between the two data models using transformations (See Table 1).

Table 1. Transformation of family history data from FamilySearch.org to OurFamilyHealth

Category	Transformation
Demographics	Name, gender, birth date, death date are transferred directly.
Uncertainty of date	If a birth date or death date has an attribute of about / after / before, it is considered as an approximate date.
Living status	If a person has a death date, he/she is considered deceased.
Adopted status	If a parent-children relationship has attribute of adopted / foster / guardianship, the child is considered adopted.
Family relationship	OurFamilyHealth consumes 3 degrees of family relationships which are meaningful for genetic risk assessment; 1st: parents, children, siblings, 2nd: grandparents, grandchildren, half-siblings, uncles / aunts, nieces / nephews, 3rd: great grandparents, great grandchildren, 1st cousins, half nieces / nephews, grandnieces / grandnephews, great uncles / aunts.
Marital status	Nine types of spouse relationships are mapped to four marital statuses. Multiple spouses and their dependent families are also transformed.

Conclusion and future work

Prototyping in an Intermountain Healthcare development environment using the FamilySearch.org sandbox database demonstrated that the proposed approach is reasonable in terms of data transformation and system integration. Our future work is to: 1) certify the application with FamilySearch.org so that we can eventually integrate with their production database, and 2) implement the application in the Intermountain production environment.

The Development of a Mobile Nurse Shift Reporting Application based on Human-Computer Interaction Design

Mikyoung Lee, PhD, RN[1], Anna McDaniel, PhD, RN[2], Josette Jones, PhD, RN,[3] Denise Kerley, BSN, RN[4]

[1]Assistant Professor, Indiana Univ. School of Nursing, Indianapolis, IN, [2]Dean & Professor, Univ. of Florida College of Nursing, Gainesville, FL, [3]PhD, RN, Associate Professor, Indiana Univ. School of Informatics & Computing, Indianapolis, IN, [4]BSN, RN, Indiana Univ. Health University Hospital, Indianapolis, IN

Abstract

The use of mobile technologies for health care delivery is increasingly advocated. Yet little research exists about its use for nursing handoff communication. This study aimed at developing a mobile nurse shift reporting application, based on the principles of human-computer interaction design, using a focus group of practicing nurses. The new mobile application will lead nurses to capture/handover patient information in a systematic and standardized manner, and support safe, efficient, patient-centered bedside handoffs.

Introduction

Dynamic and complex clinical environments present many challenges for effective communication among health care providers. Nurse shift report (NSR) is an important communication process that plays a pivotal role in the continuity, quality, and safety of patient care. Mobile technologies are increasingly adopted into health care. Yet, little research is available about the mobile application for NSR.

Purpose

The study aimed at identifying users' needs and designing a user-friendly interface of a mobile NSR application integrating the American Association for Critical Care Nurses (AACN) Synergy model[1]

Method

With the focus group, consisting of 12 staff nurses from 6 different care units at an academic medical center, we composed and organized 175 candidate data elements, based on the analysis of current shift reporting practice, on a low fidelity prototype mobile application. The common critical and unit specific care elements necessary for NSR across the units were identified and coincided with 8 patient characteristics defined by the Synergy model. Based on human-computer interaction (HCI) design principles,[2] we asked semi-structured questions to elicit nurses' feedback on the critical interface features for shift-report repeatedly along with the demonstrations of the revised designs.

Results

Regarding interface features, there were initially different preferences by nurses from different units, but not by nurses' years of clinical experiences. Considering the nurses' preferences, HCI design principles, and usability principles,[3] the mobile NSR application was developed. Most nurses preferred one page fill-in form; however, they also wanted a navigating system. The care elements coincided with 8 patient characteristics were placed in the tab order of Vulnerability, Stability, Resiliency, Predictability, Resource Availability, Participation in Decision Making, Participation in Care, and Complexity. This order was made by the nurses' perceptions on the priority of those care components critical for capturing and reporting the patient's conditions at shift change. A rating system of each patient characteristic based on the patient condition was also created to assist nurses to judge the severity of patient conditions in total scores of patient characteristics. The terms and abbreviations were consistent with the ones of electronic health record that nurses were using. As different units deal with different amount of information on patient conditions, the data elements are set to be shown or hidden interactively according to unit characteristics. Key concerns are highlighted in red color to get more attention from nurses.

Conclusions

The focus group nurses anticipated that this new mobile NSR application would be a more focused tool for nurses to capture critical patient information, and would lead to improvements in nurse-to-nurse communication and coordination. Its usability testing will be conducted with additional staff nurses of the units in the hospital.

Patient Safety Education using an Electronic Error Reporting System

Nam-Ju Lee, RN, PhD[1]
[1] College of Nursing, Seoul National University, Korea

Abstract

The purpose of this study was to develop an electronic error reporting system and implement it into a nursing curriculum in an effort to improve students' competencies related to error reporting. The electronic error reporting system was developed and the WHO-International Classification (WHO-ICPS) for Patient Safety was used. 76 nursing students reported 236 errors during a five-week clinical practicum. Students' knowledge, attitude and skill competencies related to error reporting all showed significant increases.

Introduction

Error reporting is an essential component in improving patient safety, but many health care providers may be reluctant to report errors due to multiple barriers. Education about error reporting as part of an undergraduate curriculum may reduce resistance to error reporting. The present study was performed as part of a project entitled the 'Development and Evaluation of a Patient Safety Curriculum for the Improvement of Nursing Students' Patient Safety Competencies'. The purpose of the study was to develop an electronic error reporting system and implement it into a nursing curriculum in order to improve students' competencies related to error reporting.

Methods

The error reporting system was designed based on an analysis of the error reporting systems used in teaching hospitals in which nursing students are trained for their clinical practicum. The electronic error reporting form was developed using Google Docs. The form consists of five parts: information about the students, the subject who was harmed or was nearly harmed, error detectors, relevant persons, and relevant events. In the event session, users select the types of events and record a detailed description of an event, its causes, the level of harm, and suggestions to prevent the reoccurrence of the event. The WHO-ICPS was used for standardized terms in the system. After pilot testing with four users, including nurses and nursing students, the form was finalized based on an iterative evaluation process. The study was approved by the institutional review board of the college of nursing and de-identified data were collected. During the clinical orientation, the students learned about general patient safety concepts and were taught how to use the error reporting system. They could access it with a wired or wireless network and document any error that they made or observed during their five-week clinical practicum. It was a voluntary, anonymous process. After the patient safety education sessions, students' error reporting competencies were measured using the questionnaires developed by the research team. The errors were analyzed by type according to the WHO-ICPS and descriptive statistics were used. Content analysis was used to analyze the data collected using focus groups.

Results

236 errors were reported by 76 students. On average, students reported about 3 errors. In 212 events, the patient was the subject who was harmed or nearly harmed. Employees and caregivers accounted for 4.2% each. 79 events were near misses, and 89 occurred without harm. 24 resulted in harm to patients. Students were involved in only 9 events. The most frequent type of error was Medication/IV Fluids (24.6%) followed by Clinical processes/procedures (21.8%), Behavior (12.9%), Clinical administration (6.2%), Patient accidents (5.5%) and Medical device/Equipment errors (5.2%). Students' knowledge, attitude and skill competencies related to error reporting were significantly increased after the implementation of the patient safety curriculum, including the use of the error reporting system. Students reported that they had an opportunity to understand errors systematically. Also, they mentioned that they realized the important role of the error reporting system in improving patient safety. Regarding suggested improvements to the error reporting system, the students noted some ambiguity in the terms used for the error types, the lack of a preview option for subtypes of errors, and limitations related to the user interface (e.g., no back buttons).

Conclusion

Patient safety education using this error reporting system may improve students' understanding of the nature and causes of errors and may therefore help students to identify errors and prevent them during their clinical practicum.

This study was supported by National Research Foundation of Korea (810-20110011, 810-20120011).

The Readability of Diabetes Patient Education Materials on the World Wide Web based on LSA and SVM technique

Ying-Li Lee, RN, MS[1, 2], Hou-Chiang Tseng[3], Yao-Ting Sung, PhD, Professor [4], Ju-Ling Chen, PhD, Assistant Professor [5], Shao-Hui Shu, RN, MSN[6]

[1]Department of Nursing, Chi Mei Medical Center, Tainan, Taiwan; [2]Institute of Biomedical Informatics, National Yang Ming University, Taipei, Taiwan; [3]Research Center for Psychological and Educational Testing, National Taiwan Normal University, Taipei, Taiwan; [4]Department of Educational Psychology and Counseling, National Taiwan Normal University, Taipei, Taiwan; [5] Center for Teacher Education, National Taitung University, Taitung, Taiwan ; [6]Faculty of Nursing, Tzu Chi College of Technology, Haulian, Taiwan

Abstract

We used latent semantic analysis (LSA) and support vector machine (SVM) to analyze the readability of education materials from the websites for diabetes patients in Taiwan. Our purposes are to evaluate the readability of these texts and to give suggestion to health professional educators.

Introduction

Readability refers the degree to which a text can be understood. The readability of patient education materials on the websites may affect the effectiveness of patient education. Traditional readability measures are primarily based on the number of words in the sentences and the number of letters or syllables per word. However, domain-specific texts contain many professional terms that should not be predicted using traditional readability formula only. LSA have been commonly used to classify texts containing domain-specific knowledge. This study aims to evaluate the readability of diabetes patient education materials by LSA and SVM technique.

Method

The readability model bases on LSA (Tseng, Chang, Chen & Sung, 2014) were used to analyze the readability of texts. Through latent semantic space, any word, text or set of texts can be transformed into a semantic vector for representing the association within domain knowledge. In the modeling stage, we applied 6230 texts from textbooks of Chinese language arts, natural science, social science, physical and health educations to develop the corpus. The Chinese Readability Index Explorer 2.0 (CRIE2.0) was used for word segmentation and tagging. The word list contained important words of each grade (G1-12) per subject was developed by LSA and was used to calculate readability indicator of each text in our study. Then, we used SVM to develop the readability model for evaluating domain-specific patient education materials. In the testing stage, we input 249 texts of diabetes patient education to the readability model and to evaluate the grade level of each text.

Result

249 patient education materials from websites were selected from 15 medical centers in Taiwan. The average coverage rate of conceptual knowledge to our corpus was .77 ± .078. Only 37.65% (n=93) of texts were the revised editions in 3 years. 29.72% (n=74) of texts did not show the published year. None of the texts marked the grade level of text. 88.4% (n=220) of diabetes patient education texts were non-specific type of diabetes. The results showed that the text with the highest readability indicator was senior high school level (G10-12) and the easiest was G1. We found that the readability indicator of 22.09% (n=55) texts graded to junior high school level (G7-9) and 34.54% (n=83) graded to senior high school level.

Conclusion

34.54% of the diabetes patients education materials on websites in Taiwan were too difficult to read for patients with an elementary school or junior high school education degree. Hence, the results of this study showed that we may underestimate the difficulty of these texts. The results supported that medical terminologies and health professional concepts should take into account as well as domain-specific knowledge when evaluate texts in patient education materials. In the future, we will integrate medical terminology and health professional concept into the readability model to improve the validity of the analysis.

The Association between Numeracy Component of Health Literacy and Online Health Information Seeking Behavior

Young Ji Lee, PhD, RN
Department of Preventive Medicine, Northwestern University, Chicago, IL

Abstract
Numeracy is an important component of health literacy; however, its importance has been understudied among online health information seekers. The aim of the study is to explore the association between the numeracy component of health literacy and online health information-seeking behaviors (HISBs) using the Health Information National Trends Survey 2007 dataset. This study found that the numeracy component of health literacy is positively associated with online health information-seeking behaviors.

Introduction
Health literacy has been a challenge for people who seek health information from the Internet. One of the Healthy People 2020 objectives is "to increase the number of online health information seekers who report easily accessing health information". To accomplish this goal, improvement in health literacy is an obvious step. However, previous studies have focused only on the association between reading skills and online health information-seeking behaviors, although numeracy is a key component of health literacy.[1-3] Therefore, the association between numeracy and online health information-seeking behaviors (HISBs) must be identified and emphasized.

Methods
This study used HINTS 2007 data since this dataset is the only set that includes health literacy-related variables among the HINTS data sets. Statistical Package for the Social Sciences (SPSS) Version 20.0 software was used to analyze the data. First, the chi-squared test was used to examine differences in categorical variables according to online HISBs. Then, multilevel logistic regression was conducted to examine the association between the numeracy component of health literacy and online HISBs.

Results
Among the entire sample, 4,820 participants answered the online HISB-related questionnaire; 42.6% of respondents had sought health-related information from the Internet. Significant variables in the bivariate analyses were age, education level, race/ethnicity, employment status, cancer history, and numeracy. Based on the multilevel logistic regression, individuals who depend on numbers to make health decisions are likely to seek online health information. Additionally, participants who are younger, have higher education, and are employed are likely to turn to the Internet for health information. The final model was significant and demonstrated a good fit with the data.

Table 1. Multilevel logistic regression explaining respondents' online HISBs (*b*=coefficient; $^{*}p<.05$ $^{**}p<.01$ $^{***}p<.001$)

Explanatory variables		**Model *b***
Demographic & Health situation factors	Age	-0.538***
	Education level	0.633*
	Employment	0.181**
	Cancer History	0.016
Health literacy	Med stats	-0.054
	Numbers are helpful	-0.131***

Conclusion
This study showed that numeracy component of health literacy is positively associated with online HISBs. Further study with the recent data is needed to explore the trends of the association.

Interstate Exchange Implications for Multiple Health Information Networks

Cynthia LeRouge, Ph.D.[1], Jennifer Tillman, M.H.A.[1], Joanna Hirsch, J.D.[1]
[1] Saint Louis University, St. Louis, Missouri

Abstract
The case for health information exchange networks within states is gaining increasing growth and acceptance. Use cases also exist for interstate exchange (ISE). This study explores the latest ISE value propositions, use case scenarios, and barriers that can be found in literature review and interviews with healthcare organizations.

Introduction
Exchanging patient information through ISE among multiple state health information networks (HINs) improves communication and advances the coordination of care among a larger network of providers. In particular, ISE could prove beneficial for providers practicing in multiple states. In addition, patients could benefit, specifically those who live and receive primary care in rural and smaller communities, but cross state lines to receive specialty care in metropolitan areas. The value propositions of state-level HINs have been realized; however, there is a need for further understanding of the many benefits of ISE. Although there is a federal vision for a nationwide, public-private partnership, this national HIN is not functioning at this time and little is known about this endeavor.

Methods
Data was gathered through a literature review of ISE articles from 2009 and 2013 based on a search of common health informatics databases using the following terms: Interstate Exchange, Health Information Network, Direct, e-Health, Health IT, Western State Consortium, and Gulf Coast Task Force (contact authors for a list of literature). In addition, seven, 60-minute structured telephone interviews were conducted with leaders of state and regional HINs from five states in varying stages of implementation of intrastate and ISE to explore value propositions, use cases, and suggestions for meeting challenges. Thematic coding was completed using Dedoose © qualitative software.

Results
The value propositions related to ISE create compelling cases that center around rural patients crossing state lines to seek specialized medical care in urban centers, health systems and individual providers having a presence in multiple states, service to migrant communities, and the facilitation of care resulting from natural disasters. Direct seems to be the easiest method of exchange; however, Query-based Exchange could have a more extensive impact. Results to date (see Figure 1) indicate barriers and potential suggestions for addressing challenges to ISE.

Barrier	Possible Means to Address
Concerns relating to the need to obtain a clear understanding of other state's privacy laws	Reconcile state laws relating to purpose of use, participant eligibility identification, and content of transactions
Lack of similar patient consent policies among all states	Include patient consent status and segment sensitive data
Concerns of potential liability for improper disclosure of patient information, including in disaster situations	Address disaster policies within ISE agreements, including clearly defined scenarios for "Break the Glass" policies
Concerns that participation could lead to a loss of control over their patients' health information	Establishment of clearly defined purpose of use, auditing, and penalty policies
Concerns related to the costs to update HIN platforms, implement, and participate in ISE	Clearly delineated allocation of costs among all state HINs
Distrust towards inclusion of non-provider participants	Development of a participant authorization process
Concerns related to managing multiple agreements with differing terms	Use of one participation agreement and development of a governing model to oversee data exchange
Perception that some states will wait to join national HIN	Heighten awareness on realistic timing for a national HIN
Administrative burden to notify patients that data is on ISE	

Discussion
Though barriers exist, exchanging patient information through ISE has the potential to demonstrate improved coordination of care to provide greater convenience and better health outcomes for patients. State HIN's interviewed seem to be well aware of the benefits and barriers and are proactively seeking the means to address these challenges.

Using Natural Language Processing for Autism Trigger Extraction

Gondy Leroy, PhD, Margaret Kurzius-Spencer, PhD, Sydney Pettygrove, PhD

University of Arizona, Tucson, AZ

Abstract

The Arizona Developmental Disabilities Surveillance Program collects and abstracts special education and clinical records on 8-year old children with behaviors suggestive of autism. Natural language processing (NLP) tools are developed as part of a feasibility study of information extraction. The NLP algorithms combine standard components with customized gazetteers and finite state automata. The algorithms were evaluated on 36 records from which 19 triggers were extracted with 68% precision.

Introduction

Autism Spectrum Disorder affects about 1 in 88 children in the U.S. and its prevalence increased more than two-fold since 2000. Whether this increase is due to a true increase or better knowledge and reporting of characteristics by educators and clinicians is debated. The Arizona Developmental Disabilities Surveillance Program is part of the CDC Autism and Developmental Disability Monitoring Network and has been tracking children biennially in Maricopa County (AZ) since 2000. Using ARCHE database software, special education and clinician records of children who turned 8-years old and showed signs or symptoms of autism (i.e., 'triggers') are abstracted for further evaluation. We are developing NLP tools to extract information automatically and report on a feasibility study.

Text Mining of Abstractions

All records were processed using GATE[1]'s tokenizer, sentence splitter, and Parts-of-Speech tagger. Custom gazetteers were created to recognize trigger words. Only words that appear in the ARCHE Abstraction Manual were included (Table 1). Eighteen Java Annotation Pattern Engine (JAPE) rules were developed to annotate diverse combinations of trigger words as 'triggers'. JAPEs are implemented as finite state automata (FSA) in GATE.

Thirty-six abstracted, de-identified records were selected at random from two school districts in Arizona (Table 2). In these, a total of 19 triggers (5, 5 and 9 in resp. 2000, 2006, and 2010), e.g., "lack of social or emotional reciprocity", were extracted from the text with 68% precision. Errors were generally due to too general extractions, e.g., "not play imaginative games" is not sufficiently specific to ASD.

Table 1. Words in Customized Gazetteers

Gazetteer & JAPE	**N**
Social Connectedness / Nonsocial Connectedness	33 / 21
Social Object / Nonsocial Object	41 / 17
Social Gesture / Nonsocial Gesture	85 / 27
Inappropriate (manner)	18
Excessive (manner)	26
Absent (manner)	65
JAPE rules	18

Table 2. Text characteristics.

	Study Year			
Avg. Per Record	**2000 (N=12)**	**2006 (N=12)**	**2010 (N=12)**	**All (N=36)**
Words	589	396	481	**488**
Sentences	32	23	26	**27**
Trigger Words	39	28	32	**33**
Triggers	.42	.42	.75	**.53**
Precision	80	80	56	**68**

Conclusion and Future Work

The approach shows feasibility of extracting triggers automatically from text. Future work will include gazetteer expansion using the UMLS and developing additional JAPE rules to increase recall of triggers. Support vector machine (SVM) classification will be used to increase precision. Once sensitivity and specificity have reached acceptable levels, more records will be processed to compare study years and for further text mining.

Title: Automating Identification of Multiple Chronic Conditions in Clinical Practice Guidelines

Authors and Affiliations: Tiffany I Leung, MD, MPH[1,2], Hawre Jalal, MD, PhD, MSc[1,2], Donna M Zulman, MD, MS[1,3], Douglas K Owens, MD, MSc[1,2], Mark A Musen, MD, PhD[4], Michel Dumontier, PhD[4], Mary K Goldstein, MD, MS[1,2]

Introduction: Two-thirds of Medicare beneficiaries have multiple chronic conditions (MCCs), or two or more chronic conditions, but clinical practice guidelines (CPGs) generally focus on single conditions. Providing guidance on managing patients with MCCs is critical for practicing clinicians. However, it is unclear to what degree disease-specific CPGs provide guidance about comorbid conditions. We developed and evaluated an automated method to determine the extent to which disease-specific CPG recommendations mention comorbid conditions.

Methods: This study focuses on guidelines for the 15 most prevalent Medicare chronic disease diagnoses, excluding *cancer* given the breadth of the term, and adding *obesity* due to its high prevalence and clinical significance. We compiled a corpus of text from CPG summaries available in the National Guideline Clearinghouse (NGC). CPG summaries are extracted from full text clinical practice guidelines published by guideline-authoring committees and organizations. CPG summaries were included if (1) at least one of the 15 diseases was mentioned in the title and (2) the target population was the general adult, non-pregnant population. To identify the set of CPG summaries for analysis, we searched their titles for the 15 chronic diseases of interest using both text search and manual verification of the titles against inclusion criteria. To complete the text corpus, we then combined CPG summaries that had been extracted from the same full guideline.

To develop our algorithm, first, we retrieved a list of relevant ICD-9 codes from the Medicare Chronic Disease Warehouse for 14 of the 15 chronic diseases, and utilized three ICD-9 codes for *obesity*. Then, we queried the Bioportal ontologies in the National Center for Biomedical Ontology for synonyms mapped to the set of ICD-9 codes. Next, we developed a text matching algorithm to search for the comorbid disease synonyms in the CPGs' Recommendation sections. Finally, we tabulated the proportion of CPGs mentioning comorbid disease terms, and the number of comorbid disease terms mentioned in each CPG. To evaluate the automated approach, 30 CPGs (two for each chronic disease) were selected using stratified random sampling, and two annotators with medical expertise performed sentence-level manual annotation to generate a reference standard.

Results: We obtained 2,503 unique CPG summaries from the NGC; 314 met inclusion criteria, and after processing to build the text corpus, 273 were available for analysis. Guidelines for concordant diseases (diseases that are part of the same pathophysiologic risk profile), such as hypertension, diabetes, and hyperlipidemia, mentioned one another most frequently. Hypertension was the only disease mentioned across all CPGs, while Alzheimer's disease and osteoporosis were mentioned the least. Annotators agreed on 96.95% of the 2,891 sentences in the pilot reference standard.

Conclusions: We developed an automated method that identifies comorbid disease terms in CPG recommendations. Evaluation of the method against the reference standard is in progress. Also, an annotation guide to improve the reference standard is in development. This method may be useful to describe important comorbidity relationships, inform gaps in guideline recommendations regarding comorbid diseases and therefore identify opportunities for guideline improvement. Further investigation is needed to understand the context and variation of comorbid disease mentions in CPGs.

The Challenges of Disparate Data Formats: Analysis and Visualization in the SLIDES Project

Ang Li[1], Steven Chall, MS[2], Allison Vorderstrasse, DNSc[1], Constance M. Johnson, PhD[1]

[1]Duke University, Durham, NC; [2]Renaissance Computing Institute, Chapel Hill, NC

Abstract

Type 2 Diabetes (T2D) is a chronic disease epidemic in the U.S. Innovative interventions that empower patients in diabetes self-management (DSM) are needed to decrease morbidity and mortality associated with this disease. We developed and tested a virtual environment (VE) for adults with T2D and collected multidimensional data over a period of 6 months. We employed visualization techniques to reveal thematic patterns among our data.

Introduction

Visualization of multidimensional data provides multiple views of the data beyond the traditional 2D perspective. The use of color, shapes, volume, and animation for example allows a greater exploration of the data through visual images. These dynamic drawings can uncover evolutionary paths of change over time. Using animation allowed us to combine multiple types of data and to highlight aspects of our temporal data. As the interactive web becomes a popular mode of delivery of health information, we need interactive research tools to better understand the outcomes of these studies.

Methods

Using data from the SLIDES (*eHealth: Second Life Impacts Diabetes Education & Self-Management)* study, we developed an Internet visualization tool that allowed dynamic data processing with an easy-to-use and implement user interface to evaluate the preliminary effects of VE participation on metabolic outcomes. The kinds of data generated included: text transcribed from audio recordings of participant conversations; numerical avatar positions within the VE; biometric measurements; survey results; images and video. Initially, visualizations were created using the capabilities available in the R environment, an open-source data analysis and statistical computing software. These capabilities were extended by incorporating R-Shiny libraries, which include a larger repertoire of visualization approaches plus web deployment. We next applied the D3.js JavaScript libraries, which allowed us to animate our results and added more versatility and power.

Results

There were a total of 20 participants in this pilot study with T2D. This visualization (Figure 1) allowed us to see through animation how the participants weight, HbA1c (indicator of metabolic control) and corresponding VE activity level changed over the course of the study (6 months). Figure 1 shows screen shots from a browser-based visualization at baseline, 3 and 6 months with color indicating individual participants. The horizontal axis is weight and the vertical axis is HbA1c. The size of each circle is determined by the corresponding subject's activity level.

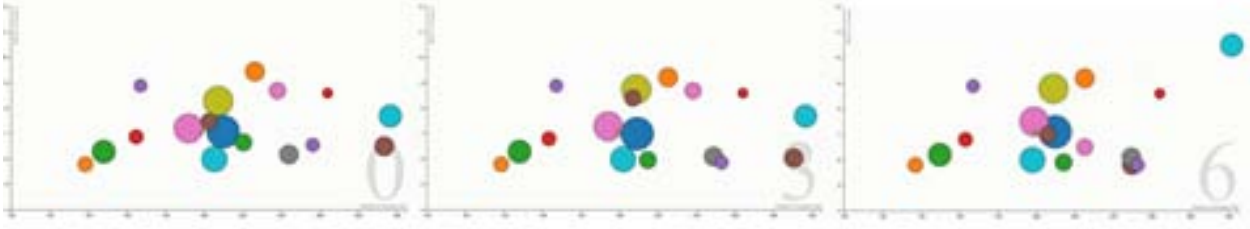

Figure 1. Visualization of participant weight, HbA1c and activity level.

Conclusion

Spatially transforming these different types of related data revealed trends and phenomenon that were not possible to see with traditional graphs. Visually representing these data with animation not only made salient information more apparent, but also allowed us to enhance our understanding of how self-management of T2D can be impacted by time and group dynamics. Major challenges remain in integrating the variety of data gathered in the SLIDES study including problems with rendering raw audio data into a format suitable for analysis, extracting meaning from the resultant text, and especially performance. Finding solutions to these problems could be beneficial to researchers using mixed methods approaches to evaluate healthcare big data. These visualizations help to show how data clusters and in turn helps researchers to see new dimensions to these data.

Reducing the Screening Burden of Systematic Review with a Multiple-level Relevance Ranking System

Dingcheng Li, PhD[1], Zhen Wang, PhD[2], Feichen Shen[1], Mohammad Hassan Murad, MD[1], Hongfang Liu, PhD[1]
Mayo Clinic, Rochester, MN[1], University of Missouri, Kansas City, Missouri[2]

Abstract. *Systematic review (SR) requires time-consuming manual work in screening potentially relevant articles retrieved from multiple databases. In this paper, we propose a multiple-level SR supporting framework including three components: i) the use of relevance ranking to assist the screening process aiming to increase the efficiency without compromising the validity, ii) topic analyses for distributed semantics discovery, and iii) network analyses on relation extracted for comprehensive semantic summarization. The sensitivities on a case study reached above 80% while the screening burdens were lowered to 25% even based on a crude relevance ranking approach. Topic analyses based on Latent Dirichlet Allocations (LDAs) showed the high consistency among the domain experts' selection of articles and relation network analyses displayed clearly the important predicate relations between medical concepts.*

Background and Introduction.

There is an increasing recognition that healthcare providers, researchers, and government agencies should use the body of research evidence to inform their decision making, from the care of individual patients to country-level decisions [1, 2]. As the cornerstone of evidence-based medicine, systematic review (SR) identifies, appraises, and syntheses all literatures regarding to a question of interest in a transparent and systematic way. However, high-quality SRs follow strict procedures (Figure 1) and require significant resources and time. Allen et al estimated that a SR with 1000 potential studies retrieved for abstract screening was predicted to take 952 working hours to complete. A recent evaluation of 63 SRs with 114 reviewers found on average a reviewer spent 0.9 minutes, 7 minutes and 53 minutes on abstract screening, full text screening and data extraction. Thus, methods to increase efficiency of conducting SRs without compromising validity are essential and strongly required.

Methods.

Inspired by our prior work on automated reference assignment [3] , which explores methods for assigning reference automatically to expert-written content, we propose the use of diverse relevance ranking metrics for accelerating the screening process of SR. In addition, we include deep semantic analyses into the SR framework. The first component functions as the screen process in traditional SR, composed of five relevance-ranking metrics: Semantic Relevance Ranking, Journal Relevance Ranking, Citation Relevance Ranking, Publication Type Relevance Ranking and Mesh Concepts Relevance Ranking, plus the Protocol Screening, which form a pipeline workflow. The second component is topic analyses based on Latent Dirichlet Allocations (LDAs) [4] and the third component is the extraction of predicate relations from the semantic MEDLINE.

Results and Discussion.

We piloted this framework in one SR studies conducted by our group. The SR evaluated the effects of pharmacological interventions to prevent or delay the onset of type 2 diabetes. After the manual screening, 38 articles were selected. For DM Prevention shown in Table 1, the total number of articles is 700, the total screening burden, which can still keep 100% of sensitivity using 350 articles and the screening saved is 50%. After we further decreased the screening burden, the sensitivity started to decrease. But even after we reduced the screening burden to 200, the sensitivity reached more than 80% for each case. We found no significant difference on combined effect sizes between different screening burdens and manual screening. However, we noticed the accelerated decreasing speed of screening sensitivity when lowering the screening burden from 200 to 100, which requires further investigation. In addition, the topic analyses demonstrate that the documents after screening focus on a small of topics and majority of the topics are irrelevant to the target SR. Such analyses suggest an alternative way of performing SR screening where we can perform topic analyses first and then screen based on topics. Finally, we performed the network analyses on the final list of articles for SR, which shows clearly the TREAT and PREVENT relations and gives us comprehensive information. All of those results demonstrated that our information retrieval system based on diverse relevance ranking can reduce the labor of SRs to a large degree while keeping comparably high recall.

Table 1. Performance in retrieving relevant articles for DM Prevention

Ranking threshold	False negatives	Sensitivity	Screening saved in percentages	Combined effect size (RR) and 95% confidence interval	Difference between Diverse Relevance Ranking and manual screening (p value)
700	0	100%	0	0.92 (0.86, 0.99)	1.00
350	0	100%	50%	0.92 (0.86, 0.99)	1.00
200	7	82%	71.5%	0.94 (0.88, 1.02)	0.68
100	14	61%	85.7%	0.96 (0.87, 1.05)	0.53

Mayo Clinic, Rochester, MN

Abstract: To facilitate and improve the safety, accuracy, and efficiency of heparin management we designed and developed the Heparin Nomogram System (HNS) – a web based computer application which provides the capability to calculate IV heparin doses, electronically order activated partial thromboplastin time (aPTT) tests and generate reminders through the use of built-in safety check logic. HNS has been used for nearly 50,000 episodes of heparin therapy at Mayo Clinic Hospital Rochester Campus.

Introduction: Heparin has been widely used in a variety of settings to prevent and treat thromboembolic events for over half a century and the level of the systemic anticoagulation is a key determinant of the clinical outcome. The aPTT has been used to monitor the anticoagulant response of heparin, but it is extremely difficult and error prone to establish and maintain the therapeutic level of anticoagulation for an individual patient due to the complicated pharmacodynamics, patient-specific characteristics and the nature of heparin administration which creates many situations where medication errors and patient mismanagement can occur [(1).] The data from the United States Pharmacopeia MEDMARX database shows a total of 59,316 medication errors related to anticoagulants were reported from 2003 to 2007 and more than 17,000 involved heparin. Of the 556 errors (3.1%) resulted in harm to patients including seven deaths [(2).] Studies [(3)] have shown that a computer based system can increase the effectiveness of heparin administration.

To overcome the challenges and improve heparin management we have designed and developed the HNS system which automatically calculates IV heparin doses based on the patient's weight and aPTT results, electronically orders aPTT tests, and generates reminders to nurses through the use of built-in safety check logic to flag patients with abnormal pertinent lab results. HNS also checks drug interactions, duplicate orders and heparin allergy.

The objective of this project is to improve the efficiency and accuracy of the heparin administration through automating and monitoring the process by an in-house developed computer system.

Methodology: HNS is a web based computer application implemented in classic ASP technology that gets data from the Hospital Rules-Based System (HRBS) data warehouse, a relational Microsoft SQL database that integrates a near-real-time copy of clinical and administrative data from heterogeneous and distributed Mayo Clinic administrative and medical record systems.

HNS provides functionalities to allow the users to start or terminate the heparin treatment following prescribed goal aPTT and indication, and then periodically scans the data in the HRBS warehouse using predefined algorithm rules based on the weight-based heparin nomogram and selection criteria to determine if actions are needed.

Results: HNS has significantly reduced the incidents of heparin events more than10 fold over past 14 years. It has overcome the challenges of heparin management by using the following process:

- Allow the authorized users to start the heparin treatment by selecting the patient and a standard nomogram (high, intermediate or low intensity) with dose checking to the pharmacist order profile
- Calculates doses with decision-support for erroneous variables
- Initiates aPTT electronic order at 6 hours after starting or changing doses until a therapeutic dose is achieved (two consecutive values in range if within first 24 hours of HNS), then once daily
- Tracks and displays the aPTT order history and status
- Displays the anticoagulation and bleeding test results, such as patient's aPTT, hemoglobin and platelets in concise form to managing nurse
- Employs decision-support for spurious labs, potential heparinized lab samples, incorrect patient weights used, and potential side effects of heparin to the nurses
- Allows systematic analysis of recent changes and the three separate goal-based intensities of heparin used
- Serves as the interface of the quality data repository for analytics and quality improvement activities

Conclusion: HNS facilitates systematic support for and analysis of heparin therapy management. It provides an efficient workflow and safety solution to improve the efficiency and accuracy of heparin management by automating the dosing and lab ordering. It significantly reduces the opportunities for the errors to occur through the use of built-in automatic aPTT test ordering, nurse-reminders, abnormal lab test flags and decision support mechanism.

Alerting System for Patients with Advanced Multiple Sclerosis

Yihua Li[1], Dorothy W. Curtis, M.Sc.[1], Esteban J. Pino, D.Sc.[2], Pablo Aqueveque, D.Sc[2],
[1]Computer Science and Artificial Intelligence Laboratory, MIT, Cambridge, MA,USA;
[2]Department of Electrical Engineering, Universidad de Concepción, Concepción, Chile

Overview

This abstract presents the design and implementation of the software components of a new non-invasive monitoring system for people with Advanced Multiple Sclerosis. The proposed system addresses issues in advanced MS such as low mobility and heat sensitivity, and consists of a central monitoring station for nurses and individual monitoring systems for each patient. It gives suggestions and generates alarms to the patients and aims to help caregivers in assisted living facilities provide better supervision. Our poster will show preliminary results from experiments testing the effectiveness of our tilting alerts and our heat exposure alerts.

Introduction

Multiple sclerosis (MS) is an autoimmune disease that affects the central nervous system. Patients often suffer from problems such as fatigue, low mobility and pressure ulcers. In addition, they might experience a temporary worsening of their symptoms when they are outside in hot and humid weather for long duration. To encourage patient independence and comfort and also help caregivers to improve patient care and supervision, a multi-sensor monitoring system for people with advanced Multiple Sclerosis has been designed and implemented[1]. Several non-invasive sensors are deployed on an electric wheelchair and they constantly collect Ballistocardiogram (BCG) signals, pressure signals, accelerometer data, ambient temperature and relative humidity. The acquired data is stored in PostgreSQL database in a laptop mounted on the wheelchair. We further develop the system and build software components that utilize the data captured by the sensors to generate alarms related to the MS patient health status.

System Description

The monitoring system consists of three main parts: (1) the laptops in individual wheelchairs; (2) a central monitoring station; (3) and a webserver that links the two and transmits the data from the laptops to the central station via a wireless network. The software program on each individual wheelchair analyzes the sensor data and generates audio alarms for the patient. These audio alarms need to have some variety since the patient might become accustomed to a particular alarm and ignore it. The programs can work in a standalone mode for alerting the patients and we also implement a GUI with PyQt that allows caregivers to quickly assess patients' degree of exposure to heat.The central monitoring station is designed mainly for the caregivers to monitor patients' health condition remotely. The user interface (UI) displays information relating to patient's health status, and gives visual alarms to the nurses when necessary. We make the UI web-based to provide real-time display and develop it with techniques and technologies such as html, javaScript and jQuery library.

Alert Generation

The system generates alerts to prevent excessive heat exposure. The detection parameter is a cumulative heat index, computed from temperature and humidity over time. The alarm generation threshold is chosen by the caregiver. Initial alerts tell the user how much heat exposure they have had and how long they can stay outside. Later alerts remind the user that he/she should return indoors. Alerts are also used to remind patients when they should tilt their wheelchairs to prevent pressure ulcers. The schedule of these alerts is determined by the caregiver.

Conclusion

We have designed and developed the software components of the monitoring system that generates alerts relating to MS patient's health status from the sensor data. These alerts, together with the relevant health information, will help prevent risk conditions for the MS patients and assist the nurses to give better patient care. We plan to deploy and test the final complete system at The Boston Home, Dorchester, MA.

Identification of Common Concepts for Clinical Decision Support and Mapping to the Health Level 7 Virtual Medical Record Data Model

Yanhua Lin, PhD, Brandon Welch, PhD, Tyler Tippetts, BS, Polina Kukhareva, MS, David Shields, MS, Catherine Staes, BSN, MPH, PhD, Vijay Kandula, MD, Bruce Bray, MD, Kensaku Kawamoto, MD, PhD

Department of Biomedical Informatics, University of Utah, Salt Lake City, UT

Abstract

Standard terminologies are a critical resource for enabling interoperable clinical decision support (CDS). However, the enormous quantity of concepts available in these terminologies makes it imperative to identify concept subsets relevant for CDS. To address this problem, a domain expert-driven approach was used to systematically identify concepts relevant for CDS, and these concepts were mapped to relevant attributes of the HL7 Virtual Medical Record CDS data model. The resource developed is freely available through www.opencds.org.

Introduction

A key challenge for clinical decision support (CDS) is the difficulty of scaling CDS across institutions.[1] Standard terminologies can facilitate the achievement of interoperable, cross-institutional CDS by allowing the mapping of local data representations to standard concepts used by the CDS knowledge base. Currently, a standardized data model for CDS is available in the form of the HL7 Virtual Medical Record (vMR) standard. Also, many standard terminologies such as SNOMED-CT, RxNorm and LOINC are available for use in CDS. However, the sheer volume of concepts in these terminologies can make it challenging to ensure that different CDS implementers choose the same concepts in their respective implementations. For example, SNOMED-CT alone includes over 300,000 concepts. The objective of this effort was to identify a subset of concepts from standard terminologies likely to be relevant for CDS, so as to form the foundation of a more manageable corpus of concepts used commonly across CDS implementations and mapped to relevant attributes of the HL7 vMR data model.

Methods

We systematically analyzed all coded data elements in Release 1 of the HL7 vMR standard and then developed a strategy for identifying the concepts most relevant for CDS in each of these areas. This strategy involved two steps: the manual identification of candidate concepts by the project team followed by concept review by a physician informaticist. For example, in the first step, we identified candidate problems from the CORE Problem List subset of SNOMED-CT[2] and candidate laboratory results from LOINC's "top 300" orders.[3] We also reviewed value sets available in the Public Health Information Network Vocabulary Access Distribution System (PHIN VADS) and included value sets for Encounter, Problem Importance, Severity, Gender, and Race, for example. In the second step, a physician informaticist (VK) reviewed each concept in the candidate set and identified those that had a reasonable likelihood of being useful for CDS purposes in a typical clinical care setting. In addition, we included concepts from quality measurement specifications, such as Surgical Care Improvement Project (SCIP) and Healthcare Effectiveness Data and Information Set (HEDIS) measures. Each of these concepts were then uploaded into an Apelon DTS terminology server as CDS-related concepts managed by the OpenCDS initiative (www.opencds.org).

Results

Approximately 2,200 clinical concepts were identified spanning 74 vMR attributes, including Adverse Event Type, Encounters Type, Goal Type, Observation Focus, Problems, Procedures, Medications, and Supplies. A terminology mapper was also developed to map concepts from various standard terminologies (e.g. SNOMED-CT, ICD9, and LOINC) to this CDS concept taxonomy. These concepts and tools are now being used in the OpenCDS initiative and are freely available to this collaborative open-source community.

Conclusion

A CDS concept taxonomy can facilitate the use of standard terminologies to enable scalable and interoperable CDS.

Iterative Participatory Design of Health Information Technology for Underserved Populations

Elizabeth A. Linton[1], Tina Kurtz, R.N[1], Kim M. Unertl, PhD[1]
[1]Vanderbilt University, Nashville, TN

Abstract

We describe how researchers working with the Vanderbilt-Meharry-Matthew Walker Sickle Cell Center for Excellence (VMMW) applied iterative participatory design (IPD) of health information technology to transition paper-based sickle cell health management tools into electronic tools within an EHR. IPD proved labor intensive, but yielded high usability and stakeholder satisfaction.

Introduction

(IPD) is "a process of mutual learning by designers and domain experts (users) ... [aimed] at changing the users' work practices ... [by introducing] information systems" [1]. Research shows that health information technology (HIT) that interrupts workflow or is confusing to use suffers from low uptake. End users also develop ad-hoc workarounds with unintended consequences, and systems may fall short of achieving intended purposes [2]. An iterative participatory design (IPD) approach to product development has the potential to help avoid these pitfalls.

Methods

We conducted a qualitative study of HIT's place at the Vanderbilt-Meharry-Matthew Walker Sickle Cell Center for Excellence (VMMW), documenting over 250 hours of interactions between patients, healthcare providers, and technology. Members of the research team shadowed health care providers during patients' appointments and in the doctors' office as notes were documented. We paid special attention to issues arising around the electronic health record (EHR), workflow, communication, and decision-making. Healthcare team members identified translating paper forms into the electronic medical record as a key area for improving workflow decreasing EMR workarounds. Figure 1 summarizes the four-stage IPD process used during the project.

1) Communally ***[RE] EVALUATE*** strengths and weaknesses of patient care current tools	2) ***[RE] DESIGN*** working model of tool to address weaknesses and incorporate pre-existing strengths
4) ***[RE]TEST*** privately, during team meetings, and during real clinic visits to verify and validate the tool	3) ***[RE] BUILD*** tool only after establishing clear but reasonably flexible usage criteria and requirements

Figure 1. Iterative Participatory Design with VMMW

Results

Clinic observation revealed that the sickle cell healthcare providers heavily employed paper forms like a Sickle Cell Pain Action Plan as EHR workarounds. VMMW providers identified these forms as a necessary aspect of patient care that could be improved if available within the EHR. IPD informed the successful transition of seven sickle cell health management tools from paper forms to computerized tools in the EHR. Resources needed to facilitate IPD include: buy-in from both the informatics and healthcare teams, an individual assigned to build the tools, and a regular venue where drafts are communally tested and edited. The electronic forms addressed difficulties associated with paper versions including: multiple editions in use simultaneously, illegible scanned versions in the EHR, and difficulty accessing care plans for patients outside the clinic setting. Computerized documents were used ~400 times; feedback from revision sessions (about 3 per form) indicated they were well received.

Conclusion

Iterative participatory design allows patients, medical team members, and informatics teams to partner in improving HIT monitoring and delivery. However, IPD's labor intensive process is a potential limiter of widespread use. Finding routes to refine the efficiency of IPD in practice (especially in limited resource settings) could make this approach valuable in future biomedical informatics research.

Developing Clinical Decision Support for Direct Use by Patients: Challenges and Lessons Learned from Symptom Management in Cancer Patients

David F. Lobach, MD, PhD, MS[1]; Janet L. Abrahm, MD[2]; Donna L. Berry, RN, PhD[2]; Michael S. Rabin, MD[2]; Ilana Braun, MD[2]; Manan Nayak, MA[2]; Mary E. Cooley, RN, PhD[2]
[1]Religent Health and Duke University Medical Center, Durham, NC; and
[2]Dana-Farber Cancer Institute, Boston, MA

Abstract

One approach for engaging and empowering patients is through the development of clinical decision support (CDS) tools designed for direct use by patients. In this project we assessed the feasibility of creating CDS tools for the self-management of symptoms in cancer patients. Patient safety and health literacy issues were addressed. Additionally, in order to provide suggestions for symptom relief, recommendations for medication therapy were structured to reference existing clinical management practices of the overseeing clinician.

Introduction

Relatively little is known regarding CDS for patients with cancer and few studies have described CDS tools for direct use by cancer patients[1,2]. In these studies, the focus of the CDS was to identify the presence or absence of a specific symptom through an algorithm with a single decision node followed by general recommendations for managing that symptom[1] or through heavy reliance on interactions with clinical personnel[2]. The literature provides no precedents for developing more complex self-management algorithms for cancer patients. The goal of this project was to understand the needs of patients with regard to CDS, along with identifying effective mechanisms for delivering patient guidance for self management of their symptoms and direction for when to call their clinicians.

Methods

The first phase of the project was to understand patient and clinician perspectives regarding symptoms and quality of life experiences during cancer treatment and the second phase was to develop resources such as CDS tools for direct use by patients. In phase 1, patient and clinician perspectives were ascertained through focus groups and semi-structured interviews. Participants included a total of 57 adult patients who had received cancer treatment within the past six months and 51 clinicians who provided care in ambulatory oncology settings. For phase 2, oncologists, palliative care specialists, and nurse scientists drew from evidence-based resources and worked with CDS experts to develop computable algorithms that would enable patient self-management for pain, constipation, and nausea and vomiting. The clinical algorithms were converted to patient friendly language and an interactive format in order to assess usability and comprehensibility through focus groups, interviews, and patient-directed think aloud sessions.

Results: Challenges and Lessons Learned

Significant challenges were identified in developing CDS tools for symptom management in cancer patients. A primary concern was maintaining patient safety by identifying potential serious or life-threatening causes for symptoms and directing patients to seek contact with their clinicians. Accordingly, all three patient CDS algorithms began with the identification of "red flags" that would necessitate that the patient exit the CDS tool to seek clinician guidance. A second challenge was to support users across a wide breadth of health literacy. To address this challenge, we developed content at a fifth grade reading level and provided descriptions and educational information that users could elect to review or skip based on perceived information needs.

In order to provide medication-related advice, we sought to ensure that recommendations were evidence-based and grounded in therapies approved by the clinician overseeing a patient's care. Accordingly, we inquired whether a patient was using a particular therapy or if he had been prescribed that particular therapy. If he was not using the therapy, he was advised to use it. If he had not been prescribed the recommended therapy, he was advised to contact his clinician and inquire if this therapy could be appropriate.

Conclusion

Through this project, we have shown an approach for providing CDS for patient self-management in cancer care including provisions for patient safety and recommendations for medication use for symptom control.

Towards a Representation Format for Sharable Self-Monitoring Data

Guillermo H. Lopez-Campos, PhD, Manal Almalki MSc, Fernando Martin-Sanchez, PhD
Health and Biomedical Informatics Centre, The University of Melbourne, Melbourne, Australia;

Abstract

Self-monitoring devices and apps are becoming increasingly popular for research purposes. In the context of biomedical research, metadata associated with experimental studies has become a key element to make sense of heterogeneous and very complex sets of data. In this work we discuss the need for a reporting guideline to describe data and metadata generated in self-monitoring experiments in a standardized way. This data representation format could enable the reproducibility of experiments and improve the interpretation of data collected using "self-monitoring" strategies.

Introduction

In recent years advances in technology have enabled the development of a vast amount of increasingly miniaturized sensor devices and mobile apps that can be used for monitoring an increasing number of features such as physical activity, physiological parameters, behaviour or exposure to environmental factors following a "self-tracking" or "self-monitoring" approach. These approaches have been successfully used in different scenarios in clinical research (i.e. self-tracking of physical activity[1]). Although they represent an opportunity to gather highly valuable patient-generated data in a continuous manner, also pose challenges for biomedical informatics due to the need to integrate new data sources with different formats from different devices. Another important issue that needs to be addressed is the interpretability of those data. By providing the appropriate metadata associated with the measurements we can increase the usefulness of these data for clinical research

Methods

Based in previous successful experiences in bioinformatics with the development of Minimum Information Guides for different research areas[2,] we propose the development of a similar guideline for the use of self-monitoring methodologies for research purposes.

The proposed guideline is structured around the ISA (Investigation-Study-Assay) concept and uses five major axes to describe the monitoring activities. The first axis covers a experimental description of the experiment design. The second axis focuses on the description of the "sample" used in the study, either a whole individual (i.e. for physical activity measurements) or an element of the body. The third axis describes the annotation and description of the device/s used during the monitoring process. The fourth element captures the "measurement", that is what is measured and the procedures related with how "sample" and "device" interact with each other. Finally the fifth and last axis focuses in the collected data and their annotation. During the annotation of each of these axes, the use of appropriate existing ontologies and controlled vocabularies is encouraged and required.

Conclusion

This representation format should be firstly adopted by the research community to ensure that data collected through "self-tracking"/"self-monitoring" can be compared and easily shared. As it happened before with other minimal information guidelines its adoption would then enable and support the development of public data repositories for these studies ensuring data accessibility and enabling meta-analyses. Device manufacturers could be involved in the development of the guideline making their data formats compliant with the proposal to ensure compatibility across platforms. Finally, the existence and adherence to such minimal information guideline could facilitate data exchange between the self-trackers community and researchers in a structured way and providing enough metadata to the researchers to apply those data enlarging annotated datasets for research.

Physician Satisfaction With Computerized Order Entry

Paul Loubser; MB, ChB; University of Texas Medical School at Houston, Houston, Texas
Val Hooper; PhD, MBA, Hoer Bibl Dipl, BA; Victoria University of Wellington, New Zealand

Introduction: Computerized e-ordering is rapidly becoming the norm in many healthcare institutions. The Department of Anesthesiology implemented such a system one year ago. We elected to determine the success of this system by surveying user satisfaction, i.e. the faculty and residents, with the system. The factors that contributed to user satisfaction were assessed to ascertain which exerted the greatest influence on the users. The relative importance of each attribute of the system would provide an indication of where developers of such systems would need to focus their attention in order to ensure greatest satisfaction with the system in the future.

Methods: A 10 question 'satisfaction' survey was conducted amongst 128 faculty and residents of which 39 faculty and 38 residents responded. Structural equation modelling (SEM) was used to analyse the data. All the respondents' data were analysed together first and then the residents and faculty's data were analysed separately. The research model was based on the Technology Acceptance Model (TAM) (Davis et al., 1989) and extensions thereof (Venkatesh & Bala, n.d.; Venkatesh & Davis, 2000; Venkatesh et al, 2003).

Results: The R^2 in each instance represents the extent of the variance in the relevant dependent variable attributable to the independent variables. Thus, 'reducing medication errors' was only responsible for 1.2% of the ability to render patient care in the combined sample, 3.5% amongst faculty only, and a much larger 13.4% amongst residents. Together, the ability to render patient care, its user friendliness, and the available IT support, contributed to a large 76.9% of the variance in the satisfaction of the combined sample of the users, 78.5% amongst faculty and 75.7% amongst residents. In the combined sample, the user satisfaction, together with the perceived receptivity to the system by others, accounted for 19.8% of the variance in the extent to which expansion of the e-ordering system to other services was welcomed; 18.4% of the variance amongst faculty; and 17.6% amongst residents. The paths from IT support to satisfaction, and from satisfaction to welcoming expansion to other services were not significant, even though the paths between IT support and satisfaction for the faculty, and between satisfaction and welcoming expansion were strong enough. For the combined sample, the paths between rendering patient care and satisfaction, between user friendliness and satisfaction, and between receptivity and welcoming expansion, were particularly strong and significant. The attributes of the e-ordering system that had been identified as contributing to a large percentage of the impact on satisfaction with the system were user friendliness and the ability to render patient care. The user friendliness of the system was the overwhelming attribute that influenced the satisfaction with the e-ordering system. With a similar impact on satisfaction amongst the combined sample, and slightly less so amongst the faculty and residents, the ability to render patient care was minimally influenced by the perceived reduction in medication errors.

Conclusion: The importance of the user friendliness and the ability to facilitate rendering of patient care emerged as the main attributes sought from such a system. For the system to be rolled out to other services, these are the two main attributes that influence system acceptance and adoption. IT support did not seem to be a significant factor; it may be taken for granted by users. Although the satisfaction did not demonstrate a strong influence on the welcome of expansion of the system to other services, certainly the perceived receptivity of the system by colleagues played an important role in influencing that welcome to expansion. In addition, there were probably many other considerations such as the type of system and the type of work, plus the available resources, and the mindsets of the users of other systems, which would play a role. However, future research will explore the preparedness of the users of other services to adopt such an e-ordering system.

Using Element Words to Generate (Multi)words for the SPECIALIST Lexicon

Chris J. Lu, Ph.D.[1, 2], Destinee Tormey[1], Lynn McCreedy, Ph.D.[1], and Allen C. Browne [1]
[1]National Library of Medicine, Bethesda, MD; [2]Medical Science & Computing, Inc., Rockville, MD

Abstract
The SPECIALIST Lexicon has been distributed annually by the National Library of Medicine (NLM) since 1994. Lexical records are used for Part-of-Speech (POS) tagging, indexing, information retrieval, concept mapping, etc. in many Natural Language Processing (NLP) projects, such as Lexical Tools, MetaMap, SemRep, UMLS Metathesaurus, and ClinicalTrials.gov. This paper describes a new systematic approach to identify single words and multiwords from MEDLINE through the use of element words. Element words are lowercase single words without punctuation and are not stopwords. Results show an accelerated growth of the Lexicon, particularly an increase in multiword records. Hence, improvement in recall or precision can be anticipated in NLP projects using the SPECIALIST Lexicon and its applications.

1. Introduction – The NLP SPECIALIST Lexicon and LexBuild

The Lexicon is built by linguists through a web-based computer-aided tool, LexBuild [1]. Element words are a resource used by linguists to 1) add new Lexical records if no exact/close match is found in LexBuild; 2) update existing lexical records if related records are found by close match. Multiwords that contain these new element words are reviewed through the Essie search engine [2], Google Scholar, dictionaries, etc. during the LexBuild process.

2. (Multi)words by New Element Words from MEDLINE

For (multi)word inclusion in the Lexicon from MEDLINE, we developed this system: 1) retrieve element words through tokenization (lowercase, remove punctuation, and use space as word boundaries) from MEDLINE titles and abstracts; 2) categorize these element words by type: single words in the Lexicon (e.g. diabetes), not a single word but parts of multiwords already in the Lexicon (e.g. mellitus), numbers (e.g. five), digits (e.g. 5), non-words (e.g. 3h), and new element words (e.g. cdh); 3) calculate word count (WC). New element words with high frequency (WC >= 1500) are retrieved automatically for review to cover single words (97.58%) and multiwords from MEDLINE. For example, the new element word "cdh" (9983 WC) leads to 44 new lexical records with base forms in 78 single words (e.g. cadherin1) and 23 multiwords (e.g. "chronic daily headache").

3. (Multi)words by Existing Element Words from MEDLINE

This system also retrieves candidates of new multiwords from MEDLINE for (existing) element words: 1) Generate high frequency n-grams of length 1-5 from MEDLINE. The low frequency n-gram terms are filtered out if the associated (n-1)-gram terms have low WC of normalized form (NWC). 2). N-grams are normalized by abstracting away from genitive, punctuation, and case so that different forms of a same term are grouped together for further analysis. 3). Generate new candidate multiwords by applying a rule-based system to filter out invalid multiwords from n-grams. These rules exclude (normalized) n-grams that exist in the Lexicon, start/end with a preposition/auxiliary/modal/conjunction, end with determiner/acronym in a parenthesis, etc.. Document count, WC, and NWC are also used to filter out low frequent error prone n-grams (e.g. typos). Further development of these rules is intended to increase the precision of candidate multiwords. 4). These new candidate multiwords are reviewed by linguists, who add grammatical and lexical variant information, yielding completed Lexicon records. For example, the element word "mellitus" was identified in 24 multiword lexical records in the previous Lexicon release (2014). In our new approach, a candidate list (532) is retrieved automatically from 1304 n-gram terms containing "mellitus" after filtering out ~60% of invalid words. This list is then mapped into 390 normalized forms to ease the final review process in linguistic contexts. As a result, 36 new lexical records with base forms in 9 single words (including, actually, "mellitus") and 41 multiwords (e.g. "diabetic mellitus") have been added, a 150% growth from Lexicon.2014. In addition, 7 other associated existing records with 10 multiwords have been updated for spelling variants and acronym expansions. Please refer to the Lexicon web site for details [3].

4. Conclusion

There are 477K lexical records with 1.69M forms in the 2014 Lexicon release. About 47.7% (418K) of unique forms (875K) are multiwords. Multiwords are an essential ingredient and play a key role in the success of NLP tasks. This new system enhances the Lexicon's coverage, especially on multiwords. We expect the growth of multiwords in future Lexicon releases to reach the estimated value (50%) through this system [4]. This new system encourages rapid growth of single words as well as multiwords in the Lexicon, which will ultimately provide better NLP results.

De-identified clinical research data warehouse in a Korean tertiary hospital

Yong-Man Lyu[2], Soo-Yong Shin, PhD[1,2], Yongdon Shin[2],HyoJoung Choi, RN[2], Jihyun Park[2],Eun-Ae Kang[2] , Woo-Sung Kim, MD, PhD[1,3],Chang-Min Choi, MD, PhD[23],Yu Rang Park[1], JaeHo Lee, MD, PhD[1,2,4]

[1]Department of Biomedical Informatics; [2]Office of Clinical Research Information; [3]Department of Pulmonary & Critical Care Medicine; [4]Department of Emergency Medicine, Asan Medical Center, Seoul, Korea

Abstract

Research environments are emphasized toward provisions of ethics in Korea. To comply with governmental regulations, all identifiers of patient must be removed from Electronic Medical Record. Asan Medical Center (AMC) have developed a de-identification clinical research system, called ABLE (Asan BiomedicaL research Environment), including cohort discovery, de-identified chart review, and data extraction tool. ABLE has about 4M registered patients with over 600M orders, 715M lab results, 257M clinical notes, and 4M DICOM images.

Introduction

According to the revised regulations in Korea, research environments are emphasized toward provisions of ethics in order to protect patients' privacy. This is in response to growing interest from researchers who want to use clinical data for study purpose. To comply with Korean regulations, AMC has developed a de-identified clinical research system named ABLE in accordance with domestic and international research regulations.

Method

Based on the previous studies (1, 2), we have developed ABLE in collaboration with inbrein company. We defined 19 internal identifiers and developed de-identification methods. The de-identification system achieved 99.87% accuracy and 96.25% recall for validation dataset which composed 5,000 clinical notes of 33 different note types (2). We tried to remove identifiers in PACS images as well as EMR. For the convenience of researchers, we developed three tools such as cohort discovery, de-identified data review and data extraction. All tools were developed using Microsoft.NET framework and C#. MS parallel data warehouse version 2 was chosen as data warehouse appliance with MS SQL Server 2012.

Result and Conclusion

ABLE system includes the about 4M patients' data since 1989. As a result, ABLE can search over 600M physicians' orders including over 191M medication orders. Also it can search over 715M laboratory results. The de-identification chart review tool can review over 257M clinical notes of 892 different kinds of clinical notes, over 3M CT images and over 1M MR images. The data extraction tool also supports keyword search within clinical notes. By developing an anonymising system, we have greatly increased the opportunity to use clinical data for study purposes under the new research regulations. The system described herein represents an important reference toward provisions of research ethics and protection of patient privacy in Korea.

Use of Natural Language Processing in Terminology Coverage Analysis

Sina Madani, MD, PhD[1], Dean F. Sittig, PhD[2], Michael M. Riben, MD[1]
[1]The University of Texas MD Anderson Cancer Center, Houston, TX
[2]The University of Texas School of Biomedical Informatics at Houston, Houston, TX

Abstract
Interface terminologies designed by vendors have been used to facilitate provider friendly data entry at the point of care within healthcare organizations. While these terminologies with backend mappings to standard vocabularies may be advertised for data integration and decision support benefits, the content coverage should be evaluated against existing healthcare provider vocabulary usage. We investigated two interface terminologies against our clinical narrative repositories using natural language processing in order to evaluate the term coverage.

Introduction
Standard terminologies are rigid by nature and designed to be consumed by computer applications. On the other hand, interface terminologies are created to facilitate provider friendly term entry at the point of care while maintaining back end mappings to standard vocabularies. Many third party vendors are now producing such terminologies. However, health care organizations are unique in terms of their clinical service and documentation contents. Therefore, third party interface terminologies should be evaluated, in terms of content coverage, and customized or extended before and after acquisition respectively. We used Natural Language Processing (NLP) methods in order to evaluate two interface terminologies against our clinical narrative contents.

Methods
Clinical notes were extracted from MD Anderson Cancer Center repositories and preprocessed for identification of section headers related to the Past Medical History and Problem List. An NLP pipeline was developed and contents of the extracted section headers were processed by MetaMap with restriction to the "Disorders" semantic group, including "neoplastic" semantic type for cancer related concepts. XML outputs were converted to Resource Description Framework (RDF) and loaded into a local instance of AllegroGraph® triple store. The 50 most frequently occurring concepts were extracted using semantic queries and evaluated by a trained physician for cancer and non-cancer related terms against two interface (provider friendly) terminologies from Health Language, Inc. and Intelligent Medical Objects, Inc.

Results
A total of 291,139 Past Medical History (group 1) and 232,154 Problem List related section headers (group 2) were identified from the corpora of 420,557 clinical narratives. Under these sections, 2,525,527 non-cancer related terms (27,321 concepts) from group 1 and 158,392 cancer related terms (676 concepts) from group 2 section headers were extracted. An average of 6.18 and 6.36 synonyms per concept were calculated for group 1 and 2 respectively. Content coverage evaluation results within top 50 concepts (by frequency) are summarized in table 1 below.

	Non-Cancer Items		Cancer Items	
Total terms	662,217 (50 concepts)		148,278 (50 concepts)	
Unique terms	318 (50 concepts)		309 (50 concepts)	
Content Coverage	Terminology 1	Terminology 2	Terminology 1	Terminology 2
Number of unavailable unique terms	59	82	72	54
Percentage of total term coverage	88.67%	81.61%	92.97%	90.45%
Unavailable terms in *both* terminologies	39 (9.72% of the total terms)		32 (3.4% of the total terms)	

Table1. Term coverage analysis between the two provider friendly (interface) terminologies

Discussion
Although we didn't find any significant difference in content coverage between the two interface terminologies, the result of this study can be used for gap analysis and enable terminology providers to enrich their vocabularies. Such an approach could also enhance the usability of third party content sets that are prepared more toward consumer needs and create an opportunity for participation in the domain-specific and/or provider-friendly terminology development process.

Workflow-based modeling of cancer care trial protocols

Aisan Maghsoodi[1,2], Anca Bucur, PhD[2], Paul de Bra, Prof, Dr[1], Norbert Graf, Prof, Dr[3]
[1] Technical University of Eindhoven, Netherlands; [2]Philips Research Europe, Netherlands;
[3] Saarland University, Germany

Abstract

A large number of cancer patients are treated in the context of clinical trials, for which free-text evidence-based protocols aiming at standardization of care delivery exists. We propose a workflow-based representation model for cancer trial protocols, so that information relevant to each active process can be directed to the intended role. This modelling approach enables monitoring patients with respect to the protocol-based care path, as well as retrospective analysis of care process to understand deviations and sources for delays and bottlenecks.

Introduction

Research on computer interpretable clinical guidelines has largely focused on individual tasks rather than complex processes of care which are extended in time[1]. CDS systems have mainly focused on using guideline knowledge for decision making at a time point. We have focused on cancer care trial protocols (CCTP) which contain detailed description of care methods like complex treatment plans over a period of time delivered in different care settings, along with study-related processes to be adhered to, such as reporting. CCTPs are meant to standardize trial-based care processes across participating institutions. Our modeling methodology enables generation of CCTP-based systems for monitoring the patients' progress and providing next step guidance for clinical actors in different setting by aggregating and presenting only the relevant role, activity and process-specific information spread in the document. Analysis of the execution of such a system will lead to better comprehension of the problems. The frequent deviations can be indicators of problems in protocol that can trigger new hypothesis for research.

Methodology

We investigated protocols from two different domains: Wilms Tumor (SIOP), Leukemia (AIEOP-BFM ALL) in order to find similarities of CCTPs and to test the model's ability to be generalized. For each cancer domain, common processes and the critical path for all centers are identified. Our model includes an entity model, such as medical named entities, trial entities and their specific attributes. The second part includes care and study-related processes, activities and their context attributes. Domain-specific processes, their order, dependencies, resources and events were represented using business process modeling notation (BPMN) and checked with clinicians for validation.

Using BPMN CCTPs can be intuitively represented as collection of linked processes in their context such as resources, communications, events that can occur such as errors, exceptions, delays, local adaptations and activity or entity states.

To provide link back to original text as evidence for activities in the model, CCTP was processed using NLP and techniques together with SNOMED and UMLS annotations.

Conclusion

This methodology enables directing tasks, pre and post conditions, and communications as well as evidence to the intended role in the care process. Also, it caters for locating the patient in the care process.

The CCTPs models generated can be shared at the level of domain elements and main processes. By identifying the critical paths that need to be followed by all canters in all countries, local adaptations can be addressed by allowing non-prohibited changes. The modeled CCTP is adaptable to updates as the changes can be easily assigned to its related process and affected process elements be tracked using the model. Inter-operability with EHR has not been the focus since many participating trial centers do not obtain an EHR, but using standard vocabularies in entity model provided hooks for mapping the data model. Colleting the event logs after the execution of enables retrospective analysis of deviations and delays. The methodology can be communicated to the authoring committees to be used in authoring templates which can further facilitate the automatic model element extraction.

A Usability Analysis of a Fuzzy Match Search Engine for Physician Directories

Mahnke, Andrea[1], MS; Baker, Kate[1], MA; Krause, Tim[2], PhD; Christian, Courtney[2]; Hale, Katy[2]; Kautz, Karissa[2]; Mueller, Elizabeth[2]; Majid Rastegar-Mojarad[1], MS; Waltonen, Stuart[3], PhD, ABPP; Kortenkamp, Sarah[3], PhD; Lin, Simon[1], MD
[1]Marshfield Clinic Research Foundation, Biomedical Informatics Research Center, Marshfield, WI
[2]University of Wisconsin Stevens Point, Stevens Point, WI
[3]Marshfield Clinic, Neuropsychology, Marshfield, WI

Background:
A search engine to find physicians' information is a basic but crucial function of a healthcare provider's website. Inefficient search engines returning no results or incorrect results can lead to patient frustration and potential customer loss. A search engine that can that handle the misspelling and spelling variation of names is needed, as the United States has culturally, racially, and ethnically diverse names. This search engine could also have broader implications for the other many types of searches necessary in the medical setting.
Objective:
The Marshfield Clinic web site provides a search engine for users to search for a physicians' name. The current search engine provides auto-completion function but requires exact match. We observed 26% of the searches yielded no results. The goal is to design a fuzzy match algorithm to aid users to find sought physician more effectively and efficiently. A second goal is to then conduct usability testing on both the current web site and fuzzy match search engines to see if differences exist and where.
Methods:
Instead of an exact match search, we used a fuzzy algorithm to find similar matches for searched term. In the algorithm, we solved three types of search engine failures: "Typographic", "Phonetic spelling variation", and "Nickname". To solve these mismatches, we used a customized Levenshtein distance calculation that incorporated Soundex coding and a lookup table of nicknames derived from US census data. Usability testing was conducted in collaboration with local university students as part of their semester independent study project. Staff neuropsychologists were also consulted regarding study design. A pilot usability study was conducted with a convenience sample of undergraduate students, n=10 for the existing web site search engine and n=9 for the fuzzy match search engine (total n=19). After a verbal consent, participants were given a scenario where they had an injury and wanted to consult a physician they had seen in the past. Participants were shown a head shot of a provider with the name, specialty and office phone number listed next to the photo for 10 seconds. An audio pronunciation of the name was also provided. The physician name chosen was considered a relatively harder name to spell. They then viewed a 10 minute video categorized as entertaining and distracting. They were assigned one of the two search engines and asked to find the physician they saw at the beginning of the session and verbally state their appointment phone number. Participants were given five attempts to correctly find the physician. Attempts, rather than time on task were used to compare because the two search engines reacted at different speeds. Audio, screen and participant face recording were captured using Morae software. Participants were entered into a raffle for an iPod shuffle for their time. A system usability scale (SUS) survey was completed after the test session.
Results:
Participants were measured on task success (0=completed successfully, 1=completed with difficulty, 2=failed to complete), recall (did they provide an answer) and precision (did they provide the correct answer). Task success Marshfield Clinic/Fuzzy Match: 0, 30%/78%; 1, 30%/11%; 2, 40%/11%. Recall Marshfield Clinic/Fuzzy Match: 60%/88.89%. Precision Marshfield Clinic/Fuzzy Match: 83.33%/100%. SUS score Marshfield Clinic/Fuzzy Match 78.50/79.25.
Conclusion:
The results of the pilot test suggest that the Fuzzy Match search engine is better at helping people find health care providers than the existing search tool featured on the Marshfield Clinic Web site. An additional study with a larger sample size will provide better information regarding the search recall and accuracy of the Fuzzy Match search engine.

An Evaluation of Computerized Medication Alert Override Behavior in Ambulatory Care

Nivethietha Maniam[1]; Sarah P. Slight, MPharm, PhD, PGDip[2,3]; Diane L. Seger, RPh[1]; Mary Amato, PharmD, MPH[2,7]; Julie M. Fiskio,[1]; Dustin McEvoy[1]; Karen C. Nanji, MD, MPH[4,5]; Patricia C. Dykes, PhD, RN, FACMI[2,4]; David W. Bates MD, MSc.[1,2,4]

Abstract: *Alert fatigue may compromise patient safety during the prescribing process by overburdening providers with unnecessary alerts. Our goal was to identify providers with a high inappropriate override rate and conduct academic detailing sessions regarding their override behavior. This study identified factors that influenced physicians' overriding behavior and identified areas where alert functionality could be improved to create a safer, more efficient computerized decision support system.*

Background: While evidence suggests that computerized decision support (CDS) increases safety and quality of care, understanding how physicians respond to CDS alerts is a critical factor in achieving meaningful use of electronic health records (EHRs). Application of the CDS alert functionality is variable among providers and we continue to observe a high level of medication alert overrides for many prescription domains. While many overrides are justified clinically, some are not, and it is important to be able to reach out to those providers who are not prescribing optimally and understand their reasons for overriding alerts.

Methods: All Level 2 alert overrides that required providers to give a coded reason for overrides at the time of prescribing were downloaded between January 2009 and December 2011 in the outpatient primary care setting. We limited our sample to providers who had received 20 or more alerts (opportunity to override) in each of the prescribing domains (drug-drug interaction, drug-allergy interaction, renal suggestion, age-based, duplicate drug, and formulary substitution alerts) and calculated the number of times each provider overrode these alerts. Of the 725 providers eligible for the study, those with a high inappropriate override rate (above 75% within a specific domain or overall) were targeted for academic detailing sessions. The sessions were conducted by a research pharmacist or physician trained in effective counter-detailing techniques and tailored to each provider's overrides. Graphical materials including performance level data, provider-specific inappropriate overrides and supporting evidence-based summaries were used as the basis for a two-way discussion. A robust analysis of the data was carried out and general views on alert functionality and specific prescribing behavior were identified.

Results: We conducted 23 academic detailing sessions across primary care clinics affiliated with Brigham and Women's Hospital and Massachusetts General Hospital. We identified seven high level content categories: clinical satisfaction, clinical utility and relevance, variant user knowledge, impact on clinician reviewing process, patient preferences, current alerting tool challenges, and considerations for the future. Overall, providers were generally favorable towards the alerts and felt they were helpful in identifying possible adverse interactions. Many providers found that the clinical relevance of the alerts could be improved by including more detailed data such as the magnitude of risk, suggesting alternate treatments, providing recent laboratory values, and up-to-date reference material. Many participants reflected on how they failed to provide a valid override reason because they found the alerts time-consuming and disruptive. Creating a more patient specific alerting tool was recognized as a future area of focus. Limitations of the existing EHR infrastructure such as inaccurate medication and allergy lists were identified as contributing to unnecessary alerts.

Conclusion: Many providers were unaware of their relatively high rate of overriding and this study allowed providers the unique opportunity of objectively assessing their prescribing behavior. Key issues that emerged from the sessions included the perceived risk to physician autonomy in decision-making, the increase of clinically irrelevant alerts leading to alert fatigue, and the lack of supplementary information. By incorporating provider preferences, customizing alerts to the context of the visit, and offering additional clinical data, providers felt that alerts would be less likely to be overridden providing more effective and efficient care.

Analysis of Content Coverage for Informed Consent Concepts

Frank J. Manion, MS[1], Elizabeth R. Eisenhauer, RN, MLS[2], Alla Karnovsky, PhD[3], Yongqun He, PhD[4], Yu Lin, PhD[4], Marcelline R. Harris, PhD, RN[2]

Introduction

Knowledge embedded within informed consent for research is of increasing interest in light of efforts to establish large strategic and distributed research networks. Information models and terminology systems can be used to model such knowledge within a domain; well-formed models can inform model driven approaches to developing systems and software that incorporate the model-derived functional and semantic interoperability specifications and ultimately execute on specific implementation platforms. The informed consent domain however lacks comprehensive models of the necessary interactions of information and attributes arising from the informed consent processes and artifacts. Ideally, coherent, canonically-linked formal models of the informed consent for the research domain, incorporating information models and terminology, would allow for improvements in data sharing, secondary use of data, and facilitate IRB review in multiple sharing environments such as consortium and research networks.

Objectives

We report on the first phase of a larger project focused on modeling this domain. In this study we evaluated terms and concepts derived from three different informed consent templates, each representing a different perspective: biomedical clinical research, health and behavior science research, and biorepositories. Specific aims were to 1) identify unique concepts across three IRB templates; 2) map concepts to Concept Unique Identifiers (CUIs) within the Unified Medical Language System (UMLS), and 3) examine content coverage across 2 information models (BRIDG, HL7 RIM) and 4 terminology systems, NCI thesaurus (NCIt), Consumer Health Vocabulary (CHV), Ontology of Biomedical Investigation (OBI), and the University of California San Diego (UCSD) informed consent permission ontology.

Methods

Manual review and annotation of informed consent templates from two University of Michigan IRBs was performed covering 1) biomedical clinical research, 2) health and behavior science research, and 3) the prospective biobanking of DNA. Terms were collected from the 6 terminologies and information models named above. Using the UMLS Terminology Services (UTS) Metathesaurus Browser, each term was entered into the manually reviewed to identify a CUI, terms and definitions consistent with the meaning of the term in the consent template. BioPortal was used to search for OBI and UCSD terms.

Results

324 terms were initially identified from the three templates. Removal of synonyms and duplicates resulted in 296 unique terms; 11 could not be mapped to CUIs. Of the remaining 285 terms, the NCIt provided the most extensive coverage (200 terms), and the UCSD consent permission ontology the least coverage (12 terms).

Discussion & Conclusion

We have identified a set of concepts, CUIs, definitions and preferred terms from key source systems that are needed to more fully model the domain of informed consent. Next steps include an analysis of the binding of the relevant aspects of the information models with the terminology systems, and validation using informed consent templates from other organizations.

Systems Informatics and Information Modeling in Healthcare

Abstract

Due to the importance of systems thinking in healthcare and the usefulness of information modeling in clinical informatics, best practices of systems design and management (SDM) and its application to information modeling were compiled and considered. A resulting set of best practices was arrived at for a systems approach to informatics and information modeling.

Introduction

Systems design and management (SDM) has been increasingly recognized as an important capability in healthcare[1-5], which can be regarded as a system of many intricately interacting parts. In this work, best practices of SDM and their application to information modeling were considered by the Information Modeling Center of Excellence at Partners HealthCare System[6]. A resulting set of high-level best practices was arrived at for a systems approach to clinical informatics and information modeling.

Methods

As input knowledge for consideration, several key references on SDM were reviewed[1-5]. The input of members with systems thinking or engineering background was also obtained and reviewed. The best practices were extracted and organized to arrive at recommendations for systems informatics methods.

Results

Many widely known best practices were confirmed, including well-known methods for information system design and implementation. Other important, less frequently discussed practices included iterative problem definition, adopting rigorous engineering methodology, dependency management, challenging previous assumptions, and global optimization. For example, relaxing an assumption of only simple relationships in a patient's family history results in a model that was structured to allow for a more complete and rigorous pedigree for better decision support.

Conclusion

In order to address the increasing complexity of informatics needs in healthcare, a systems approach provides access to solutions of greater comprehensiveness and optimality.

Comparing Accuracy, Efficiency, and User satisfaction of Two EMR interfaces

David T. Marc, MS[1], Charat Thongprayoon, MD[2], Andrew Harrison, BS[2], John C. O'Horo, MD, MPH[2], Ronaldo A. Sevilla Berrios, MD[2], K. Harder, PhD[3], Brian Pickering[2], MD, Vitaly Herasevich, MD, PhD[2]

[1]Institute for Health Informatics, University of Minnesota, Minneapolis, MN; [2]Multidisciplinary Epidemiology and Translational Research in Intensive Care (METRIC), Mayo Clinic, Rochester, MN; [3]Center for Design in Health, University of Minnesota, Minneapolis, MN

Abstract The purpose of this study is to compare the accuracy, efficiency, and cognitive load of completing various clinical tasks in a critical care setting and overall user satisfaction between two patient information displays: AWARE (Ambient Warning and Response Evaluation) and a traditional EMR. When compared to a traditional EMR display, the AWARE interface lead to lower cognitive task load and higher efficiency of task completion.

Introduction EMR platforms continue to proliferate, often with insufficient attention to aspects important to ensure that meaningful information is conveyed to users. A novel patient information display, AWARE, was designed to provide an easy-to-use and easy-to-learn electronic patient information display that presents meaningful information to clinicians to improve their decision-making and reduce errors. AWARE extracts and combines textual and graphical elements to convey specific clinical patient information on one screen in contrast to multiple pages in a traditional EMR. The goal of this study is to determine if the AWARE interface leads to greater accuracy and efficiency of completing various clinical tasks when compared to a traditional EMR.

Methods A randomized crossover design was used to assess the performance of 5 research fellows (all of whom trained outside the US) without extensive experience using the AWARE patient information display or the traditional EMR display. The subjects completed global and localized tasks. Global tasks required subjects to answer questions pertaining to all patients on a specific patient unit and were completed once per electronic display (AWARE or traditional EMR). Localized tasks required subjects to answer clinical questions about three randomly selected patient cases for each display. The National Aeronautics and Space Association Task Load Index (NASA-TLX) was used to measure task workload on a 1-100 dimensionless scale, where higher numbers correspond to greater cognitive demand. An electronic timer was used to measure the time subjects needed to perform each task. Task accuracy was determined based on the correctness of the subject's responses to each task. At the conclusion of the experiment, each subject completed a user satisfaction survey.

Results When comparing the results of the NASA-TLX for the two systems, the traditional EMR (mean: 72.1, SEM: 6.8) had significantly higher weighted scores than the AWARE interface (mean: 27.8, SEM: 6.2, p=0.001). The AWARE interface took significantly less time to complete tasks when compared to the traditional EMR for both the global tasks (mean: 65 sec vs 0.257 sec, p<0.05) and localized tasks (mean: 37 sec. vs 59 sec., p<0.05). There was not a difference in the accuracy of the clinical tasks completed between the two interfaces. Additionally, subjects reported that AWARE was easier to use, lead to greater productivity, and was an overall improvement over the functionality of the traditional EMR display.

Conclusions The AWARE patient information display led to lower cognitive load and greater efficiency when completing various clinical tasks and improved user satisfaction than a traditional EMR in an experimental setting.

A New Visual Navigation System for Exploring Biomedical Patents

Christopher Markson, MS, Songhua Xu, PhD
Department of Information Systems, College of Computing Sciences,
New Jersey Institute of Technology, Newark, NJ 07102, USA

Abstract

This research develops a new visual navigation system for exploring key technologies and trends along with their temporally evolving relationships exhibited by biomedical patent literature. The proposed system is implemented as a web-based graphical browsing environment (http://web.njit.edu/~crm23/AMIA) through which users can examine key technologies together with their dynamics and inter-relationships as revealed by the patent literature.

Introduction

US Patent and Trademark Office (USPTO) biomedical patents are valuable intellectual assets of the community. In particular, the *Claims* section of a patent document provides rich information disclosing technological advancement[1]. We therefore focus on this central element to algorithmically discover and graphically present valuable technologies and their trends in biomedicine.

Our Method: Data Collection, Manipulation, and Visualization

Four years of Google Bulk Patent[2] data are used in this work to allow for a temporal analysis of biomedical patents. The aim is to computationally detect and visually reveal the dynamic relationships between technological concepts and the technological advancements relevant to a user's interest. For each patent document, its claims section is parsed for *keywords* and *salience weights* using the RAKE algorithm[3]. In total, 88,493 patents are processed and 2,501,012 keywords are extracted. To identify frequent co-occurrences of keywords among all patents, the Apriori algorithm is used to extract frequent keyword item sets[4]. For each graph representation, nodes represent frequent keywords occurring in the claim data. Edges represent a collection of patents that share certain relationships between their keywords. The Sigma.js platform was chosen as the underlying visualization platform due to its scalability[5]. We also modify the platform to enable the removal of keywords from the displayed graph to adjust the amount of information presented.

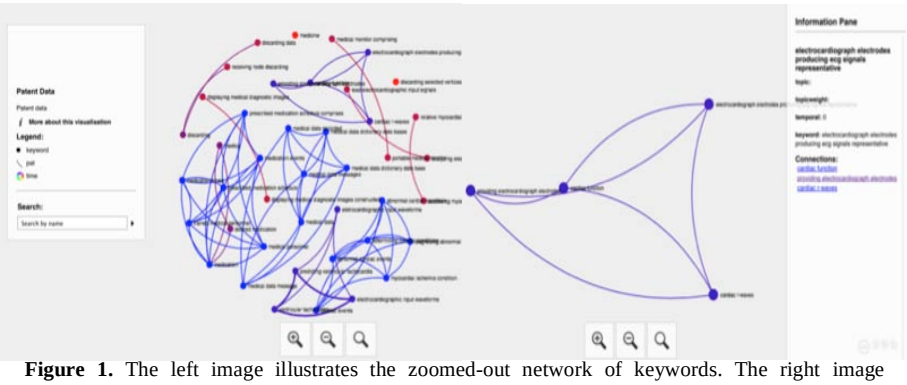

Figure 1. The left image illustrates the zoomed-out network of keywords. The right image illustrates a close-up on a particular set of connected keywords.

Conclusion

This work presents a new visual navigation system built on an open-source platform for identifying key technological concepts in biomedical patent claims as well as these concepts' dynamic relationships and development trends. The visualization platform introduced in this study renders the results of patent claims analysis through visually informing graphs.

From computer scientists to research practitioners: lessons learned when implementing use of mobile devices in a cancer research setting

Stephanie L. Martch, MS, RD[1], Karen Basen-Engquist, PhD, MPH[1], Wendy Demark-Wahnefried, PhD, RD[2], Alexander V. Prokhorov, MD, PhD[1], Kevin Patrick, MD, MS[3], Eileen H. Shinn, PhD[1], Emilia Farcas, PhD[3], Chaitan Baru, PhD[3], Ingolf Krueger, PhD[3], Kai Lin, PhD[3], Phil Rios[3], Yan Yan[3],Viswanath Nandigam[3], Susan K. Peterson, PhD, MPH[1]

[1]MD Anderson Cancer Center, Houston, TX; [2]University of Alabama at Birmingham, Birmingham, Alabama; [3]The University of California, San Diego, La Jolla, CA

Mobile health and internet-based technologies can provide effective tools for managing the healthcare of cancer patients, although a dearth of research exists to provide evidence of clinical impact.[1] CYCORE (CYberinfrastructure for COmparative effectiveness REsearch) is a software-based prototype of a user-friendly CyberInfrastructure (CI) designed to support collection and analyses of cancer prevention and treatment data from multiple domains using home-based mobile sensors. A collaborative effort between CYCORE's computer scientists and engineers at the University of California, San Diego (UCSD), and behavioral scientists from two cancer centers (MD Anderson [MDACC], Houston, Texas; and University of Alabama at Birmingham) enabled requirements gathering from over 100 cancer center stakeholders. This work informed the prototype design to address four real-world use cases that assessed (1) physical functioning in colorectal cancer patients, (2) dehydration risk in head and neck cancer (HNC) patients undergoing radiation therapy (RT), (3) adherence to swallowing exercises in HNC patients undergoing RT, and (4) tobacco use in cancer survivors who completed an in-house tobacco treatment program. Devices for the four use cases were, respectively: (1) a heart rate monitor, two accelerometers, and a blood pressure (BP) and global positioning system (GPS) device; (2) a BP device, two accelerometers, and a weight scale; (3) a smartphone-based video application (app); and (4) a carbon monoxide monitor and the smartphone-based video app. All device suites included a miniature computer base station for home use to handle both wireless and wired data acquisition and CI transmission, and a smartphone that featured in-house-developed apps to record/transmit self-reported data and applicable videos. The UCSD group encoded devices and modes for data collection, transmission and storage; as well as CI integration and display. The research dissemination group at MDACC developed protocols for conducting four use-case-related feasibility trials that included participant user guides designed to minimize concerns about device functionality[2]; staff guides to set up, maintain, and inventory devices and to track and troubleshoot device problems; and protocols for addressing mobile device service provider issues that arose. This poster will present several lessons learned by the research dissemination group during incorporation of mobile devices into a cancer research project including (1) the need for research staff to become site technology experts by delving into the manufacturers' usage manuals to create staff troubleshooting guides as well as simple need-to-know participant device usage booklets, (2) how to "tame" the smartphone, so that its extensive features do not interfere with research goals, and (3) considerations for the simultaneous use of multiple devices that collect continuous data.

Point of Care Intake Tool and Clinical Decision Support to Achieve Meaningful Use

Maryanne E. Mathiowetz, M.P.H., Jennifer L. Horn, M.D., Samanthie I. Epps, M.B.A., Paul J. Johnsen, B.S., Pedro J. Caraballo, M.D.
Mayo Clinic, Rochester, Minnesota

Abstract
Capture of discrete data during routine clinical practice is critical for the Meaningful Use of the electronic health record (EHR). We developed a smart form integrated in the EHR. After implementation, structured data capture for specific MU measures improved from 0% to >95% without affecting workflow efficiency. We concluded that standard EHR functionality can be enhanced to support an efficient workflow and improve standardization and reporting.

Introduction
The Meaningful Use (MU) program provides incentive payments to ambulatory care facilities based on specific criteria. Capture of discrete data is a critical MU requirement. Most of these data are captured during routine clinical practice at our institution, but the existing documentation was poorly standardized, available only in a textual format, outside of the certified EHR, or absent. Our aim was to use certified EHR functionality to develop a smart form for intake documentation that would comply with MU without negatively impacting clinical practice.

Methods
Our institution has GE Centricity Enterprise as the main component of the EHR. We used standard functionality including FlowForm, rule engine and scripting to customize an intake smart form to be used by clinical assistants and nurses to gather and document information needed for the outpatient visit. The main requirements for the smart form and the functionality we used to achieve those requirements were: 1) Support intake standardization (best practice) with synchronous decision support to prompt documentation at the appropriate intervals and visit types. 2) Maintain efficiency of the intake process while changing what is documented and how by a) eliminating redundant documentation, with data sharing across EHR components, b) providing visual cues (color, icons, etc.) to focus documentation where needed and ensure completeness, c) incorporating pick lists, check boxes, radio buttons, and automated calculations for ease of charting in discrete fields, and d) facilitating navigation within and between the EHR and other electronic tools including direct access to printable resource materials for the patient. 3) Connect the smart form and the provider's note to transfer the discrete intake data to the designated note sections in the appropriate format for the provider. 4) The development strategy also required that the smart form be scalable to support future phases of MU as well as other external reporting requirements and practice changes.

Results
The intake smart form was implemented in six primary care areas with approximately 300 clinical assistants and nurses and is used for approximately 3500 to 4000 visits per week. There were three MU categories for which a complete set of elemental data was not available for reporting from the certified EMR in the baseline workflow (0%): Adult Weight Screening and Follow-up, Tobacco Use and Cessation Intervention, Weight Assessment and Nutrition/Exercise Follow-up for Children and Adolescents). Following the implementation, our institution's MU Reporting Team found that the compliance rate for the measures in these categories did increase to above 95%. No difference was found in the duration of the intake process when comparing a pre-implementation baseline time period with multiple post-implementation time periods. Following the original implementation, additions and enhancements have been made in support of new external reporting requirements and practice changes.

Conclusion
Creative documentation process redesign based on existing functionality of a certified EMR can produce new tools that support MU and other reporting requirements, as well as help to standardize best practice and support efficient workflow. Particularly notable with this implementation was the lack of impact on the providers in the clinical practice, as demonstrated by no increase in pre-visit intake time and no decrease in the availability of intake documentation in the provider's note.

Using REDCap to Evaluate Clinical Decision Support Alert Appropriateness

Allison B. McCoy, PhD[1,2], Eric J. Thomas, MD, MPH[3], Marie Krousel-Wood, MD, MSPH[1,2], Dean F. Sittig, PhD[3]
[1]Tulane University, New Orleans, LA; [2]Ochsner Health System, New Orleans, LA; [3]The University of Texas Health Science Center at Houston, Houston, TX

Abstract

Effectively evaluating the appropriateness of clinical decision support (CDS) alerts and responses is critical to improving patient safety through health information technology. We describe the use of REDCap to create a data collection instrument for evaluating the appropriateness of CDS alerts and responses. While the tool is effective, further enhancements to REDCap would improve the process for future evaluations.

Introduction

Computerized alerts that warn clinicians about drug interactions or provide dosing guidance are commonly implemented forms of clinical decision support (CDS) to improve patient safety. Alert overrides can hinder provider effectiveness and result in adverse patient outcomes. Detailed evaluation of the appropriateness of alerts and clinician responses is necessary; however, few have described the processes for performing these evaluations.

Methods

Based on a previously described evaluation framework,[1] we developed an assessment tool using REDCap (Research Electronic Data Capture), a secure, web-based application designed to support data capture for research studies.[2] The tool was designed to facilitate reviews by clinicians in determining the appropriateness of CDS alerts and responses.

Results

We created a single data collection instrument within REDCap for reviews of CDS alert and response appropriateness. The instrument consists of data fields in two sections: alert log data to assist clinicians during reviews and questions for the clinicians to answer while conducting the reviews. We extracted log data from the electronic health record and imported it into REDCap to populate these fields prior to clinician reviews. For the second section, clinician reviewers indicated whether the alert and response were appropriate, why the alert was inappropriate (if applicable), and what response(s) would have been appropriate. Each alert was reviewed by multiple clinicians to allow assessment of inter-rater agreement. Use of REDCap was advantageous in that it allowed quick, easy development of a HIPAA-compliant data collection tool that is simple for clinicians to use. However, although REDCap allowed importing of data and multiple reviews of a single record (i.e., dual data entry), the two could not be used together. As such, we created data access groups for each reviewer, assigned each alert a separate, unique identifier for each reviewer, then assessed agreement and merged responses outside of the REDCap system.

Conclusion

We successfully used REDCap to create a data collection instrument to facilitate evaluation of CDS alert and response appropriateness through chart review by clinicians. Further enhancements to REDCap, such as the ability to import data with dual data entry, would improve the process for future evaluations.

Identifying Strategies to Promote Adoption of a Web-based Patient-Centered Communication Tool by Providers in the Acute Care Setting

Kelly McNally, [1] Diana Stade, [1] Patricia C. Dykes, RN, PhD,[1,2] David W. Bates, MSc,[1,2] and Anuj K Dalal, MD[1]

[1]Brigham and Women's Hospital, Boston, MA, [2]Harvard Medical School, Boston, MA

Abstract: *Web-based tools may improve patient-centered communication but require provider acceptance to realize its full potential. We designed a web-based communication tool to manage electronic conversations among patients and providers in the acute care setting. We conducted focus groups to explore potential uses, perceived impact on workflow, and provider concerns regarding the tool. We identified potential barriers and developed strategies to optimize adoption of the web-based communication tool.*

Introduction: Promoting patient-centered communication may favorably impact patient safety, quality of care, outcomes, and healthcare costs.[1] Web-based communication tools such as microblogs have the potential of improving patient-centered communication among patients and providers, but have not been systematically adopted in complex hospital settings. Although patients are eager to use such tools to communicate with providers, providers have expressed resistance in using them.[2] The purpose of this study is to identify barriers to implementing a web-based communication tool and establish strategies to maximize adoption by providers in the acute care setting.

Method: We conducted 3 focus groups, consisting of 4 to 6 providers (attending physicians, physician assistants, and housestaff) at Brigham and Women's Hospital. During each session we presented the intended use of and discussed provider concerns with regard to effectively using the web-based communication tool. We debriefed following each focus group to analyze and discuss the implications of our findings. We then identified optimal strategies for implementation and training.

Results: We identified two types of barriers that could impede adoption. *Clinical workflow barriers* consisted of ensuring easy access to the web-based communication tool (which varied by provider type), and integrating the tool into clinicians' demanding inpatient work schedules. *Provider "emotional" barriers* consisted of concerns regarding notifications of new messages, fear of providing poor quality patient care (e.g., by virtue of spending less time with patients at the bedside), and malpractice concerns pertaining to communication between patients and providers.

Conclusions: We developed strategies to promote adoption of our web-based communication tool based on the clinical workflow and emotional barriers identified in focus groups. Strategies to address *workflow barriers* include identifying key clinical applications used by different providers, ensuring reliable use of those applications, providing links to the web-based communication tool from those applications, and establishing a specific time within current work schedules to review electronic conversations. Strategies to manage *emotional barriers* are as follows*:* providing several user-configurable options for message notification (e.g., email vs. mobile "app" push-notification) to mitigate perception of alert fatigue; framing use of the tool as a means to supplement patient care activities rather than replace existing practices to address patient care quality concerns; and finally, educating providers regarding appropriate messaging etiquette when communicating with patients and other providers and indicating that hospital administration supports use of the tool to mitigate legal concerns related to posting messages on the web-based communication tool.

Introduction
The American College of Emergency Physicians recommends the use of Wells' Score for Pulmonary Embolism (PE) and D-dimer as objective risk-stratification of patients with suspected PE prior to ordering computed tomography pulmonary angiogram (CTPA). Implementation of these recommendations by use of algorithmic clinical decision-support (CDS) incorporated into computerized provider order entry (CPOE) has been demonstrated with mixed results. Our objective was to evaluate the acceptability of such CDS at our institution, with the hypothesis this intervention would increase positive CTPA yield for PE.

Methods:
This study was performed at a Level 1 academic emergency department with an enterprise-wide electronic health record. A CDS algorithm for guideline-compliant diagnosis of PE using Wells' Score and D-dimer was integrated into CPOE. A baseline CTPA positivity rate of 8.0% for acute PE was determined from the most recent 250 studies prior to the intervention going live. The evaluation period following CDS implementation was from March 1, 2014 until July 10, 2014. Upon placing a CTPA order, the CDS flow chart is reflected in Figure 1. Alert #1 prompted clinicians to complete a checklist for objective risk-stratification by Wells' Score. Alert #2 prompted clinicians with recommendations to discontinue the CTPA order if the patient were low- or intermediate-risk, and the D-dimer result was <0.4 μg/mL. Data were collected retrospectively on all patients who had a CTPA ordered and charts were abstracted for the presence or absence of D-dimer results, Wells' score documentation, and CTPA result.

Results:
CTPA were ordered on 262 patients during the evaluation period. The flow of these patients through the CDS is summarized in Figure 1. 49 patients had an elevated D-dimer recorded and no prompts were displayed, 3 (6.1%) of whom were diagnosed with acute PE. Alert #1 was shown 213 instances, but acceptability was poor, with only 61 risk-stratification checklists completed. Overall, guideline-compliant care was performed in 69 patients, resulting in 7 (10.1%) positive CTPA. However, the overall positive CTPA yield of our institution's entire CTPA cohort also increased to 13.8% during the observation period.

Discussion
The CDS tool had poor acceptance at our institution, as evidenced by the disproportionate number of CTPA completed without objective risk-stratification. Due to the limited sample of completed CDS checklists, no valid conclusions may be drawn regarding the effectiveness of the CDS. Causative factors for the increased yield of CTPA during the observation period are unclear. A Hawthorne effect associated with CDS implementation cannot be excluded.

Assessment of the Quality of Computerized Physician Order Entry (CPOE)-Related Medication Error Reports in a Large Medication Error Database

Amato MG, PharmD, MPH[1,2]; Seger AC, PharmD[1,]; Wright A, PhD[1,3]; Koppel R, PhD[4]; Rashidee AH, MBBS, MS[5]; Elson RB, MD[6], MS; Whitney, DL, BS[7]; Thach TT, MPH[1]; Bates DW, MD, MSc[1,3,8]; Schiff GD, MD[1,3]

[1] Brigham and Women's Hospital Division of General Medicine and Primary Care, Boston, MA, USA, [2] MCPHS University, Boston, MA, USA, [3] Harvard School of Medicine, Boston, MA, USA, [4] University of Pennsylvania, Philadelphia, PA, USA, [5] Quantros, Inc., CA, USA, [6] MetroHealth Center for HealthCare Research and Policy, Cleveland, OH, USA, [7] Baylor College of Medicine, Houston, TX, USA[8] Harvard School of Public Health, Boston, MA, USA

Abstract: *Improved awareness and monitoring of medication errors related to CPOE can help institutions implement effective prevention strategies. The objective of this study was to assess the quality of narrative reports of CPOE-related errors in the MEDMARX database and identify qualities of useful error reports.*

Background: Reports of adverse drug events and medication errors are more useful if they include well-written narrative reports in addition to structured data.[1, 2] Monitoring of medication errors related to CPOE can help institutions identify potential causes and implement adequate error prevention strategies to improve patient safety.

Methods: We assessed quality of error report narrative descriptions included in the MEDMARX reporting system from 2003-2010 that were listed as being related to CPOE. MEDMARX is a national reporting program developed by the United States Pharmacopeia (now administered by Quantros) containing >1.2 million reports from over 860 facilities. For each error narrative, we assessed "what" happened, "why", and how the error might be prevented, and ranked overall quality of the narrative report (1 = no information, 2 = poor information, 3 = some information, 4 = adequately described, and 5 = error well described). We also ranked how easily the cause of the error could be determined from the report (1 = no information, 2 = poor information, 3 = some information, 4 = adequately described, and 5 = cause well described), assessed whether the report described the specific involvement of CPOE, whether the narrative report was consistent with structured data included in the report and whether the narrative report improved overall understanding of the error when added to structured data.

Results: Of 63,040 error reports classified as related to CPOE during 2003-2010, we reviewed a stratified random sample of 10,060 (16%). Quality of the error reports was ranked as well-described in 1336 (13.3%) and adequate in 3312(32.9%). 2871(28.5%) had some information, 2265 (22.5%) were poor and 274(2.7%) had no information (example: only stating "CPOE error"). Cause of the error was rated adequate or well described in 20%, however 51.6% included no information to assess error cause. CPOE involvement was well described in 13.6%, mentioned with some details in 20.4%, lacking details in 13.2%, and implied or not mentioned in 49.8%. In a random sample of 100 reports coded by two investigators, inter-rater reliability using linear weighted kappa was good for quality of the error report (kappa 0.604), cause of the error (kappa 0.692), and CPOE involvement (kappa 0.606). A temporal trend was seen with an initial improvement in quality scores after the first two years, which leveled off for the remaining five years studied. Narrative reports were somewhat or clearly consistent with structured data in 89.1%. The narrative improved overall understanding of the error in 97%. The highest rated quality reports included clear descriptions of what happened and suggested potential error causes and contributing factors.

Conclusion: Narrative reports improved understanding of what happened in this large database of CPOE-related medication error reports, however over half of the reports did not include enough detail to assess causes and suggest prevention strategies. It is important for healthcare systems to focus on improving the quality of medication error reports in order to learn more about causes and implement health information technology strategies to prevent subsequent errors.

Application of Pediatric Dosing Rules Across a Diverse Health Care System

Paul E. Milligan PharmD[a], Nicholas B. Hampton PharmD[a], Chandana Anigolu BE[a], Kevin Heard BS[a], Melissa Heigham PharmD[a], Paul Hmiel MD[b], Keith F. Woeltje MD, PhD[a,b]
[a]BJC HealthCare, Saint Louis, MO [b]Washington University School of Medicine, St. Louis, MO

Abstract
Over time, specific pediatric dosing rules have been developed, tested, refined and applied to all patients at St. Louis Children's Hospital (SLCH), the academic pediatric hospital of the BJC HealthCare System. However, 20% of all pediatric inpatient hospital visits to BJC HealthCare were to our community hospitals in 2012. Pediatric dosing rules have not been applied consistently outside SLCH, primarily due to diverse formularies and different clinical information systems. In 2013, we built pediatric dosing rules for drugs judged to have the highest potential for adverse events based on historical data and an expert panel. These rules will alert pharmacists system-wide, as well as provide evidence-based instructions on how to communicate the proper dose to the physician.

Background
BJC HealthCare is a health system based in St. Louis Missouri comprised of one pediatric, two academic and eight community hospitals. Twenty percent of BJC HealthCare's 2012 pediatric hospital admissions (excluding standard births) were at the community hospitals. St. Louis Children's Hospital, the academic pediatric hospital, developed, tested, and refined specific pediatric dosing rules. Until recently, these rules have not been applied consistently across our system. The primary reasons for this inconsistency are the diverse formularies and different clinical information systems. Therefore, a team set out to develop and apply a starter set of pediatric dosing rules for drugs judged to have the highest potential for adverse events to children at all of our hospitals.

Methods
The BJC HealthCare Clinical Decision Support (CDS) Collaborative, a system-wide CDS steering committee, commissioned an effort to implement a starter set of pediatric dosing rules at all hospitals. To initiate this effort, system-wide inpatient pediatric medication order data were collected from the Pharmacy Expert System (PES), a BJC HealthCare developed enterprise CDS system[1]. The top 50 prescribed drugs were then reviewed by a SLCH physician and 3 pharmacists to identify medications with the greatest potential for adverse events. St. Louis Children's Hospital previously went through a similar exercise to target medications, and developed, tested, and refined dosing rules in their custom Dose Range Auditing and Checking Overseer (DRACO) application[2].
After identifying a set of 19 high-risk drugs, dosing rules were developed in PES for these drugs to act as a safety-net for the entire system. PES continually screens the electronic medical record and when rules are violated, an alert is displayed on a webpage for the local clinical pharmacist to review. As these rules will be triggered rarely, often to non-pediatric specialty pharmacists, the alert will include evidence-based instructions on how to communicate the proper dose to the physician.

Results
The high-risk drugs identified are listed below: ampicillin, acetaminophen, caffeine, cefazolin, cefotaxime, ceftriaxone, diphenhydramine, fentanyl, gentamicin, heparin, hydrocodone with acetaminophen, ibuprofen, midazolam, morphine, potassium chloride, ondansetron, oxycodone, oxycodone with acetaminophen, and phenobarbital.

Discussion and Conclusion
We identified an at-risk population of patients, then systematically identified, developed, and applied a set of CDS rules to protect them. We then gave the pharmacists tools to help communicate dosing rules to the prescriber. Until real-time applied dosing rules upon order entry become more sophisticated, asynchronous CDS dosing rules are an effective safety net to protect patients consistently from adverse events.

Author's Note: Alerts per screened order data is not currently available, but we plan to present this data on the poster.

Identifying eHealth literacy demands of health information seeking tasks

Jelena Mirkovic, PhD[1], Maria Sims, BS[2], David R. Kaufman, PhD[2]
[1]Oslo University Hospital, Oslo, Norway; [2] Arizona State University, Scottsdale, AZ

Abstract

To be able to effectively engage eHealth systems the individuals must possess a set of skills and knowledge referred to also as eHealth literacy. The presented work analyzes participants' barriers while performing health information seeking tasks on MedlinePlus. The goal is to classify task demands in terms of different literacy types and diagnose cognitive operations at varying levels of complexity. The objective is to contribute to design strategies that serve to reduce complexity for fuller consumer participation.

Introduction

eHealth systems play an increasingly important role in engaging patients as productive participants in health management and decision making process. eHealth literacy refers to a set of skills and knowledge that are required for an individual to effectively use eHealth systems. Chan and Kaufman developed a methodological framework to classify tasks demands and user performance according to different eHealth literacy types and cognitive complexity levels (e.g., analysis, evaluating, comprehending)[1]. The goal of this study is to identify and classify potential barriers in health information seeking tasks with greater precision along the dimensions specified by the framework. The ultimate objective is to provide resources to individuals of lower literacy on problems of greater complexity.

Method

Fifteen participants were recruited from a community center associated with Columbia University to perform a set of information retrieval tasks in view to solve hypothetical health problems using MedlinePlus. Participants ranged in age between 30 and 65, with most participants in their 50s and of varying levels of literacy. In this paper, we report the results of a study in which users are tasked to find information related: (1) to management of high blood pressure, and (2) causes, signs, treatment of ADHD. The participants were video-recorded and analyzed using Morae™ usability and video-analytic software. This project was approved by the Columbia University IRB.

Results

Each task presented unique configurations of complexity that presented challenges for users as measured by errors, requests for help and the need for experimenter prompts. Barriers observed during task completion were noted and the framework coding was then applied to perform classification based on literacy type and complexity level (Table 1). The analysis showed that the majority of encountered barriers were associated with participants' lack of information literacy and health literacy. Participants struggled with recognizing and understanding needed information and evaluating and applying the health-related information. Additionally, a substantial number of barriers were classified as computer literacy and numeracy issues.

Table 1. Number of barriers participant encountered mapped to literacy types

	Computer literacy	Information literacy	Traditional literacy	Health literacy
Task 1	17	30	19	15
Task 2	8	29	7	21
Both tasks	**25**	**59**	**26**	**36**

Conclusion

The study revealed barriers that health consumers encounter when using online eHealth tools according to type of eHealth literacy and the specific information-seeking demands of the task. The results can be used to inform improvement and development of eHealth tools for health consumers that vary in terms of their eHealth literacy.

Title: Methods for Patient Matching in Patient-Centered Outcomes Research

Authors: Adil Moiduddin, Prashila Dullabh, Michael Latterner, Samantha Zenlea, Michael Davern

Theme: Clinical Research Informatics

Introduction and Purpose. This paper describes opportunities for and barriers to linking patient-level data across different health data sources, a process called "patient matching." Effective patient matching creates a more complete patient record, which can improve individual-level clinical care and care coordination. It can also enhance patient-centered outcomes research (PCOR), including public health and quality-based initiatives, by uniting disparate data sources (e.g., claims, pharmacy, clinical, and disease registry data) for analysis. In assessing the necessary data infrastructure to support patient matching, we sought to answer the following questions: 1) What types of datasets need to be linked to enable PCOR? 2) What is the general process used for linking datasets and what challenges arise? 3) How could existing processes and technologies be improved? ; 4) What innovations or strategies would help achieve these improvements?

Methods. This qualitative study included; 1) an environmental scan and literature review to identify key resources; and 2) Semi-structured telephone interviews with 9 experts with relevant experience with patient matching, such as expertise in creating standards and strategies for matching individual records from disparate data sources; linking data to research the care continuum and care coordination; or background in public health.

Principal Findings

We identified the processes behind patient matching and the associated technical considerations, such as matching methods and data governance considerations, as well as the challenges faced by stakeholders in accessing the data needed for effective matching. Experts noted challenges stemming from:

- Need for consensus on core patient attributes to capture for accurate matching;
- Need for adequate standards for data quality and methods for understanding the implications of variable data quality;
- Significant error rates associated with current methods of matching;
- Pros/cons of algorithms employed for data matching;
- Restrictions on use of patient attributes in data for research;
- Resource requirements to conduct patient matching; and
- A business culture that does not facilitate open sharing of data-matching strategies across organizations

Conclusions. Large scale patient matching among disparate data sources requires advanced technical and statistical solutions, as well as the management of complex data governance issues, including patient safety and privacy and informed consent. In order to realize the potential of data matching to support PCOR, these complex issues require leadership. Here, we describe areas in which ongoing or new initiatives can help address important obstacles to patient matching through improvements in data standards, policies, and infrastructure.

A study of synonym extraction from clinical texts using semantic vector models

Sungrim Moon, Ph.D.[1], Trevor Cohen, MBChB, Ph.D.[1,2], Hua Xu Ph.D.[1]
[1]School of Biomedical Informatics, The University of Texas Health Science Center at Houston, Houston, TX, USA; [2]National Center for Cognitive Informatics and Decision Making in Healthcare, Houston, TX, USA

Introduction: Synonyms have different lexical forms but share the same sematic meanings. Automatically extracting synonyms has been researched to capture the different levels of semantic relatedness between two terms. As an informational retrieval approach, the Vector Symbolic Architectures (VSAs) has been utilized with distributional hypothesis, which is terms in the same contexts tend to have similar meaning. To overcome computation burden and poor scalability of Latent Semantic Indexing (LSI), Random Indexing[1] (RI) was successfully utilized. Moreover, RI encoding additional information shows the good performance to identify general English TOEFL synonym evaluation. This additional information includes relative orientation (Random Direction, RD) or the relative term position with order information (Random Permutation, RP) from a given term. Another variance, Term-based Reflective Random Index (TRRI) uses iterative vector generation to identify latent relationship among terms.

Methods: We investigated automatic synonym extraction from clinical documents using various distributional semantic vector models. Our clinical corpus consists of 189,099 clinical notes spanning two years extracted from a local clinical data warehouse. The corpus contains unique 82,655 unique terms with a minimum frequency of five or more occurrences, after pre-processing with Lucene and the exclusion of terms that contain non-alphabet characters. In this experiment, we used 490 unigram synonyms, which were automatically extracted from the UMLS/SNOMED-CT, and manually validated by one expert. We applied RI, RP, and TRRI to find the nearest neighbors of the cue terms in this gold standard set. The dimensionalities of the vectors used were 200, 500, 1000, and 1500 with real vector representation. For RD and RP, five different window sizes (window radius of 1, 2, 3, 4, and 5) were tested. For evaluation, we extracted the ten nearest neighboring terms from the model after post-processing (as per Henriksson's method[2]) to eliminate poor suggestions, and then calculated recall at k=10.

Results: Among 48 different models with different dimensions, window sizes, and RI variants, the best recall was 16.73 (1000 dimension, w=3, and RD). For all dimensions, RD models present the best performance with three windows as surrounding words (3 + the given word + 3). With respect to window size, window size of three shows the best recalls for all RD and RP models. All RI variants (RD, RP and TRRI) show better performance than the basic RI model. Higher dimensionalities (>= 1000 in our experience) tend to have better performance. The following Table shows the recall across different parameter settings.

Table. Recalls depending on dimensions, window sides, and variants of RI

	Dimension= 1000				Dimension= 1500			
	RD	RP	RI	TRRI	RD	RP	RI	TRRI
Window size = 1	10.41%	10.41%	1.63%	7.14%	10.20%	10.20%	2.04%	6.94%
Window size = 2	14.90%	12.86%			14.69%	13.27%		
Window size = 3	**16.73%**	13.88%			16.53%	13.67%		
Window size = 4	15.10%	12.86%			16.12%	13.27%		
Window size = 5	15.31%	12.04%			15.71%	12.45%		

* RD: Random Direction, RP: Random Permutation, RI: Random Index, TRRI: Reflective Random Index

Limitations: This study was conducted using a comparatively small English clinical corpus from a single institute with a reference standard that was not exhaustive. Therefore, comparing absolute values of our results to those obtained in Henriksson's study[2] is not meaningful. Nevertheless, our experiments confirm some of their findings (e.g. larger window and higher dimension improve results.) We plan to expand the size of our corpus and reference standard and to combine our models to improve performance in future work.

Conclusion: Variants of RI with different dimensions and window sizes were applied to clinical notes to extract synonyms automatically. RD models considering orientation with a window size of three and 1000 dimension show the best recall. That all of the variants of RIs present better performance then the original implementation of RI, suggests encoding this information is helpful for synonym detection, confirming results of previous studies. In the future, we plan to combine different models to improve performance.

Vocabulary Density Method for Customized Indexing of MEDLINE Journals

James G. Mork, MSc, Dina Demner-Fushman, MD, PhD,
Susan C. Schmidt, MLS, Alan R. Aronson, PhD,
Lister Hill National Center for Biomedical Communications, U.S. National Library of Medicine, National Institutes of Health, DHHS, Bethesda, MD

Abstract

Automated indexing of MEDLINE citations remains a challenging problem due to the growing volume of citations and the over 27,000 MeSH indexing terms that can be assigned to them. This paper presents a corpus-based approach to improving indexing for specific journals. The Vocabulary Density approach takes into account frequencies of indexing terms previously assigned to a journal when recommending indexing terms for a new citation in that journal. After implementing the approach, we saw a 2.69 (4.44%) improvement in Precision.

Introduction

The successes in automatic indexing of MEDLINE® citations using the NLM Medical Text Indexer (MTI)[1] have led to First Line (MTIFL) indexing of several journals. MeSH terms automatically assigned by MTIFL provide the initial indexing to a MEDLINE citation which is then reviewed and completed by an indexer. As we expand the set of journals indexed via MTIFL, we continue seeking improvements to the MTI algorithms. Potential for improvement using journal-specific data was discussed by Tsoumakas et al[2]. To explore whether customizing MTIFL indexing of a journal is worthwhile, we have implemented a simple Vocabulary Density approach for all journals indexed by MTI.

Methods

We used 3,401,111 citations involving 6,606 journals from the 2014 MEDLINE Baseline that have been indexed over the last five years (henceforth referred to as *Corpus*). For each MeSH Heading (MH) used by each journal we captured the number of its occurrences (NOM) and the Number of Articles in the journal (NOA). We then normalized the frequency of each MH in the journal, computing Factor = NOM / NOA. For example, the MH "Swiss 3T3 Cells" occurred four times in the 2,231 articles of the journal "Biochemical Society (Great Britain)" in the *Corpus*. The Factor for this MH is 0.001793 (4 / 2231).

We applied the Vocabulary Density method to journals that had at least 80 citations in the *Corpus* and to MHs introduced at least a year ago. Given the Vocabulary Density information, MTI does not recommend MHs that are not used for the journal and automatically recommends MHs with a Factor > 0.74. For frequently occurring MHs, e.g., Female or Humans, the threshold for automatically recommending is 1 to reduce incorrect recommendations.

Results

On average, only 999 unique MHs of the 27,149 available in 2014 MeSH are used per journal in the 6,606 journals in our *Corpus*. 83.81% of the used MHs are found in 500 or fewer journals and 271 MHs are only found in a single journal (see Figure 1). This selective use of MHs confirms the intuition that taking into account journal-specific data can lead to improvements in MTI recommendations. Furthermore, implementing this simple approach leads to a 2.69 (4.44%) improvement in Precision, 1.36 (2.23%) increase in F_1 score, and a 0.05 (0.08%) increase in Recall.

Conclusion

The significant improvements in Precision without losses in Recall when taking into account the Vocabulary Density information for a journal shows that exploring other potential approaches to using the journal-specific data is worthwhile.

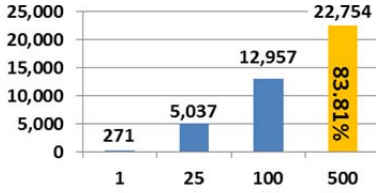

Figure 1. Cumulative MH Usage across Journals

Engaging Patient and Family Stakeholders in Developing Innovative Patient-Centered Care Interventions to Enhance Patient Experience

Conny Morrison,[1] Maureen Fagan, DNP, MHA, FNP-BC,[1] Priscilla Gazarian, PhD, RN,[1,2] Orly Tamir, PhD, MSc, MHA,[1] Jacques Donzé, MD, MSc,[1,3] Patricia Dykes, PhD, RN,[1,3] Diana Stade,[1] David W. Bates, MD, MSc,[1,3] Ronen Rozenblum, PhD, MPH[1,3]
[1]Brigham and Women's Hospital, Boston, MA; [2]Simmons College School of Nursing and Health Studies, Boston, MA; [3]Harvard Medical School, Boston, MA

Abstract: *The use of Patient and Family Advisory Councils (PFACs) are an important step towards patient-centered healthcare, yet the potential contribution of patients and families in developing innovative interventions has been neglected. Thus, we included patients, families and PFACs in the development of interventions aimed at enhancing patient experience. In order to do so, we conducted a focus group and interviews with patients and families to solicit their input on patient-centered care interventions. Our findings describe their contribution to intervention development that truly meets the needs of hospitalized patients and families.*

Introduction: Patient-centered care and patient engagement are part of a shift in healthcare that highlights the value of incorporating patients' needs and perspectives into care.[1] While Patient and Family Advisory Councils (PFACs) have emerged as a key means of involving patients and families in improving quality of care,[2] these stakeholders have been less involved in developing innovative patient-centered interventions. Thus, we engaged Brigham and Women's Hospital PFAC members and hospitalized patients and their families in developing and refining a structured communication model (Patient Satisf*Active*® Model[3]) and a web-based toolkit, interventions designed to improve patient experience in the Medical Intensive Care units (MICU) and Oncology units.

Methods: We selected four patient and family advisors (PFAs) with intensive care and/or Oncology experience to participate in a focus group and individual interviews. Semi-structured focus group and interview guides were developed based on systematic literature reviews and expert input. We interviewed 10 hospitalized patients and families about factors that promote dignity and respect. We also engaged patients and families in testing and refining the tools during 12 additional interviews. Data was analyzed qualitatively for themes. Finally, the patient and family input was reviewed by the MICU/Oncology leadership, to validate feasibility of proposed refinements.

Results: During the focus group, the PFAs shared their hospitalization experiences and gave input on ways to promote dignity and respect within the intervention tools. During the refinement interviews, patient and families tested toolkit usability, providing feedback on the interface and content. The participants' perspective allowed us to identify clinical behaviors and practices, as well as specific toolkit functions, that might enhance patient experience and promote dignity and respect in care; this input was integral to the refinement of the Patient Satisf*Active*® Model and web-based toolkit. In follow-up interviews, the PFAs reported that the focus group meaningfully involved them in the intervention development process. In addition, MICU and Oncology unit leadership recognized the value of these perspectives, and are now working to engage patients in other unit improvement projects.

Conclusions: Our experience validates the value of incorporating the PFAC and patient/family perspective in the development of any truly patient-centered intervention, including health information technologies. Further research is needed to develop valid models of PFAC involvement in healthcare improvement initiatives.

User Preferences Influencing the Design of a Tailored Virtual Patient Educator in a Latina Farm Worker Community

Bijan Morshedi[1], Alexis Chaet[1], Cameron Brown, BA[2], Gloria Arroyo[2], Sara K. Proctor, DW[3], Rupa S. Valdez, PhD[1], Kristen J. Wells, PhD, MPH[2], Laura E. Barnes, PhD[1]
[1]University of Virginia, Charlottesville, VA; [2]San Diego State University, San Diego, CA; [3]Catholic Mobile Medical Services, Dover, FL

Abstract

As use of health information technology increases, the large digital divide between minority groups and the general population runs the risk of widening health disparities. This poster reports on the ongoing design progress for the development of a tailored, low-literacy Virtual Patient Educator (VPE) related to cervical cancer (CC) screening for a community of Latinas in a rural area of central Florida to be delivered in a clinic waiting room through a touch-screen tablet. The incidence of CC among US Hispanics is double that of the general population. These rates are influenced by cultural beliefs, linguistic barriers, socioeconomic status, and low levels of health literacy, which discourage CC screening. This research uses a participatory design approach, which involves integrating the end users of the technology as partners in the design process in order to guide technology development. The research reported in this abstract was supported by the National Cancer Institute and the Office of Research on Women's Health (R21CA167418).

Methodology

Six Latina women were recruited from a faith-based primary care clinic to answer open-ended interview questions on their opinion about the background format of a VPE. The development of this VPE prototype was informed by an initial pilot study consisting of twenty-six interviews within this population and a review focusing on Latino technology usage patterns[1]. Interviews were conducted in Spanish by a native-speaking patient navigator working at the clinic site. Patients were shown three images that only differed in their background color schemes on a touch screen tablet depicting a woman within a home setting to be used for the VPE. Patients were asked a series of questions including their impressions of the furniture in the setting, the appearance of the woman, the room decor, and the wall color. Patients were asked to select their favorite and least favorite settings. Patients were then presented with a panel of button icons. The panel contained five groupings of typical symbols used within American and Latina cultures to depict various button commands: "yes," "no," "next," "help," and "repeat." Patients were asked to state their button preferences for each command. Patients' responses were audio-taped and transcribed verbatim. The San Diego State University and the University of Virginia IRBs approved this study.

Evaluation Results and Conclusions

Background. The majority of participants (n=3) preferred Background 1 (light green) due to the lighter color of the walls, and disliked (n=4) Background 3 (blue) due to the dark or saddening nature of the color scheme. While only one participant liked Background 2 (beige), three patients identified this background as most calming, with two participants identifying background 1 as calming. Overall, patients associated lighter colors with happier, more calming environments. Opinion was divided on the appearance of the furniture; three participants liked the furniture and three participants identified the sofa as uncomfortable. The majority of participants recommended changing the pear painting to another image such as a flower, landscape, or the sun, stating that these images are more comforting and made the setting appear more like a home and less like an office or clinic. Four participants responded that they would feel comfortable being placed within the depicted environment, while two individuals identified the background as "clinic-like," evoking feelings of nervousness.

Buttons. The majority of patients identified the circular-shaped "thumb-up" (n=3) and "thumbs-down" (n=4) symbols as most fitting for the "yes" and "no" buttons, respectively, preference for bold-colored symbols. The colored tailed-arrow was preferred (n=2) for "next" over the white tailed-arrow (n=1) and the arrowhead without the tail (n=0). Bold-colored symbols were preferred for the "next" category as well. There was no one preference identified the question mark button representing "help." Pink was the preferred color option for "repeat" (n=4) over blue. The majority of patients correctly identified each button symbol with the intended button function.

The patient feedback gathered through this study will be used to refine background layout and functionality to design a VPE best tailored to the patients' preferences within this community. Despite the population's receptiveness to a user-centered approach to designing the VPE, not all users may agree on the preferred system attributes. Consequently, we intend to continue to engage community members as we progress with our iterative design process.

An Informatics Framework for Clinical and Translational Research: The Mizzou Approach

Abu S. M. Mosa, MS[1,2], Nate C. Apathy, BSBA[3], Kelly J. Ko, PhD[3], Jerry C. Parker, PhD[1]
[1]Institute for Clinical and Translational Science, University of Missouri; [2]Informatics Institute, University of Missouri, Columbia, MO; [3]Cerner Corporation, Kansas City, MO

Abstract
One of the main challenges in clinical and translational research is providing secure access to clinical data and tools. In this poster, we will demonstrate a workable and secure clinical research informatics framework that has been implemented at the University of Missouri (MU). This framework leverages the secondary reuse of MU Healthcare data for cohort identification and retrospective data analysis, and provides an online application for project and data management.

Introduction
Providing informatics applications to support clinical research is of high importance among the research based university hospitals. The Institute for Clinical and Translational Science (ICATS) leads the development of informatics framework (Figure 1) for clinical research at the University of Missouri (a.k.a. Mizzou) Healthcare System. It has two components: (1) a clinical data warehouse, and (2) an online project management tools.

Clinical Research Informatics Framework

Clinical Data Warehouse: We implemented a clinical data warehouse using an open-source system called i2b2 [1]. The data warehouse has two data repositories: identified and de-identified. In the de-identified data repository, protected health information (PHI) is removed following the HIPAA regulations. The users have three levels of access: basic, expanded and full. With basic access, the users can search the de-identified data repository to generate aggregated results. The users can download de-identified data with proper IRB application through expanded access for a certain period of time. The honest broker has full access to identified data repository who deposits PHI data for IRB approved projects in the research data repository.

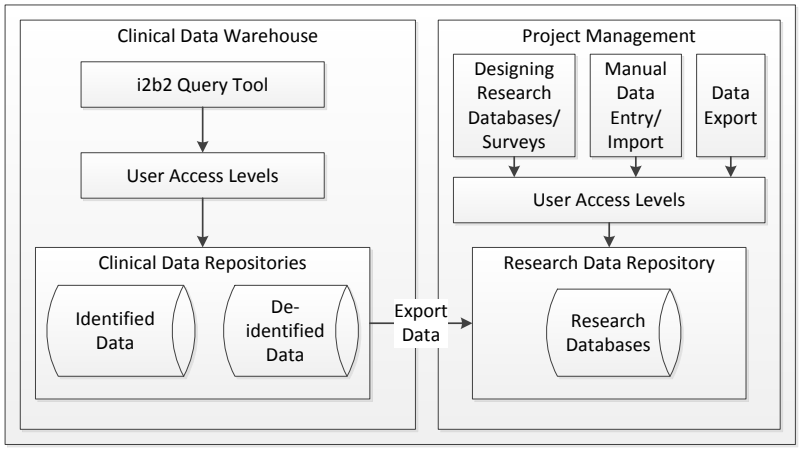

Figure 1: Clinical Research Informatics Framework

Online Project Management: We implemented the REDCap [2] system in which the research/survey databases are created and stored securely. The access levels are controlled based on the user's role in the projects. The study coordinators (e.g. principal investigator) have full access to the projects and data, the data entry users can create and modify records, and the data analysts can download de-identified data only.

Conclusion
A useful informatics framework for clinical research has been implemented as a foundation upon which other tools and resources will be developed.

Developing a Knowledge Base for Detecting Carotid Stenosis with pyConText

Danielle Mowery, PhD[1,5,6], Daniel Franc, MD[2], Shazia Ashfaq, MD[3,4], Tania Zamora, BA[4], Eric Cheng, MD, PhD[2], Wendy W. Chapman, PhD[5,6], Brian E. Chapman, PhD[6]

Abstract: *We present a pilot study to develop a semantic schema for extracting mentions of carotid stenosis and their modifiers from ultrasound reports to extend a natural language processing (NLP) algorithm, pyConText.*

Introduction: 795,000 people suffer strokes each year. Comparative-effectiveness studies can determine whether one treatment is more effective than another for a stroke cohort. However, these studies rely on manual chart abstraction which is expensive and tedious. NLP can help by automatically abstracting carotid stenosis mentions and their modifiers, applying rules to assert the severity of stenosis (no stenosis to severe) for each encounter, and tracking patient responses (severity changes) over time. We developed a model to support this use case.

Methods: In this pilot study, we selected 29 de-identified, carotid ultrasound reports from www.mtsamples.com to develop a schema and guidelines that support information extraction of carotid stenosis mentions (all authors). Two physicians (DF, SA) independently annotated each report and adjudicated each disagreement with consensus review using eHOST annotation tool[1]. For each modifier, we report an example, the frequency (proportion) of stenosis modifications, the partial IAA (F1-score for partial span, same attribute), and the distribution of lexical cues.

Results: We observed 177 **Findings** representing carotid stenosis with the following distribution of modifiers:

Modifier	*Example*	Count (%)	IAA	Lexical cue/regular expressions (Counts)
Finding	Severe *stenosis* observed	177 (--)	96%	*steno(ses|sis)* (111), *occlu(ded|sion)* (26), *carotid|caritid stenosis* (16), *plaque* (10), *wall thickening* (5), *hypoplastic* (4), *carotid|caritid artery disease|stenosis* (4), *atherosclerotic changes* (1)
Existence Indicator	*probable* stenosis	13 (7%)	96%	*no|without evidence* (6), *no* (5), *could be* (2),
Severity Indicator	*45-55%* occlusion	44 (25%)	97%	*less than \d{2}%|(<)\d{2}%* (14), *\d{2}%(-|to) \d{2}%* (10), *(hemodynamically) significant* (8), *mild* (4), *appreciable* (2), *moderate* (2), *complete* (1), *very severe* (1), *near* (1)
Neurovascular Anatomy	*internal carotid* is occluded	44 (25%)	95%	*ica|internal|vertebral|common|external carotid artery|arteries* (34), *carotid(s)* (7), *carotid artery|arteries* (3)
Anatomic Modifier	*proximal* carotid artery	5 (3%)	91%	*proximal* (3), *bifurcation* (1), *cavernous portion* (1),
Sidedness	*R* ICA occluded	43 (24%)	95%	*bilateral(ly)* (16), *r|right(-sided)* (13), *l|left(-sided)* (12), *either side* (1), *both* (1)
Exam Quality	*fully visualized* stenosis	2 (1%)	100%	*not visualized* (2)
Reason for Exam	*REASON:* R/O stenosis	26 (15%)	97%	*assess|eval(uate) for* (12), *r/o|rule out* (7), *?* (3), *reason* (3), *indication* (1)

Conclusions: Most carotid stenosis **Findings** are modified by cues for **Severity Indicator**, **Neurovascular Anatomy**, and **Sidedness**. All modifiers are annotated with high agreement. Most **Severity Indicators** are expressed as a range e.g., "60-69%" or "less than 40%" followed by qualitative expressions e.g., "significant stenosis" or "mild plaque". We are iteratively annotating data and adding new regular expressions and rules to train pyConText[2] to detect carotid stenosis mentions from the Office of Quality and Performance Stroke Study dataset.

A New Alternative for Accessing Medicare Claims Data: The Virtual Research Data Center

Mallika Mundkur, MD[1], Swapna Abhyankar, MD[1], Alex Constantin, PhD[2], Leighton Chan, MD, MPH[2], Clement J. McDonald, MD[1],
[1]National Library of Medicine, National Institutes of Health, Bethesda, MD
[2]Rehabilitation Medicine Department, Clinical Center, National Institutes of Health, Bethesda, MD

Abstract
In November 2013, the Centers for Medicare and Medicaid Services (CMS) launched the Virtual Research Data Center (VRDC), a tool for accessing Medicare claims data[1]. The VRDC enables wider use of these data in a more secure and cost-effective format compared to the previous method of delivering encrypted files to researchers on a CD or hard-drive. We describe key features of the VRDC from an end-user's point of view as a reference for other researchers interested in using Medicare data.

Introduction
The Medicare claims data are a valuable resource for conducting epidemiological and health services research. Historically, CMS provided claims data in the form of encrypted files on CD or hard-drive. The VRDC provides virtual data access and obviates the need for managing physical hardware and file encryption. Interested researchers currently have the option to choose either physical or virtual access to Medicare files.

CMS Data Files Available for Request
More than ten years' worth of data, from 1999 to 2012, are available in electronic format and accessible through the VRDC. This includes claims data from Medicaid, Medicare Parts A (Inpatient), B (Outpatient), and D (Prescription Drugs), the Master Summary Beneficiary File, which includes the National Death Index, and the Medicare Provider Analysis and Review File[2]. The Long-Term Care Minimum Data Set is also available, which includes standardized assessments of physical, psychological, and psychosocial functioning of all patients in a Medicare- or Medicaid-approved long-term care facility.

Request Process and Data Cost
Requesting either the physical or virtual data is a multi-step process, which we will illustrate with a process map on our poster. The cost structure of the VRDC compared to the physical data request is one of the main differences between the two. The cost of the physical data is driven by the number of files and years of data requested; for large data samples this could reach several hundreds of thousands of dollars or more. In contrast, access through the VRDC is fixed per user per year, currently $25,000 for federal and $40,000 for non-federal users. Additional users cost $15,000 per user per year[2]. Our poster will also include a table describing the cost structure in more detail.

Technical Aspects of Data Access
The VRDC is a secure central repository that researchers access via VPN and provides 500GB of disk space per user. The Statistical Analysis System (SAS) Enterprise Guide (EG), is available in VRDC's virtual environment for researchers to conduct statistical analysis, and then download aggregate analysis results. The VRDC must be accessed via a Windows operating system.

Conclusion
We conclude that the VRDC offers a highly secure and cost-effective approach to accessing Medicare data and should be the preferred approach for researchers who want to analyze large samples of the Medicare population.

Facilitating Visual Exploration of System-generated Reasoning Pathways underlying Drug-Side effect Relations

Sahiti Myneni, PhD, MSE[1], Trevor Cohen, MBChB, PhD[1]

[1]The University of Texas School of Biomedical Informatics at Houston, TX, USA

Abstract

Scalable literature-based discovery methods can infer relationships between biomedical entities of interest from large volumes of computable biomedical knowledge. However, exploring these connections is challenging given the combinatorial explosion of possible reasoning pathways connecting the entities. This work provides an interface to explore interesting inferences derived using geometrically-motivated computational models of analogical reasoning. Principles from cognitive engineering, visual analytics and discovery browsing are brought together to develop a novel interaction paradigm for information retrieval systems.

Introduction

Scalable methods of literature-based discovery (such as Predication-based Semantic Indexing) are able to infer a multiplicity of relationships between biomedical entities of interest[1]. Representing the system-generated patterns and supporting evidence in a user interpretable way plays a key role in enabling the biomedical scientists act upon the knowledge extracted by the system from the literature. However, these patterns may represent thousands of unique reasoning pathways. Therefore, new user interaction paradigms are required, to allow users to navigate through underlying evidence efficiently. Unlike conventional document-based search engines, Semantic MEDLINE[2] facilitates summarization and visualization of retrieved documents, motivated in part by principles developed to mediate literature based discovery. It allows users to construct argumentation through iterative combination of key concepts and relations. Inspired by the "discovery browsing" principle[3] that motivates Semantic MEDLINE, we develop a novel interaction paradigm for information retrieval systems that allow users to explore computer-generated reasoning pathways suggesting a plausible relationship between a drug and potential side-effect.

Methods

Techniques from visual and network analytics in conjunction with principles of cognitive engineering and discovery browsing were used. For illustration purposes, we chose to represent the pathways supporting the assertion that "rosiglitazone CAUSES myocardial_infarction". A total of 108100 unique pathways involving 390 unique middle terms were connecting this drug-side effect pair. The middle terms were grouped into 29 UMLS semantic types. We used D3 and Jquery to develop a system for inference visualization and user exploration of the pathways.

Results

As shown in Figure 1, the initial framework consists of four modules. The first module allows the user to choose a semantic type, which consists of a set of middle terms connecting the drug and side effect. The second module allows the user to sort the middle terms using inference metrics and underlying evidence from the literature. The third module allows the user to explore the system-generated reasoning pathways and connecting middle terms by means of collapsible nodes. The fourth module, at the bottom, provides an organizer such that the user can selectively explore aspects of these pathways that are interesting and unusual.

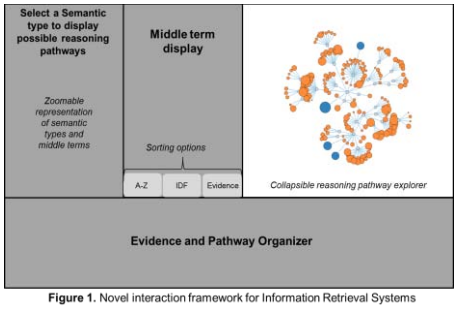

Figure 1. Novel interaction framework for Information Retrieval Systems

Ongoing work

The user interaction framework will incorporate geometrically-motivated models of reasoning within contemporary visualization approaches to provide users with the ability to explore reasoning pathways and literature that supports the hypothesis that a drug and side effect are causally related. More sophisticated user-centered approaches to enable the exploration of pathways in the proposed system will be studied and integrated.

Prevalence of a standardized storage format and next steps for clinicians

Masaharu Nakayama, MD, PhD[1,2]

[1]Disaster Medical Informatics, International Research Institute of Disaster Science, Tohoku University, Sendai, Japan; [2] Medical Informatics Center, Tohoku University Hospital, Sendai, Japan

Abstract

Sharing medical information among hospitals remains challenging due to differences in vendor specifications. A standardized format for storage, the Standardized Structured Medical Information eXchange (SS-MIX), has spread nationwide and has been utilized in several regional and national projects on medical information systems in Japan. The format is mainly divided into two categories: standardized storage and extended storage. The latter should be determined in detail for clinical use.

Introduction

Sharing medical information among hospitals is crucial for patient care. However, the interfacility exchange of patient data is difficult because of differences in vendor specifications. Kimura et al. developed the Standardized Structured Medical Information eXchange (SS-MIX) [1], which enables data from medical record systems developed by different vendors to be stored in a similar format. SS-MIX was modified and released as SS-MIX2 in 2012. Several projects have utilized this format to share and back up patient data in Japanese hospitals[2]. The number of hospitals with Uploader of SS-MIX2 was 216 in June 2013.

Two categories of SS-MIX

SS-MIX2 is divided into two categories: standardized storage and extended storage. Standardized storage includes clinical data in standard form (HL7 v2.5), such as the basic patient data, prescriptions, laboratory results, and disease name registration. These data are easily utilized for secondary use. Other important clinical data, however, have not been structured and should be stored in the extended storage. Therefore, these data should be structured, coded, and standardized.

IHE

The Integration healthcare enterprise (IHE) is an international association that aims to improve the way in which healthcare computer systems share information, and sets profiles for the coordinated use of established standards such as the Digital Imaging and Communications in Medicine (DICOM) and Health Level Seven (HL7). One of the IHE's activities, "connectathon," provides connectivity testing across a variety of vendor platforms and validates the participants' interoperability and compliance with the IHE profile. In Japan, IHE-Japan (IHE-J) is also active in promoting IHE profiles in accordance with the Japanese Health System through collaboration between technicians from vendor companies and clinicians from several hospitals.

An important next step should be the standardization of clinical data from various modalities, such as electrocardiogram, ultrasound cardiogram, and catheterization. IHE-J cardiology has commenced the initial steps for standardization with the help of several academic cardiology societies. This will be critical toward sharing important clinical data, which will benefit specialists who require such data for clinical use and research purposes.

Conclusion

Although SS-MIX has spread nationwide in Japan, clinicians still require extension of structured storage formats for the utilization of clinical data regardless of differences among vendors or modalities. To this aim, standardization should be spread promptly. IHE-J cardiology has begun to standardize data from several modalities in cardiology by collaboration with academic associations. This step will be important for the development of medical care.

Achieving a Better Readability of Instructional Notes in the ICD-10-CM Tabular XML Files

Hari Nandigam MD, MSHI [1], Nima Behkami Ph.D[2]

[1]*Partners Healthcare System, Boston, MA.* [2]*Harvard Medical School, Center for Biomedical Informatics, Boston, MA, Boston, MA*

Introduction and Background: The Center for Medicare & Medicaid Services (CMS) published ICD-10-CM files in xml format in addition to pdf format. The advantage of having tabular and index files in xml format is that they can be uploaded to a database and easily queried. The tabular files published by CMS use colons (:) indicated in the text of the elements such as 'excludes1', 'excludes2', 'use additional code' and 'code first' to indicate that the condition in the first clause applies to the subsequent clauses. However the subsequent clauses are modeled at the same level as the parent clauses. For example the element -<excludes1> in 'G01' contains values such as 'meningitis (in):',' gonococcal (A54.81)', 'leptospirosis (A27.81)' etc. Ideally they are meant to be present as 'meningitis (in) gonococcal (A54.81)', 'meningitis (in) leptospirosis (A27.81)' etc. We came up with a model to explicitly indicate in this way using a transformation tool.

Methods: Using a transformation tool (Altova Mapforce) we loaded the initial version of 2015 ICD-10-CM tabular files and introduced logic to indicate that when the program sees a colon in the text of <excludes1>, <excludes2>, <code first> and <use additional code>, it explicitly indicate the condition before the colon in the second and subsequent clauses. This automation process helped us to handle the issue with <excludes1>, <excludes2>, <code first> and <use additional code>.

2015 ICD-10-CM tabular file	Modified ICD-10-CM tabular file
<diag> <name>G07</name> <desc>Intracranial and intraspinal abscess and granuloma in diseases cla <codeFirst> <note>underlying disease, such as:</note> <note>schistosomiasis granuloma of brain (B65.-)</note> </codeFirst> <excludes1> <note>abscess of brain:</note> <note>amebic (A06.6)</note> <note>chromomycotic (B43.1)</note> <note>gonococcal (A54.82)</note> <note>tuberculous (A17.81)</note> <note>tuberculoma of meninges (A17.1)</note> </excludes1> </diag>	<diag> <name>G07</name> <desc>Intracranial and intraspinal abscess and granuloma in diseases classified elsewhere</desc> <codeFirst> <note>underlying disease, such as: schistosomiasis granuloma of brain (B65.-)</note> </codeFirst> <excludes1> <note>abscess of brain: amebic (A06.6)</note> <note>abscess of brain: chromomycotic (B43.1)</note> <note>abscess of brain: gonococcal (A54.82)</note> <note>abscess of brain: tuberculous (A17.81)</note> <note>abscess of brain: tuberculoma of meninges (A17.1)</note> </excludes1> </diag>

Results: We modeled the tabular xml file and uploaded in the database. Upon submitting a term in the free text field, we get matching ICD-10-CM codes and their corresponding descriptions in the list box. On selecting each term in the listbox, their corresponding values for inclusion terms, Excludes1, Excludes2, Code First and Use additional Code show up in the additional list boxes below.

Discussion and Conclusion: we noticed at the time of this paper that 2015 version of ICD-10-CM is better than the older versions in explicitly indicating about the clauses. However we noticed the discrepancies with colons weren't handles in a consistent manner. Automation of this process will be very useful. A manual review is always recommended to verify if right changes are done by doing a comparison of the initial and final files. We took care not to deal with colons indicated within the elements such as 'visualImpairment', 'SevenChrNote' and 'Notes' in the tabular file. This transformation/tweaking of the tabular xml file helped in better expressivity, readability and understandability of the instructional notes

The Can (thecan.apphb.com): a repository of decision support rules relating to laboratory tests

Scott D. Nelson, PharmD;[1,2] R. George Hauser, MD[3]
[1] Department of Veterans Affairs Medical Center, Salt Lake City, UT; [2] University of Utah, Salt Lake City, UT; [3] Laboratory Medicine, Yale-New Haven Hospital, New Haven, CT

Abstract
Clinical decision support (CDS) in health care has an important role in improving quality and appropriateness of patient care. We set out to develop a self-sustaining repository of best-evidence CDS rules for laboratory test ordering and interpretation through networking and collaboration. The first stage consists of the development of a rules repository (thecan.apphb.com), and populating it with laboratory monitoring rules. The second stage consists of developing a method for converting the natural language CDS rules into computable rules using a layered framework with and rule validation. The input of rules into the repository, "The Can", is accomplished through networking and collaborative efforts. For more information, and to participate, please visit: thecan.apphb.com

Background
Clinical decision support (CDS) in health care has an important role in improving quality and appropriateness of patient care. While much effort has been given to CDS in medication ordering, there is also a need for CDS in laboratory test ordering and interpretation. The challenge is that the practices of medicine and laboratory pathology are constantly changing, and a single organization may not have the resources and funding to create all of their own CDS rules. Additionally, while lab utilization research has been around for a while, finding a list of rules or recommendations is difficult. Therefore a method for creating, sharing, and updating CDS rules related to laboratory testing is needed.

Project goal
We set out to develop a self-sustaining repository of best-evidence CDS rules for laboratory test ordering and interpretation through networking and collaboration methods. The repository is named "The Can".

Methods
The first stage of the project is to create a repository for the laboratory test rules, and populate it with rules using natural language. We will recruit subject-matter experts (SMEs) with an interest in laboratory testing or lab utilization from outside our development committee for the input of laboratory test CDS rules. Market campaigning and recruitment of SMEs will be done through scientific meetings, professional panels, and peer-reviewed literature publications. These experts will then be asked to recruit others to contribute to and use the CDS repository. Similar successful attempts at this type of collaborative effort for placing expert knowledge into a community repository, due to usefulness of their content, are that of Stack Overflow and Wikipedia. SME input and use will be driven by repository content due to the difficulty of finding CDS lab rules from other sources. To encourage the generation of content in the repository, we have developed the website with priorities in access and usability. The website will help guide SMEs through a structured process for defining their CDS rules to facilitate later conversion to a computable format, using a layered framework. This common rule repository developed by SMEs will help empower SMEs (and their organizations) to use and trust the repository, increase collaboration between organizations, and keep 'The Can' flexible and adaptive to current user needs and the constantly evolving field of medicine. In order to increase evidence-based external validity and generalizability, the rules in the repository require at least one reference and peer review for validation. Ideally, the rules in 'The Can' would be computable and interoperable across systems; however, the current lack of national interoperability requires that institutions translate the rules into their specific systems. The second stage of the project consists of developing a method for making the CDS rules computable by mapping to terminology standards and through validation and curation process. While not currently computable, 'The Can' provides a repository for sharing CDS rules and promotes future interoperability.

Conclusion
To date, there have been over 100 validated rules added to the repository, with 9 collaborating organizations. While the project is new and currently a content repository in the first stage, we are piloting the implementation of some of the rules at a local institution. By networking and collaborating with other SMEs for CDS rule development, we will develop a scalable and up-to-date repository of laboratory test utilization and interpretation CDS rules. 'The Can' is a valuable resource for laboratory CDS rules. For more information, and to participate, please visit: thecan.apphb.com

RxClass - Navigating between Drug Classes and RxNorm Drugs

Thang Nguyen, M.S., Lee Peters, M.S., and Olivier Bodenreider, M.D., PhD
U.S. National Library of Medicine, National Institutes of Health, Bethesda, Maryland, USA
Contact information: RXNAVINFO@LIST.NIH.GOV

Motivation

Drug classes constitute important information about the drugs and are critical to important use cases, such as clinical decision support (e.g., for allergy checking). *RxNav*, our RxNorm browser, already displays the classes for RxNorm drugs, but its drug-centric perspective does not accommodate the exploration of drug classes. This is the reason why we developed a web-based companion browser, *RxClass*, which supports navigation between RxNorm drugs and drug classes from several sources, including ATC, MeSH, NDF-RT and Structured Product Labels from the Food and Drug Administration (FDA).

Drug Class Sources

The Anatomical Therapeutic Chemical drug classification (***ATC***) is a resource developed for pharmacoepidemiology purposes by the World Health Organization Collaborating Centre for Drug Statistics Methodology.

The Medical Subject Headings (***MeSH***), developed by the National Library of Medicine (NLM), provides a rich description of pharmacological actions for the purpose of indexing and retrieval of biomedical articles.

The National Drug File-Reference Terminology (***NDF-RT***), developed by the Department of Veterans Affairs, provides clinical information about drugs (therapeutic intent, mechanism of action, etc.) and integrates drug classes from FDA's Structured Product Labels.

Linking RxNorm Drugs to Drug Classes

Like *RxNav, RxClass* is supported by functions from an application programming interface (API), which can be used independently for integrating drug class information in programs. The API serves the latest information available from the drug information sources.

RxClass provides a graphical interface to explore the hierarchical class structures of each source and examine the corresponding RxNorm drug members for each class. Some features of *RxClass*:

- The user can navigate through the drug classes via the hierarchical menu, or use the search feature to identify a drug class or RxNorm drug.
- Drug class member results can be saved to a file in several different formats.
- Users of *RxNav* can link to *RxClass* to get class members.

A sample screenshot of *RxClass* is shown in Figure 1.

Conclusions

Providing drug class members has long been a missing piece of information in *RxNav*. With *RxClass*, we now provide a link between drug classes from various sources and RxNorm drugs.

RxClass is available from the main *RxNav* website (http://rxnav.nlm.nih.gov), along with additional information about *RxNav* and our APIs to various drug information sources.

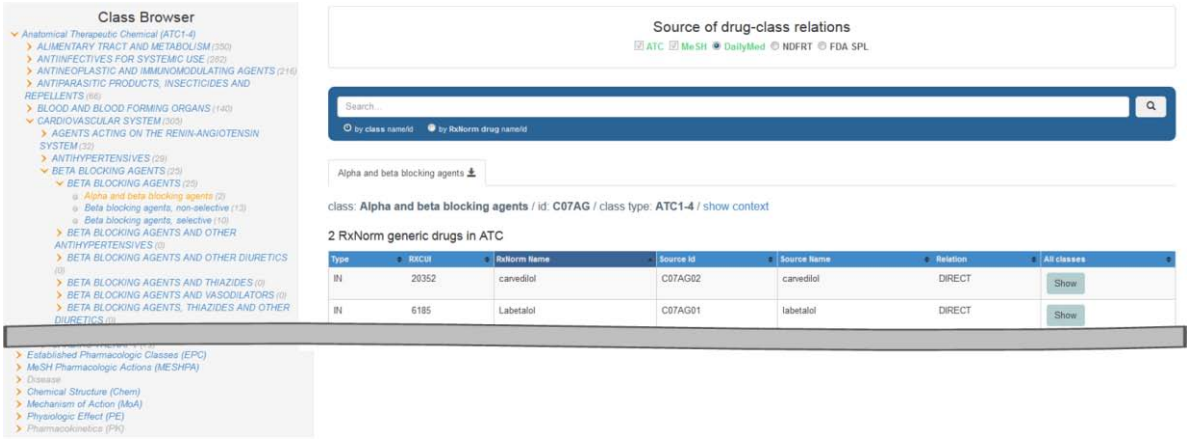

Figure 1. Sample screenshot of RxClass

Patients and providers using secure messages on the patient portal for home telemonitoring: what are the informatics challenges and how can they be managed?

Frederick North, William Ward, Muhamad Elrashidi, Karen Ytterberg, Barbie Mundt, Eric Manley, SidnaTulledge-Scheitel

Introduction: Home telemonitoring is available for a number of patient measurements including blood pressure, blood glucose, weight, and oxygen saturation among others. Telemonitoring has generally sent data directly from a home monitor to an in home hub which then transmits data to a server. The patient portal has opened up another secure platform for telemonitoring data. Patients can self monitor blood pressure, glucose and other parameters and send the results to their provider in a secure portal message. We examined all secure messages to the Mayo Clinic patient portal from 2012 to determine use, quality and outcomes of messages for telemonitoring blood pressure.

Methods: We searched all 56,000 Mayo Clinic Rochester patient-generated secure messages from 2012 for content concerning blood pressure. We performed a detailed review on a random sample of 200 blood pressure messages. Measures for review included blood pressure reading counts, type of blood pressure data (individual readings, averages, and blood pressure range). We also examined whether the data provided was sufficient to treat blood pressure with a new medication. The message was evaluated for the blood pressure context (follow up blood pressure or specific elevated blood pressure concern). We captured the provider secure message response to the patient-generated blood pressure message and determined outcomes of prescriptions for antihypertensives, change in medication dose or if an appointment was suggested.

Results: Almost 1% of the 56,000 secure messages contained content about blood pressure. Of those messages with blood pressure content, the information was quite variable. Patients sent qualitative information (my blood pressure is too high) and qualitative information (blood pressure averages, ranges, and individual readings). Some sent lists of blood pressure readings. There was little specific information on dates the blood pressure was recorded, time of day, or conditions (during rest or activity). Few of the patient-generated messages had any evidence of medication reconciliation, pharmacy information, or other information usually needed to respond with a medication dose change or change in medication (new prescription). Provider responses also varied. There were responses to change medications and to start new blood pressure medications.

Conclusion: Patients and providers are using secure messages on the patient portal for blood pressure telemonitoring. Despite blood pressure content that is highly variable, providers respond with secure messages containing instructions for changes in medication and new antihypertensive medications. Our findings demostrate the informatics challenges of using secure messages on the patient portal for blood pressure monitoring. We suggest a specific template with required patient provided fields as an approach to managing patient-generated secure message home blood pressure readings. This could help standardize home blood pressure monitor readings for incorporation into the EMR. The template also requires patients to include other medication and pharmacy preferences so that providers have sufficient information to make medication changes.

Attitudes Towards Electronic Medical Records in Intensive Care

John C. O'Horo, MD, MPH, Pablo, Pickering, Vitaly Herasevich MD, PhD

Abstract: The degree to which electronic medical record (EMR) systems fit into intensive care unit (ICU) workflows is not well studied. We conducted a survey of critical care providers to determine the degree to which current systems fit their needs. Generally, EMRs were perceived as containing useful information, but not presenting it in a user friendly way that facilitates patient care in this setting.

Introduction: The fast pace of the intensive care unit (ICU) demands readily accessible and up to date data. However, most electronic medical records (EMRs) are designed for the outpatient or general care inpatient setting, and are not optimized for the ICU environment. As part of the implementation of a novel ICU EMR interface, the Ambient Warning and Response Evaluation (AWARE) system, we collected baseline data on attitudes towards the EMR in ICU providers.[1]

Methods: Critical care providers, including physicians, nurse practitioners, physician assistants, respiratory therapists and nurses, were surveyed at two tertiary care clinical campuses (Mayo Clinic Arizona and Florida). Providers were asked 10 questions about how accurate and user friendly the current EMR is on a 5 point Likert scale, with 5 being strongly agree, and 1 being strongly disagree. For summary analyses, both 4 and 5 were considered agreement, and 1 and 2 disagreement. Results were analyzed using JMP 9.0 statistical software (SAS, Cary, NC).

Results: We received responses from 233 providers; 63% of respondents were nurses, 24% respiratory therapists and the remainder physicians and midlevel providers. Most (89%) had worked in the ICU for more than a year, and the majority (62%) for more than 5 years. Ninety-four percent had worked with the existing medical record for at least a year. Overall, the majority of users thought the current EMR provided accurate information relevant to provider needs. However, fewer users were satisfied with the time required to use the EMR, with only 60% of users agreeing or strongly agreeing with the statement "I get the information I need in a timely manner using the EMR." Only 51% thought that the current EMR provides information in a useful format. More than 1/3 of providers thought he EMR made data gathering challenging. 55% felt that EMR use decreased the amount of time spent with patient/family. Prescribing providers (physicians, NP/PA) were more likely to be critical of the layout and efficiency of the EMR than non-prescribing providers.

Conclusion: Although the content of the current EMR provides relevant and accurate data, providers were not satisfied with the way in which data was presented. We will aim to improve these interface and efficiency issues with the novel AWARE interface.

Question	Prescribing providers	Nonprescribing providers	P value
The Electronic Medical Record (EMR) provides the precise information I need.	3.53 (1.10)	3.96 (0.81)	<0.01
The information content in the EMR meets my needs	3.66 (1.07)	3.99 (0.71)	0.10
The EMR provides me with sufficient information	3.75 (0.92)	4.02 (0.65)	0.11
I get information I need in a timely manner using the EMR	3.06 (1.22)	3.56 (1.03)	0.04
The EMR provides up-to-date information	3.69 (0.90)	3.85 (0.83)	0.34
I am satisfied with the accuracy of the EMR	3.59 (0.91)	3.92 (0.75)	0.06
I am satisfied with the way information is presented in the EMR, it is provided in a useful format	2.72 (1.25)	3.40 (1.12)	>0.01
The EMR makes the task of data gathering difficult/demanding	3.09 (1.17)	3.05 (1.13)	0.84
The EMR's display is designed to help increase patient safety	2.81 (1.23)	3.50 (0.97)	<0.01
The EMR's design facilitates more timely interventions	2.97 (1.18)	3.21 (1.02)	0.27
The time spent on data gathering through EMR reduces the time spent with the patient/family.	3.66 (1.15)	3.35 (1.13)	0.16
The ICU team discussion is encouraged by EMR's design	2.78 (0.91)	3.08 (0.86)	0.09

Table: Responses of 233 providers to individual survey questions. All questions were on a 5 point scale, where 1 was "strongly disagree" and 5 "strongly agree." Mean scores are presented with the standard deviation in parentheses. "Prescribing" providers were physicians, nurse practitioners and physician assistants. Non-prescribing providers were registered nurses and respiratory therapists. P values calculated using t- test.

Temporal patterns of alerts generated by a medication order-auditing program

Kevin O'Bryan MD[1], Charles H Andrus, MHA[1], S. Paul Hmiel MD, PhD[2], Phillip Asaro MD[2], Feliciano Yu, MD, MSPH[2,1] St. Louis Children's Hospital, St. Louis MO; [2]Washington University School of Medicine, St. Louis MO

Abstract

Pediatric drug dosing rules, embedded in computerized clinician order entry systems, may provide an additional mechanism to avoid adverse drug events. Alerts generated by a custom dose-range checking and auditing system were evaluated by medication, as well as by day of week (weekday vs. weekend) and shift (morning, afternoon, evening and early morning). Three medications represented nearly 65% of the total, with distinct increases in the number of alerts on weekends, and during the night and early morning shifts.

Introduction

Clinical decision support (CDS) engines provide a mechanism to provide relevant guidance to clinicians providing complex care. Alerts generated by these systems can provide insight into the complexities of clinical care, potentially identifying weaknesses of current practice, and opportunities for improving CDS. Medication dosing rules for infants and children are special example complex care, as the clinician needs to consider many factors in prescribing high-risk drugs. We previously described a robust dose range checking system that allows for complex medication dosing rules, while simultaneously producing few nuisance alerts. We now describe the temporal pattern of alerts generated by this system.

Methods

St. Louis Children's Hospital is a 275 bed tertiary care academic hospital, a member of the BJC Healthcare System, and affiliated with the Washington University School of Medicine. It includes a 75 bed neonatal intensive care unit, a 26 bed general Pediatric Intensive care Unit and 12 bed Cardiothoracic Intensive care unit, as well as general medical, surgical, oncology, and neuroscience units. Each unit is staffed by pediatric and surgical residents, supervised by subspecialty fellows and full time faculty, with a dedicated clinical pharmacist available for morning rounds, and throughout the day for consultation. A dose range checking and auditing system was developed as an adjunct clinical decision support system to provide more comprehensive information to clinicians, expanding on the vendor supplied dose range checking features of the EMR.
When the rule was applied to an order, it could result in any of 3 alert stop types: warning (user can proceed without a comment), soft stop (user must comment to proceed), hard stop (user cannot proceed). A real-time dashboard assesses alert effectiveness and user response.

Results

During the study period, a total of 2597 alerts were generated from thirty-three active medication-dosing rules. Alerts were most frequent for acetaminophen, representing 48.2% of total alerts, with other medications at <10%. Two high risk medications, morphine and clonidine, represented 9.1% and 6.4% of the alerts.
When analyzed by day of the week (weekend vs. weekday), a disproportionate number of alerts occurred on weekends (Saturday or Sunday), with 80.8% of acetaminophen alerts occurring on weekends, with similar results for morphine (80.1%) and clonidine (80.6%).

Time of day was grouped as morning (0600 to 1200 hr), afternoon (1200 t0 1800 hr), evening (1800 to 2400 hr) and early morning (0000 to 0600 hr), with the greatest number of alerts (1051) generated during the morning, when most medication orders are generated. The absolute number of alerts during the afternoon, evening and early morning, were similar, at 729, 561, and 411, respectively, in parallel with the decreasing number of overall orders during these time periods. The alert rate, expressed per total orders, was markedly higher during the night and early morning periods, however. Acetaminophen was again most common, representing 53.3% of night and 48.4% of early morning alerts, followed by morphine and clonidine.

Conclusion

Three medications, acetaminophen, morphine and clonidine, were responsible for nearly two thirds of the total alerts. A distinct temporal pattern of drug alerts was noted, with increased alerts on weekends, as well as during early morning and nights. This pattern may reflect the availability of the unit based clinical pharmacists in recommending and monitoring medication orders.

An exploratory factor analysis of socio-demographic and contextual factors associated with Dominican women concerned about HIV/AIDS

Michelle Odlum, BSN, MPH, EdD[1] and Suzanne Bakken, RN, PhD[1, 2]
Columbia University School of Nursing[1], Department of Biomedical Informatics[2], New York, NY;

Introduction

The feminization and ethnic diversification of the HIV epidemic, has resulted in a call for the development and evaluation of gender and culture specific HIV prevention strategies for high risk groups including Latinas[1]. The steadily changing demographic profile of the AIDS epidemic, challenges HIV prevention strategies to remain relevant and up-to-date. The long-term goal of this program of research is to develop a culturally-specific, literacy appropriate, smartphone-based, self-management intervention for Dominican women midlife and older. However, little is known about the HIV sexual-risk behaviors and the socio-demographic and contextual factors of Dominican women in all age groups. This preliminary research seeks use the Theory of Gender and Power (TGP) [2] theoretical framework to identify social/societal factors that may influence women's sexual risk behavior and targets for intervention.

Methods

The three constructs of the TGP will be used to guide the characterization of factors that potentially contribute to HIV sexual-risk behaviors. Items from a community-based survey, relevant to the TGP constructs of: 1) Affective influences/social norms; 2) Gender-specific norms and 3) Power and authority were considered for inclusion. Exploratory Factor Analysis (EFA) was conducted to identify latent constructs underlying items categorized under the three constructs[3]. Casewise deletion of missing data was conducted for all included items[4]. The final sample (N=205) was used in the EFA. Factors were extracted and orthogonally rotated using the varimax method. Solutions of two to five factors were examined for the TGP constructs. Factors were extracted based on the examination of eigenvalues, scree plots and latent construct interpretation.

Results

The original 28 items were reduced to 22 items. The EFA measurement model items were identified and two latent constructs were derived for each theoretical construct[3]. Affective influences/social norms: were characterized by Internet use and spending time with others. Gender-specific norms: were characterized by: food security, education and employment. Power and authority: was characterized by perceptions of perseverance and control (Table 1).

Table 1. Rotated Factor Loading for EFA with Varimax Rotation

Affective influences/social norms	**Factor**	
	Internet Use/ Social Circles	**eHealth seeking/Social Networking**
Item 1: Spend time with some don't live with you	-0.577	-
Item 2: Internet use	0.358	-
Item 3: Household members eHealth information seeking	-	0.556
Item 4: Social networking (Facebook, MySpace, or Twitter)	-	-0.312
Gender-specific norms	**Factor**	
	Food Security	**Education and Employment**
Item 5: Household not eat quality/variety of foods due to money	0.798	-
Item 6: Household not eat due to money	0.688	-
Item 7: Education	-	0.689
Item 8: Working for pay	-	-0.314
Power and authority	**Factor**	
	Perseverance	**Control**
Item 9: Doing things that other people thought could not be done	0.657	-
Item 10: Hard work has really helped me to get ahead in life	0.636	-
Item 11: Anything is going to be done right, I have to do it myself	0.633	-
Item 12: Important to do things in the way I want to do them	0.620	-
Item 13: Stand up for what I believe in, regardless of the consequences	0.594	-
Item 14: Stay with it until the job is completely done	0.539	-
Item 15: Don't let personal feelings get in the way of getting a job done	0.460	-
Item 16: Could make life pretty much what I wanted to	0.447	-
Item 17: Confident about ability to handle your personal problems	-	0.839
Item 18: Effectively coping with important changes in life	-	0.792
Item 19: Things were going your way	-	0.472
Item 20: Upset because of something that happened unexpectedly	-	-0.32
Item 21: Felt unable to control the important things	-	0.309

Only factors loading at ¦ = .3¦ are presented

Conclusion

The results of the EFA suggested a factorial structure for constructs of TGP. The latent constructs identified give insight into community-level factors to inform the content development for our smartphone-based, self-management intervention for HIV risk reduction.

Clarifying requirements chronological visualization of medical data by investigating medical journal articles

Keisuke Ogawa, MS[1], Kazunori Matsumoto, MS, PhD[1], Masayuki Hashimoto, MS, PhD[1], Akiko Shibuya, RN, PHN, PhD[2], Yoshiaki Kondo , MD, PhD[2]
[1]KDDI R&D Labs, Saitama, Japan; [2]Nihon University School of Medicine, Tokyo, Japan

Abstract

To clarify the requirements for the chronological visualization of medical data, we performed a literature search of medical journal articles that presented data visualization methods (literature review). We found that the chronological visualization of medical data varied according to the type of research being conducted. In particular, the forms of visualization and time spans in animal experiments differed significantly from those in other types of research. By conducting this investigation, we were able to clarify the differences in the requirements for each type of research.

Introduction

An increasing amount of data is being stored in medical information systems. In hospital settings, the use of laboratory tests is increasing considerably[1]. In order to support the handling of such *medical big data*, medical data visualization systems have been proposed for a range of medical situations such as diagnosis, clinical trials, and medical research[2, 3, 4]. However, the scope of possible requirements for the representation of medical data is not yet clear[5], making it difficult to establish the appropriate representation capabilities for a chronologically based visualization system.

Methods and Results

We analyzed the potential requirements for medical data visualization systems by investigating the data visualization methods presented in medical journal articles (medical graphs). In this paper, we categorize the articles into three types of medical research[6] (cohort studies, animal experiments, and in-vitro experiments) and examine how medical data are displayed in chronological graphs and the associated time spans. We decided to focus our investigation on articles about chronic diseases, especially diabetes mellitus, because the treatment duration tends to be long in such cases. For this study, we selected 230 graphs from 44 articles in the top three diabetes-related journals (that have "diab" in the title and high impact factors) published in January 2012. The investigation results are shown in Tables 1 and 2.

Table 1: Data visualization methods(graph count)

AIC

	Flow chart	Polyline	Vertical bar	Horizontal bar	Table	Scatter plot	Total
Animal exp.	11	69	16	5	13	1	115
†1 Cohort study	3	24	1	0	22	0	50
†2 In-vitro exp.	2	16	12	0	0	0	30
†3 Misc(6 kinds)	9	26	0	0	0	0	35
Total	25	135	29	5	35	1	230

Table 2. Average time span (graph count)*

F-test

	~1 hour	~1 day	~1 week	~1 month	~1 year	~1 century	Variance of time spans(normalized)
Animal exp.	10	57	4	4	22	0	0.08
‡1 Cohort study	3	0	0	1	0	43	0.03
‡2 In-vitro exp.	1	7	14	1	0	0	0.04

*Only those graphs having explicit time spans are counted in Table2

From Tables 1 and 2, it can be seen that there are significant variations in the ways these graphs are presented and the time span in *animal experiments* varies far more than in the other two types of research. The differences are statistically significant. We performed a cross-table analysis using the Akaike Information Criteria[7] and performed an F-test on the time-span variances; AIC differences between dependent and independent models are -98.9(† 1 in Table1), -74.5(† 2 in Table1), and -69.6(† 3 in Table1). P-values are 0.001 (‡ 1 in Table2) and 0.02(‡ 2 in Table2). We concluded that the requirements for chronological visualization of medical data vary according to the type of research. In particular, it was found that representation varies depending on the type of research and that the time spans adopted in *animal experiment* are significantly different from those in cohort and in vitro studies. Satisfying such diverse needs will require systems that allow the user to present and examine data using a wide range of time spans.

Conclusion

This study clarified that the requirements for the chronological visualization of medical data vary according to the type of research. In particular, chronological representations differ depending on the research category and the time spans in animal experiments are significantly different from those in other types of medical research.

Perceptions of Health Care Quality in an Emergency Department During a Planned Electronic Health Record Downtime

Author Block *Amit M. Mehta, Nnaemeka G. Okafor*. University of Texas - Health Science Center at Houston, Houston, TX

Abstract:
Study Objectives:
To evaluate the impact of an Electronic Health Record (EHR) system downtime on health care quality in an emergency department (ED). Health care quality is defined by The Institute of Medicine using six aims: safe, effective, timely, efficient, patient centered and equitable. As more hospitals implement EHR systems, there is a need to understand how those six aims are affected when the EHR systems are unavailable.
Methods:
The project was conducted in an academic ED with 70,000 annual visits and a commercial enterprise-wide EHR system. The ED Informatics Division created a Downtime Summary questionnaire aimed at understanding the clinician's perception of the health care quality issues during the planned 12-hour EHR downtime. The standard EHR downtime protocol included patient care documentation, blank ordering forms, and a whiteboard in each ED care area for tracking patients, diagnostic testing and clinician assignment status. For this project, all ED technicians, nurses, and clinicians were instructed to document any perceived safety (harm to the patient), timeliness (delays in care), effectiveness (missed evidence-based interventions) or inefficient processes attributable to the downtime on the questionnaire attached to every patient chart. The questionnaire forms were then collected from each patient chart.
Results:
A total of 80 patients were evaluated in the ED during the EHR downtime, only 69 (86%) questionnaires were retrieved with any information. 52% of the patients evaluated were discharged, 4% were hospitalized, 39% were still in process, and the remaining 3% were transferred, eloped or left against medical advice. There were no reported issues related to patient safety. The only reported quality issue related to effectiveness was the lack of utilization of approved order sets. Quality issues related to timeliness centered on delays in provider notification of imaging and laboratory results often leading to multiple calls by ED providers to determine the status of these tests. The vast majority of quality issues were regarding inefficient processes. The reported inefficient processes included: difficulty locating newly roomed patients and their respective charts, difficulty finding the appropriate forms to place orders or complete patient care dispositions, problems accessing radiology images or reports and inefficient patient, diagnostic testing and clinician assignment status tracking using the boards. The boards frequently contained incomplete information because they could not be updated in real-time and had a limited physical size. Providers did not review the boards regularly because of their stationary location and limited information.
Conclusion:
The impaired ability to track patient status and diagnostic data, which is typically provided by the EHR track board, resulted in inefficient processes due to the decreased situational awareness of the providers. Development of methods to remotely track these elements during a downtime is an important aspect of maintaining health care quality in an ED.

Decomposition of Quality Requirements to Evaluate Electronic Health Records Systems

Marília E. S. Oliveira, Ms[1, 3], Magdala A. Novaes, PhD[2, 3], Alexandre M. L. Vasconcelos, PhD,[1]

[1]Center of Computer Science of Federal University of Pernambuco, Recife, PE, Brazil;
[2]Internal Medicine Department, Federal University of Pernambuco, Recife, PE, Brazil;
[3]Telehealth Center, Clinics Hospital, Federal University of Pernambuco, Recife, PE, Brazil;

Abstract

Quality evaluation of Electronic Health Record Systems (EHR-S) is an important point of discussion in relation to implantation and acceptance of this kind of system. This work presents the application of a requirements decompose method to evaluation of EHR-S in relation to requirements that is scope of Brazilian Certification for Electronic Health Record Systems – SBIS-CFM Certification. A case study has shown, like initial results, this method may contribute to EHR-S evaluation in relation to SBIS-CFM Certification.

Introduction

Technical standards and certifications have been created in order to establish the minimum requirements expected for EHR-S. On the other hand, EHR-S suppliers should to introduce in their process development an evaluation step for check their products systems according to these requirements. [1] However in some case, these requirements are not expressly verifiable and may bring different interpretations to the reader. This characteristic may become more difficult conduce the evaluation process.

This work presents the initial results of a case study that has evaluates an EHR-S in relation to requirements of SBIS-CFM Certification [2] using a method for decompose quality requirements in minor quality attributes. [3] The aims were analyze if this strategy would help EHR-S suppliers teams to clarify the understanding about requirements and audit test scripts when evaluate their software products, before submitted its on official certification process.

Methods and Results

This work has used official test scripts of Brazilian Certification for Electronic Health Record Systems, SBIS-CFM Certification, and has produced a new evaluation test suit adding a set of help questions to each test script. Test scripts have been decomposed in a set of minor checkpoints that include examples and test data options. Objective of the checkpoints was become more easy identify if the respective requirement was met or not.

Case Study was executed at Telehealth Center of Federal University of Pernambuco and its objective was verify if proposed evaluation method may help Telehealth center team to conduce a internal evaluation in its EHR-S in relation to SBIS-CFM Certification. For each test script, at first moment, participants had to try to execute only official script and after that, they could use respective help questions. During study, it was possible note that participants had to use the help questions to solve their doubts in 39% of total test scripts.

Conclusion

Decompose test scripts in help questions may help the developer team conduce previous evaluations in their EHR-S in relation to SBIS-CFM Certification requirements.

Employment of Penalized Models to Predict Cognitive Domain Performance Using Proteomics

Shauna M. Overgaard, MHI, S.Charles Schulz MD, Gyorgy Simon, PhD
University of Minnesota, Minneapolis, MN

Abstract

Detection and quantification of protein levels may lead to the differentiation of illness-type and the development of diagnostic tests to earlier identify vulnerable patients. Our objectives are to i) employ ridge regression analysis and adaptive lasso in the identification of biomarkers associated with cognitive deficit, and to ii) test the ability of the identified biomarkers to differentiate illness severity groups. Distinct biomarkers are associated with validated deficits shown to differentiate illness groups.

Introduction

Challenges in psychiatric medicine have motivated endophenotype identification and integration of dimensional approaches to diagnosis. Detection and quantification of protein levels may lead to the differentiation of illness-type and development of diagnostic tests to identify vulnerable patients prior to frank symptom manifestation. Schizophrenia is marked by a decrease in cognitive performance[1]. The MATRICS[2] Consensus Cognitive Battery (MCCB) is employed to test seven cognitive domains demonstrated to be effected by schizophrenia: Speed of processing, Attention/Vigilance, Working memory, Verbal learning, Visual learning, reasoning and problem solving, and social cognition. The primary objectives of the analysis are to i) identify proteomic (analyte) predictors that are associated with deficits in the seven cognitive domains and to ii) quantify their ability to distinguish between illness severity groups (control, prodrome, schizophrenia).

Materials and Methods

To achieve our first aim of identifying analyte predictors for each standardized MCCB domain score, we employed adaptive lasso regression. To evaluate whether the resultant analytes can better differentiate between the three disease severity groups than analytes that are not necessarily associated with a cognitive domain deficit, we built a baseline ridge[3] regression model that predicted disease severity based on all analytes. We then built a "differential" regression model to predict the disease severity group based on the analytes identified in our first aim. This was achieved by including the prediction of the baseline ridge model as offset. Analytes that are significant in the second (differential) model can distinguish between the severity groups better than the analytes that are not necessarily associated with a cognitive domain.

Results

Cognitive domain scores known to predict schizophrenia yield predictive value for prodrome classification. Handedly, the levels of analytes that are predictive of cognitive domain are significantly different between clinical groups. The resulting predictions of the ridge regression analysis using MCCB domain scores yielded a receiver operating characteristic area under the curve (ROC-AUC) of .80 for classification of schizophrenia, .79 for Prodrome and .50 for controls. The resulting predictions for the ridge regression using protein analyte predictions of diagnostic class yielded a receiver operating characteristic area under the curve (ROC-AUC) of .78 for classification of schizophrenia, .76 for Prodrome and .64 for controls. Using adaptive lasso, protein phenotypes that appear to support a deficit in working memory and verbal memory are identified. Distinct biomarkers are associated with validated cognitive domains shown to differentiate illness groups. The data contribute to a foundation for a clinical model integrating biomarkers and behavioral indicators associated with early identification and intervention of schizophrenia.

DIGITILIZATION OF THE MULTIDISCIPLINARY MEDICAL INTENSIVE CARE UNIT CHECKLIST

Latifat A. Oyekola, MD [1,2], John T. Finnell, MD , MS[1,2]
[1]Indiana University School of Medicine, Indianapolis, IN; [2]Regenstrief Institute Indianapolis, IN

Abstract With the wide adoption of the electronic health record systems, it is imperative to incorporate existing paper based checklists in medical practice as part of the electronic health record. It is important that checklist is self-developed, precise and operationally suited.

Wishard-Eskenazi Health Hospital in Indianapolis, Indiana is in the process of automating the MICU checklist.

Introduction and Background Checklists can be effective tool to improve care processes and lead to better outcome. Checklists are common in some medical fields like surgery, intensive care unit and emergency medicine. The implementation of multidisciplinary daily rounding checklist in the intensive care units has been shown to reduce mean ventilation-associated pneumonia, reduce mean catheter-related blood stream infection and in the process improve the quality of care while also reducing cost.

Method The MICU team indicated their interest in automating the multidisciplinary paper-based checklist which they call the 'Orange Sheet". The Clinical Informatics team analyzed the workflow of the MICU team after which a meeting with the stakeholders (MICU team) was convened to clarify terms used in the existing paper form and define the functional requirements of the software.

Results Some of the requirements desired were the ability of the software to interact with the users, reminder and prompting ability, messaging features, pre-populate antibiotics, hyperlink to evidence –based practices, leveraging this in multiple spaces (for example order interface) and it's use as part of nursing care plan.

Conclusion The first meeting between the developers of the electronic medical record system (the New Gopher) raised questions about some of the functional requirements specified which could not be immediately addressed as the developers brainstorm on the design for the project. This project is ongoing and is expected to follow the sequence outlined in the diagram.

Differences in Occurrence and Recorded Times of Care Delivery Events as Documented in Electronic Health Records

Mustafa Ozkaynak, PhD[1], Oliwier Dziadkowiec, PhD[1], Sara Deakyne, MPH[2], Tiffany Callahan, BA[1], Eric Tham, MD, MS[1,2]
[1]University of Colorado, Aurora, CO; [2]Children's Hospital Colorado, Aurora, CO

Abstract

Electronic Health Record (EHR) systems can serve as rich data sources to examine clinical workflow. We extracted event logs for every encounter that took place in an academic hospital emergency department and its satellite urgent care sites in 2013. We identified delays between the occurrence and the recorded times of care delivery activities. Workflow researchers should consider these delays to ensure event sequences are captured accurately when using EHR systems as a data source.

Introduction

Electronic Health Record (EHR) systems automatically capture massive numbers of clinical and non-clinical data related to patient care. Although EHRs were designed and are primarily used for patient-care purposes, secondary use of these data can potentially provide with workflow-characterization insights[1]. However, meticulous use of such data source is required for a valid data analysis and interpretation. The purpose of this study is to examine the differences between time of activities and their documentation time of these activities as recorded in the EHRs. Understanding these time differences will inform the reliable and systematic use of EHRs for workflow analysis.

Methods

We extracted event logs for each encounter that took place in the emergency department (ED) of an academic hospital and its satellite urgent care sites in 2013. Our analysis included a total of 2,815,568 events from 133,586 visits by 88,936 patients. Data extraction included the following data elements: activity type, activity occurrence and activity recording times. Activity occurrence is the time that is displayed in the EHR as the time the event occurred, which may be changed manually by a staff member for some events. Activity recording time is the timestamp in the system when the information was recorded.

Results

We identified 966,821 events (34.3% of all recorded events) that were recorded after they occurred. The most frequent five events that recorded after their occurrences are given in Table 1.

Table 1. The five most frequent events recorded after their occurrences (Sorted by number of delayed recordings).

Event Type (number of delayed recordings)	Average Delay (minutes)	Median Delay (minutes)	% of Events with delay
Charting Complete (225,651)	0.51	0.50	81.6%
Patient departed (134,388)	34.58	9.77	99.8%
Patient arrived in ED (134,377)	2.59	1.97	99.8%
Patient discharged (123,530)	33.90	11.43	99.4%
Nurse/tech Assigned (103,696)	0.50	0.50	59.3%

Discussion

Results indicated delays in recording majority of the five frequent ED activities in the EHR by the computers and clinicians. Delayed recording can be due to fast pace of work in EDs, in which treatment outweighs documentation at the time it occurs. Researchers should consider these delays to ensure that event sequences are captured accurately when using EHR systems as a data source. Supporting EHR data with radio-frequency identification technology, which captures real-time data on clinicians' activities, can enhance the quality of the data for workflow research.

Automating Extraction and Calculation of Daily Dose and Duration for Medications in EHRs

Jennifer A. Pacheco[1], William K. Thompson, PhD[1], Kathryn L. Jackson, MS[1], Abel N. Kho MD, MS[1]

[1]Feinberg School of Medicine, Northwestern University, Chicago, IL

Abstract

As part of the eMERGE (electronic Medical Records and Genomics) project, we are engaged in studies that require the extraction of medication data from EHRs (Electronic Health Records). In order to calculate daily dose and duration of medications, we found it necessary to supplement the existing NLP (Natural Language Processing) tool we are using with additional techniques. The result is an open-source workflow that can be readily re-targeted to multiple medications and is 90% accurate.

Introduction

Increasingly in clinical research, and especially in pharmacogenetic studies[1], it is important to extract and calculate numerical dose and duration for medication usage from EHRs. Current NLP applications such as MedEx produce results which are often not numeric nor measured in consistent units. At least one study has extracted such data by extending and supplementing tools such as MedEx, but only for 1 specific medication[1].

Methods and Materials

We created an executable workflow in KNIME (Konstanz Information Miner, knime.org) for calculating average daily dose and duration for medications, which extracts the numerical data needed for the calculations in 3 major steps: 1) combining the results of the MedEx NLP tool on prescription order signature line text with discrete medication data from our EHR where available, both of which are mostly non-numeric; 2) using pattern matching (RegEx), Java, and other data transformation tasks in KNIME, to convert dose and duration into numeric fields in standardized units; and 3) applying logical rules, for duration in particular, prioritizing fields to determine an accurate daily dose and duration.

We tested our algorithm on statins and metformin, from which a random representative subset of 20 patients' 100 medications records were selected for manual review in order to compute accuracy statistics. The review was done by reviewing medication records, discharge summaries, and encounter notes, in both inpatient and outpatient EHR systems (Cerner for inpatient and Epic for outpatient), by JAP, who is an experienced biomedical informaticist.

Results

Ninety percent of the medication records from the KNIME workflow were accurate when compared to the medication records found during manual review. Many if not most of the errors were due to the NLP algorithm not finding a given data point needed to calculate daily dose or duration, i.e. missing data such as 22% of dose frequency missing. We are making our KNIME workflow publicly and freely available at http://bit.ly/1nowjqt.

Discussion and Conclusion

This work builds on existing work but expands to include multiple medications and is tested on 2 different commercially available EHR systems. Future work includes expanding to more types of medications, i.e. more than just orally administered medications measured in mg, and using algorithms to fill in missing data (with most frequently prescribed dose frequency for a given medication for example).

Problem-Solving Methods for Public Health Informatics Practice and Training: Insights from Technical Assistance Projects

Sridhar R. Papagari Sangareddy, MS[1], Laura Franzke, MPH, PhD[1], Herman Tolentino, MD[1]

[1] Centers for Disease Control and Prevention, Atlanta, GA

Abstract

A core component of the Centers for Disease Control and Prevention's Public Health Informatics Fellowship Program (PHIFP) is the Info-Aid — a short-term technical assistance project that PHIFP fellows lead to solve public health informatics (PHI) problems for public health agencies. Info-Aids are used in a range of PHI problems and require different problem-solving methods (PSMs). A taxonomy for classifying PSMs for PHI is presented that is based on a problem-solving framework and systems concepts.

Description

PHI is the systematic application of the knowledge of systems that capture, manage, analyze, and use information for improving population health. PHI practice involves problem solving, which requires the systematic application of PSMs. PHI PSMs are not well-documented in literature. In Info-Aids, PHIFP fellows are engaged in real-world PHI problem solving for various PHI problems. To solve them, fellows adapt and adopt PSMs from referent disciplines (e.g., computer science, information science, or the social sciences). Using lessons learned from Info-Aids, we analyzed and then synthesized these methods into a taxonomy (Table 1) that can be the basis of reasoning steps and knowledge types needed to solve problems.[1] This taxonomy can serve as a resource for fellows to classify and organize PSMs they need to apply in a given Info-Aid; the taxonomy also can be useful for other PHI training programs. The taxonomy can be further refined and validated to identify PHI problems in practice.

Table 1. A Preview of Taxonomy of PSMs Based on Information System Structure, Function, and Process

Problem-solving method		SWOT[b] analysis	Data modeling	Record linkage
Problem space related to public health information systems[a]	**Structure**	Organization	Data	Information
	Function	Assess	Capture	Manage
	Process	Planning	Design	Development
Problem-solving goal		Strategic planning	Database design	Integration of data from different sources

[a] *Structure* defines dimensions of an information system, as represented by Richard Heeks' Onion Ring model (Source: Heeks R, Bathnagar S. Understanding success and failure in information age reform. In: Heeks R, ed. Reinventing Government in the Information Age: International Practice in IT-Enabled Public Sector Reform. Abingdon, Oxon: Routledge; 1999: 49–74.); *function* defines the steps in generating value from an information system (Source: Taylor RS. Value-added processes in the information life cycle. Journal of the American Society for Information Science 1982:33:341–6); and *process* explicitly defines the phases of an information system implementation.

[b] SWOT = strengths, weaknesses, opportunities, and threats.

Network Analysis of Common Eligibility Criteria in Cancer Clinical Trials

Chin S. Park[1], MBA, RN; Jacqueline A. Merrill[1, 2], PhD, MPH, RN; Chunhua Weng[2], PhD
[1]School of Nursing, [2]Department of Biomedical Informatics
Columbia University, New York, NY

Abstract

To understand the patterns in eligibility criteria across different cancer types, we performed a network analysis of frequent eligibility criteria for 124 cancer types available on ClinicalTrials.gov. Free text eligibility criteria were extracted using natural language processing. The results indicate that substantial eligibility criteria were shared across various cancer clinical trials. The findings have implications for knowledge reuse in clinical trial designs.

Introduction

Eligibility criteria are specifications written by clinical researchers regarding who would qualify for a clinical study. We hypothesize that a study of eligibility criteria patterns in the cancer clinical trial research community can help us identify systematic knowledge for subject selection for cancer research. This study aims to identify which patient characteristics are frequently shared among cancer clinical trials, within and across cancer types.

Methods

Cancer clinical trial summaries for 124 cancer types archived between years 1999-2013 were extracted from ClinicalTrials.gov. An unsupervised text mining method was utilized to identify frequent eligibility criteria from all these studies [1]. Each eligibility criterion had information about its prevalence, e.g., 50% indicates that a criterion appeared in 50% of all cancer trials of a selected cancer type. The frequency information was converted to a corresponding rank, as shown in Table 1. Network analysis and visualizations were accomplished using ORA-NetScenes. The nodes indicate cancer types (green) or frequent eligibility criteria (red), which were eligibility concepts such as "anemia" or "concurrent malignant neoplasms". The links indicate the associations between cancer types and eligibility concepts.

Table 1. Common Eligibility Criteria (CEC) frequency of appearance converted to corresponding rank.

CEC Frequency	Rank
90% - 100%	10
80% - 89%	9
70% - 79%	8
60% - 69%	7
50% - 59%	6
40% - 49%	5
30% - 39%	4
20% - 29%	3
10% - 19%	2
< 10%	1

Figure 1A. Network of 124 cancer types linked to 11,195 CECs.

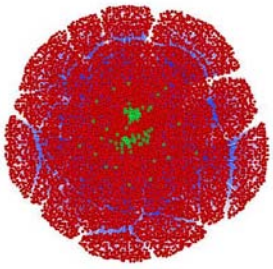

Figure 1B. Network of 62 cancer types linked to 22 CECs.

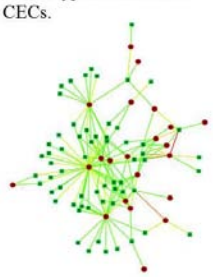

Results

We identified 11,195 unique frequent eligibility criteria, and the resulting network presented 81,145 links out of 1,388,180 possible links, indicating a network density of 5.8% (Figure 1A). When the criteria were filtered by those only ranked 6 or higher, only 22 were linked to 62 cancer types (Figure 1B). Degree centrality measures were calculated for the complete network of 124 cancer types and 11,195 criteria. The cancer node with the highest in-degree centrality (number of links from other criteria) was "leukemia erythroblastic acute," and the criteria node with the highest out-degree centrality (number of links to other criteria) was "therapeutic radiology procedure." The top 25 nodes for both in-degree and out-degree centrality were identified and listed in decreasing order by rank.

Discussion

The centrality measurements indicated that criteria such as "therapeutic radiology procedure" and "disease characteristic" are nodes with high out degree centrality and therefore linked to more cancer types than the other criteria. This concurs with published cancer research literature and demonstrates face validity of the results. Also, this network analysis found only 22 of 11,195 unique criteria were linked to half of 124 cancer types when looking for criteria that appear in 50% or more of the research trials. The patterns revealed by the network analysis suggest that certain criteria are common links across different types of cancers. Continued work in identifying central criteria of eligibility criteria may help indicate the types of patient information that are important to collect in electronic health record (EHR) systems in order to facilitate electronic eligibility screening for cancer clinical trials.

Clinical Data Modeling EHR Data for Understanding Factors Related to Hospital-acquired Catheter-Associated Urinary Tract Infection (CAUTI)

Jung In Park, BS, RN[1]; Steven G. Johnson, MS[2]; Matthew D. Byrne, PhD, RN[3]; Beverly Christie, DNP, RN[4]; Lisiane Pruinelli, MS, RN; Suzan Sherman, PhD, RN[4]; Bonnie L. Westra, PhD, RN, FAAN, FACMI[1]

[1]University of Minnesota, School of Nursing; [2]University of Minnesota, Institute for Health Informatics; [3]St. Catherine's University; [4]Fairview Health System

Problem

The purpose of this study was to create a clinical data model that includes normalized and standardized data from an academic health center clinical data repository (CDR) as a preliminary step for knowledge discovery research planned in a subsequent study.

Introduction and Background

Catheter-Associated Urinary Tract Infections (CAUTIs) are the most common type of infection in hospital, accounting for 40% of all nosocomial infections per year. The Centers for Medicare and Medicaid Services (CMS) announced hospital acquired Urinary Tract Infections (UTIs) as one of eight conditions for which hospitals will not receive additional reimbursement. Studies identifying risk factors and evidence-based guidelines for CAUTIs exist, but the occurrence rates are still high. There is a clear need for further understanding of either additional factors and/or subgroups of patients to understand predictors associated with hospital-acquired CAUTI to reduce the occurrence rates. With the implementation of electronic health records (EHRs), it becomes possible to conduct research using large data sets to gain new insights into which patients benefit the most from different approaches to prevention of CAUTI.

Methods and Data Source

The University of Minnesota developed a CDR which includes more than two million patient and multiple data types (demographics, encounters, diagnoses, procedures, medications, and lab values) for ambulatory and hospital data. Additionally it includes flowsheet data which contain documentation of essential data for assessment and prevention of CAUTI. A data set from the CDR was evaluated and compared with the literature to create a data model to discover patient characteristics and interventions by subgroups of patients that can provide new insights to reduce infections.

Results/ Discussion

A clinical data model from EHR data for CAUTI will be presented. It was created from patients' health records in the CDR for patients hospitalized between 10/1/10 and 12/31/2013. Data normalization and standardization will be discussed. In a future study, data mining techniques will be employed to discover patterns of patient characteristics and provider interventions within subgroups of patients to gain new insights for reducing the rates of hospital-acquired CAUTI.

Automatic Engine for Mapping Mycobacteriology Reports to SNOMED-CT

Olga V. Patterson, PhD[1,2], Scott D. Nelson, PharmD[1,2], Makoto M. Jones, MD[1,2], Kimberly Findley, RN[3], Kevin L. Winthrop, MD, MPH[4], Kevin P. Fennelly, MD, MPH[3,5], Scott L. DuVall, PhD[1,2]

[1] VA Salt Lake City Health Care System; [2]University of Utah, Salt Lake City, UT; [3]Office of Public Health, Veterans Health Administration, Gainesville, FL; [4]Oregon Health and Science University, Portland, OR; [5]University of Florida, Gainesville, FL

Background

The genus *Mycobacterium* contains a number of pathogens of public health significance that cause infections ranging from tuberculosis and leprosy to debilitating infections in individuals with structural lung disease. Since administrative codes underreport mycobacterial infections, coded microbiology data are necessary to gain a complete picture of the burden of disease. Detection of mycobacteria is performed in the laboratory using a combination of culture and molecular methods. The generation of coded data from microbiology reports in large population, such as in the US Department of Veterans Affairs (VA), requires the development of an innovative strategy for data extraction. Previous research efforts involved contacting individual laboratories, collecting data directly from sources, and aggregating results across multiple laboratories.[1] This approach is time intensive and, without incorporating other information from the medical record, only allows analysis of trends and distribution of positive tests. Generating coded microbiology is challenging because of insufficient interoperability of laboratory systems and clinical patient record, especially in cases when an outside lab performs mycobacterial cultures. Typically, the test results are passed to the requesting organization as text reports. We developed a natural language processing (NLP) system to identify mentions of mycobacteria in lab reports, map the mentioned organisms to SNOMED-CT codes, and extract test outcomes.

Methods

A corpus of 528,083 laboratory reports from 128 VA stations from 2008 to 2012 was split into 3 parts – half of the notes for training, a quarter for development testing, and a quarter for final validation. Four clinical annotators manually reviewed 11,200 lab reports randomly selected from the training subset to identify mentions of mycobacteria and relevant test results. A dictionary was developed using these annotations that was manually mapped to appropriate SNOMED-CT codes. Text indicating positive, negative, and unknown test results was transformed into co-occurrence patterns. An NLP system was built using a set of libraries that facilitate rapid creation and deployment of high throughput, parallel NLP systems.[2,3] Term identification, mapping to SNOMED-CT codes, and test outcomes were implemented using regular expressions for each of the targeted organisms. Rules were developed to determine the final test result in cases with multiple mentions of the same organism in the same document.

Results

System performance was evaluated using 5,400 documents selected from the validation subset. Extracted test results from each documents processed by the NLP system were reviewed by two clinical annotators. Document-level classification accuracy was 0.95 for positive test results and 0.942 for negative test results.

Conclusion

Automatic detection of positive laboratory test results using NLP with mapping to a controlled terminology can detect mentions of mycobacteria, and may help with real-time surveillance of Veterans with mycobacterial infections.

Kidney transplantation web portal for the citizens in Brazil

Alissa Peres Penteado, MSc Fellow[a], Frederico Molina Cohrs, MSc, Rafael Fábio Maciel, MD MSc[b], Bartira de Aguiar Roza, PhD Associate Professor[a], Cristina Lúcia Feijó Ortolani, PhD Full Professor[c,a], Ivan Torres Pisa, PhD Associate Professor[a]

[a] *Universidade Federal de São Paulo UNIFESP, Brazil* [b] *Instituto Social de Assistência a Saúde, Caruaru, Brazil* [c] *Universidade Paulista UNIP, São Paulo, Brazil*

Abstract

The kidney transplantation process in Brazil is based on laws, decrees, ordinances, and resolutions, and it's unique for all the country. It's a complex process for non-specialized healthcare professionals, non-specialized healthcare managers, and citizens. This paper presents our effort to model this organizational process using business process modeling notation considering it a simple language and to model a web portal to support this process, legislation repository, and news about transplants in Brazil.

Introduction

The kidney transplantation process in Brazil is defined through laws, decrees, ordinances, and resolutions (1), but there is no defined theoretical map describing the entire process. Business process modeling notation (BPMN) (2) has been used to represent actions in organizations, aiming to increase efficiency, quality, and maturity (3). Taking it into consideration we decided to create a diagram that can represent the flow of this entire process. In order to make this process public available for the Brazilian citizens we will design a web portal including graph representation, a legislation repository, and news about transplant in an easy and dynamic way. This study took into consideration just the kidney transplantation, because Brazil has good global indices in this type of transplant in absolute numbers (4). But when it comes per million population (pmp) rate, Brazil is only the 33th in the world rankings. This is the reason why we decided to analyze this process and try to describe why this process is too complex, its barriers and modification possibilities.

Methods

For the creation of the kidney transplantation process the approach taken was an exploratory observational study with analysis on documents and processes (5). We identified and gathered official digital documents (laws, decrees, and ordinances) relating to the kidney transplantation process in Brazil (26 regional states plus Distrito Federal) and we analyzed them using process analysis methodology (5). Then a kidney transplantation process in Brazil based on BPMN was created using Bizagi version 2.4.0.8 (bizagi.com). We conduct 2 different evaluation tasks to ensure that the process was properly represented. The first evaluation was using Delphi methodology with 4 specialists in kidney transplantation field. The second evaluation was a survey application with 27 specialists (one from each state from Brazil plus Distrito Federal) in the kidney transplantation field as well. In order to make the process created available for the Brazilians citizens, a web portal is under construction. We have been using PHP language and MySQL database considering web and mobile access. In this the non-specialized healthcare professionals, non-specialized healthcare managers, and citizens from Brazil will find in an easy and dynamic way the process in a graph representation, a legislation repository, information about healthcare provider, and news about transplant.

Results

The main result is the kidney transplantation process in Brazil represented in BPMN available at telemedicina6.unifesp.br/projeto/kidneytransplant/amia2014. We analyzed 18 digital documents that resulted in a process with 40 activities and events, 6 organizations involved and 6 different stages. In consequence a web portal that makes this work public available for the Brazilians citizens is under construction. The web portal will be available at transplante.info in November 2014.

Conclusion

A representation of the kidney transplantation process in Brazil was created using BPMN, which can be read and interpreted by the professionals involved in this process. In add, with the future availability of this process in a web portal, Brazilian citizens must understand it easily. We acknowledge CAPES for scholarship financial support.

Toward a Conceptual Understanding of Social Network Analysis in Public Health Derived from Published Literature

Catherine Pepper, MLIS, MPH, Juliana J. Brixey, PhD, MPH, MSN, RN
School of Biomedical Informatics, UTHealth, Houston, TX

Abstract

Social network analysis (SNA) is an empirical research method used in public health to evaluate organizational effectiveness in collaboration and knowledge flow [1]. Content analysis of articles from a systematic literature review resulted in a concept map that visualized intersecting components of SNA and the public health system. SNA provides a theoretical and scientific basis for describing public health network structures, and the concept map suggests a linkage between "SNA" and "public health information systems."

Introduction

Social network analysis (SNA) is an empirical research method that can graphically model "the mapping and measuring of relationships and flows between people, groups, organizations, computers, or other information/ knowledge processing entities."[1] SNA has been used in public health to describe organizational collaboration and information flows[1], but a conceptual basis to inform these studies has yet to be articulated. Whereas previous systematic reviews of the literature have examined SNA in disciplines such as the social sciences, business, and healthcare[2], this conceptual analysis identifies SNA studies in the context of public health organizations and maps linkages between network measures and components of the public health system. The aim is to derive a conceptual understanding of social network analysis and public health information systems.

Methods

A systematic literature review was conducted to retrieve published research on the application of social network analysis in public health. Content analysis of retrieved articles was performed: first, to identify the conceptual components of SNA and of the public health system by extracting keywords and indexing terms; then, to categorize articles according to study design, network measures used, and data collection and analysis methods. Concept mapping is an accepted method to link concepts in the literature[3]. A concept map was constructed by extracting and relating the main ideas from individual articles, with derived linkages between SNA and the public health system.

Results

The literature searches yielded a study set of 34 articles, with an additional two articles that provided background. Content analysis of these articles identified a variety of study designs, including qualitative, cohort, mixed-methods, experimental designs, and descriptive analyses. Network measures included centrality, density, and socio-spatial. Data analyses included network analyses and sociograms of various variables, including information sharing and collaboration. These elements were depicted in a concept map that provided a visualization of intersecting components of SNA and the public health system.

Discussion

Both SNA and the public health system are displayed in a concept map as complex, multi-layered domains. Two primary targets of SNA investigations emerged from this review: Information diffusion/distribution and coordination/performance of public health systems as measured by organizational collaborations. Results show that SNA provides a theoretical and scientific basis for describing the complexity of the public health system, and the concept map suggests a linkage between "social network analysis" and "public health information systems."

Conclusion

The concepts of social network analysis and the public health system intersect at key points. SNA has been used to describe and analyze the structure and components of the public health system. Disease surveillance systems, a sub-set of the public health system, may be viewed as social networks, thereby candidates for SNA. Further research will focus on defining optimal social network structure for performance of public health surveillance systems.

Categorizing RxNorm Concepts by Treatment Intent

Pascal B Pfiffner[1], Joshua C Mandel[1], and Kenneth D Mandl[1,2]

[1]*Boston Childrens Hospital Informatics Program at Harvard-MIT Health Sciences and Technology, Boston, MA*
[2]*Center for Biomedical Informatics, Harvard Medical School, Boston, MA*

Introduction & Background

For research and user facing applications alike, categorizing drug products by treatment intent is a desirable goal. National Library of Medicine's (NLM) RxNorm terminology does not yet explicitly categorize drugs on the RxNorm concept id (RXCUI) level. However the National Drug File - Reference Terminology (NDF-RT), produced by Veterans Affairs (VA), is distributed alongside RxNorm and provides additional drug information. This presents two interesting approaches to categorizing RxNorm concepts:

Therapeutic Intent & Contraindication provides treatment intent via a `may_treat` relationship for a range of drugs and ingredients. This allows to arrive at drug-level therapeutic intents by looking at a medication's ingredients.

VA Drug Classification classifies drugs, primarily of the "clinical drug"-type concepts (`TTY=[S]CD`) and allows to infer therapeutic intents by looking at a drug's class. Different RxNorm concept types (e.g. branded drug forms, `TTY=SBD`) are not explicitly linked to a drug class, however their class can be deduced by walking RxNorm relationships.

Previous work has determined that NDF-RT covers about 46% of "semantic clinical drug" (`SCD`) type RxNorm concepts (Pathak and Chute, 2010). We were interested whether combining our two approaches would complement each other and cover a higher percentage of drug-type RxNorm concepts, not limited to `SCD`. Having access to treatment intents for e.g. branded drug concepts is useful for patient-facing apps where a patient might know the drug by brand name.

Materials & Methods

RxNorm 1/6/2014 Full Update Release was downloaded from nlm.nih.gov on January 20, 2014. Data was imported into an SQLite database and our lookup algorithms were applied using Python scripts, available from github.com/chb/py-umls, as follows:

RxNorm concepts of `SCD*`, `SBD*`, `*IN`, `BN` and `*PCK` types were retrieved from the database. Each concept's ingredients (`TTY=IN`) were determined by recursively looking up relationships in the `RXNREL` table. Related treatment intents of these ingredients could then be looked up in the `RXNCONSO` table and assigned to the original RXCUI.

A table was created to store known mappings between concepts and VA drug class, as defined in the `RXNCONSO` table. Heuristically defined, immediate relationships of these known concepts—e.g. `tradename_of` for `SBD` to arrive at an `SCD` with known drug class—were then looked up and the same drug class was assigned to these concepts and stored. This process was repeated 5 times, each time looking at relationships for newly mapped concepts.

Results

Of the 203,175 RxNorm concepts, 72% (146,213) were assigned one or more treatment intents, 71% (143,263) were assigned one or more VA drug classes and 80% (163,339) were assigned at least one of the two. While we have yet to qualitatively analyze these assignments, exploratory analyses suggest that results from both approaches are well aligned and complementary. An (shortened) example concept of `SBDF` type is shown in figure 1.

```

Figure 1: Example JSON document for a branded drug form (RXCUI 364073, TTY `SBDF`) with drug class and appropriate treatment intents. The "label" and "treatmentIntents" properties were shortened to fit one page.

Conclusions

Depending on use-case, having quick access to either treatment intents or drug class—and in many cases both—might prove useful for a range of medication related computational tasks, not least in view of patient-centered outcomes research with patients managing their medications.

Meaningful Use & EHR Scope

Valerie J. H. Powell, MS, PhD, RT(R)[1], Amit Acharya, BDS, MS, PhD[2], Robert H. Posteraro, MD, MBI, FACR[3], Thankam Paul Thyvalikakath, DMD, MDS, PhD[4,5]
[1]Robert Morris University, Moon Township, PA; [2]Marshfield Clinic Research Foundation, Marshfield, WI, [3]Health Sciences Center, Texas Tech University, Lubbock, TX, [4]School of Dentistry, Indiana University (IUPUI), Indianapolis, IN, & [5]Regenstreif Institute, Inc., Indianapolis, IN

Abstract
Assuring that the scope of the electronic health record (EHR) includes the entire human body (the stomatognathic system along with the "rest of the body") would contribute to advancing the goals of Meaningful Use (MU).

Introduction
MU is defined as using certified EHR technology in order to improve quality, safety, efficiency, & reduce health disparities, engage patients & family, improve care coordination, & population & public health, as well as to maintain privacy & security of patient health information. The scope of the EHR is often bounded by the traditional separation of the scope of health care into medical & dental categories & therefore does not necessarily include the dental portion of the patient's record. However, microbes & disease processes are under no obligation to respect any division of health care delivery/research & patient records into medical & dental silos. If we examine MU, we find among the core measures, CMS69v1, NQF 0421, Preventive Care & Screening: Body Mass Index (BMI) Screening & Follow-Up. Evidence reveals relationships on BMI & obesity with two oral chronic conditions, caries & periodontal disease.[1,2,3] Another core measure is CMS68v1, NQF 0419, Documentation of Current Medications in the Medical Record. Because, as detailed in Powell et al., eds.,[4] a given patient can receive concurrent medical & dental care, including surgery & prescriptions from the dental provider, documentation of current medication requires listing medications that are in the patient's dental record to be complete. Yet another core measure is: CMS90v1, Functional status assessment for complex chronic conditions. As long as the separation of scopes of medical & dental care & their respective patient records systems persist, neither the common systemic nor the oral health chronic conditions can be adequately addressed through separated streams of care. Extensive clinical literature, for example, documents the interrelationships between periodontal disease & diabetes mellitus. Examining Löe[5] reveals how well-established the understanding of this connection is. To respond to the report of Chaffee et al.[6] to improve care safety & quality would require availability of the maternal dental record during the prenatal period in order to prevent caries & early childhood caries (ECC) in the newborn. To improve quality & safety for patients, in view of the implications of the research of Rubinstein et al.[7], revealing a connection between a common oral microbe & colorectal cancer, requires integrated medical & dental care & patient records. A decision as to how to prioritize categories of patients who care would benefit in quality & safety from an EHR scope that explicitly includes oral health data can be made utilizing the 30 plus contact points discussed in Powell et al. eds[4].

Conclusion
Evidence indicates that MU objectives & core measures would be served by assuring that the scope of the EHR includes the stomatognathic system & associated structures, as well as the remaining systems of the body. Therefore we propose that the scope of the EHR for purposes of MU be established as the entire human body.

Temporomandibular Disorder Treatment Adherence Improved By A Mobile SMS-Based Intervention

Cristiana S. Prado, MSc Fellow[1], Frederico M. Cohrs, PhD Fellow[1], Cristina L. F. Ortolani, PhD, Full Professor1,[2], Evandro E. S. Ruiz, PHD, Associate Professor[3], Ivan T. Pisa, PhD, Associate Professor[1]

Abstract

The use of mobile phone short message service (SMS) leaveraging follow-up therapy has been studied in various areas of health care. We present a research aimed to assess the effects this messaging media as intervention technique on temporomandibular disorder (TMD) treatment adherence during by a randomized controlled trial.

Introduction

The TMD refers to a set of conditions that occur in the orofacial region that compromise the comfort and normal functioning of the hard and soft tissues of the masticatory system[1]. Literature presents positive results in researches using SMS reminders via cellphone to improve patients' adherence to treatments of different kinds of diseases[2].

Methods

The development of web system used in this study, DTM Alert System, is based on an existing model[3]. A randomized controlled trial was conducted at the TMD and orofacial pain outpatient clinic at Universidade Federal de São Paulo (UNIFESP). The population consisted of 38 patients, selected according to inclusion and exclusion criteria and allocated randomly into two groups. The control group (n=19) received standard treatment and the intervention group (n=19) received standard treatment plus SMS reminders. Each patient was followed up for three months and adherence was measured by assessing the patient`s clinical evolution through objective variables (vertical extent of mouth opening, right, left maximum bite force) and visual analog pain scale (VAS) subjective variable. Non-attendance related to follow-up visits and satisfaction questionnaires regarding the delivery and outpatient care were also assessed. This study was approved by Brazilian Ethics Committee SISNEP (# 2135/11).

Results

The DTM Alert System was tested and approved as a project platform for inpatient SMS communication. The tests included message delivery likelihood, system usability and messages content analysis. A descriptive data analysis was carried out. The mouth opening average values, maximum bite force and VAS in the intervention group had a better average when compared to the control group (12% vs. 6%; 11% vs. -12%; 78% vs. 46% improvement respectively). The percentage of control group non-attendance was 22%, while the percentage of the intervention group non-attendance was 11%. The responses to the satisfaction survey were positive.

Conclusion

The system was considered useful and feasible for use in the outpatient clinic where the research was carried out. The results related to the clinic evolution variables and non-attendance suggest that the support offered by SMS reminders had a positive impact in the TMD symptoms and adherence to treatment.

Abstract

The use of data mining techniques for analyzing data sets from electronic health records (EHR), and evaluating and expanding evidence based practice (EBP) guidelines requires new approaches. Mining patterns of care for sub-populations over a period of time enables the discovery of best practices for diabetic patients with health disparities and strengthens the content and appication of EBP for clinical decision support.

Introduction

The use of multidisciplinary scientific EBP guidelines during hospitalization can assist diabetic patients to regain their health and thus reduce rehospitalization. Our research reuses EHR data to address new research questions that explore patterns of patients characteristics and resources, EBP interventions, and health impovement. To acomplish these goals, we develop approaches for feature extraction from an EHR to characterize the patient's state at hospital admission and track their progression over time. This analysis will identify the factors (interventions or other aspects of the patient's health status or social determinants) that contribute to successful and unsuccessful outcomes for the patients with diabetes. The interventions both medical and nursing guidelines as well as discovering data derived evidence (DDE). This study aims to describe a methodology for assessing the value of the EBP guidelines and finding DDEs for subgroups of patients, particularly for those with health disparities.

Methods

After IRB approval, data were extracted from a clinical data repository (CDR) at the UMN. The CDR contains more than 2 million patients from 8 hospitals and 40 clinicals using the same EHR. Our de-identified dataset included patients hospitalized between 1/1/09 and 12/31/13 with a primary or secondary diagnosis of diabetes and their follow up for at least 2 years. Data included : social and demographics, diagnoses, vitals, labs, procedures, medications and flowsheets.

One part of this research involves analysis of complications of diabetes: cardiovascular and peripheral vascular diseases, nephropathy, retinopathy, neuropathy, and ultimately death. Different sets of comorbid conditions have different risks for outcomes. Survival association techniques using the Cox-proportional hazards model with Martingale residuals and Association rule mining can be used to detect interactions between co-morbid conditions and risk factors.

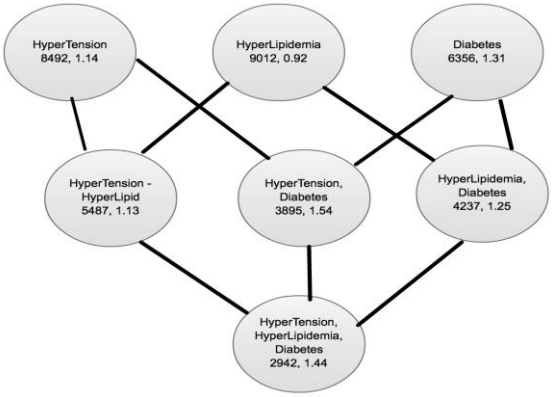

Figure 1: Diagram with sample size and relative risk of mortality for each condition.

Results/Conclusion

In the figure, we present the sample size and relative risk of mortality for diabetes related disease progression. We can observe how the relative risk increases significantly when the patient has hypertension and diabetes, as compared to when the patient is diagnosed with hypertension and hyperlipidemia.

[4] Group Health Research Institute

Abstract / Background. *The Strategies and Opportunities to Stop Colorectal Cancer (STOP CRC) study is a collaboration between a health informatics system, clinic networks, and research institutions. The study will assess the reach and effectiveness of an intervention program using electronic health record (EHR) clinical decision support (CDS) tools to improve rates of colorectal-cancer screening in federally qualified health centers (FQHCs). Few studies, and no large studies, aimed at raising CRC screening rates have utilized an EHR-embedded system. Our study strives to automate CRC screening to as great a degree as possible, thus improving clinical efficiencies and patient outcomes. However access to comprehensive clinical data varies in completeness and quality in an "open" health care network, which led to implementation challenges.*

Methods: Selecting patients for automated CRC screening intervention depends on access to data regarding previous such screening done on patients to determine if they are due for another screening: data pertaining to inclusion criteria (patient age, PCP assignment, provider type, viable mailing address, and visit in past 12 months), and data pertaining to exclusion criteria (e.g., known conditions and diagnoses such as colorectal disease, and previous screening). We examined multiple sources of data within the EHR as well as outside sources to find patients eligible for automated screening. Chart audits were performed to validate inclusion and exclusion processes.

Results: We created processes for identifying patients due for CRC screening, but with caveats and compromises on ideal data availability. With multiple lab interfaces processing fecal occult blood tests, multiple outside sources of colonoscopy results, and systemic barriers to indigent patients receiving recommended care came challenges that had to be surmounted or taken into account. Our findings from the initial validation work led to restrictions on the exclusion criteria to cast a wider net over patients in need of screening. This led to instituting new clinical workflows and data collection tools to improve future patient selection methods and, as a result, improve screening rates.

Discussion: In an ideal world, all patients would receive necessary CRC screening, and all such data would be available to clinicians and researchers. This is not the case. We will discuss (a) barriers to adequate patient care, (b) problems with data availability and quality, and (c) methods for working around and improving these issues.

Learning Objective: Attendees will be able to formulate an approach to the design and implementation of a population-based intervention requiring integration of lab, procedure, and other clinical data.

Examining the Potential for CPOE System Design and Functionality to Contribute to Medication Errors

Arbor J.L. Quist[1], Alexandra Robertson[1], Thu-Trang Thach, MPH[1], Lynn Volk, MHS[2], Adam Wright, PhD[1,2], Shobha Phansalkar, RPh, PhD[1,3], Sarah Slight, PhD[1,4], David W. Bates, MD[1,5], Gordon D. Schiff, MD[1,5].

Abstract

To understand how the design of computerized prescriber order entry (CPOE) systems can facilitate medication errors, we collected functionality data from 10 different CPOE systems and examined software team support reports. We found that inconsistencies in CPOE functionality, confusing design, and lack of standardization contribute to medication errors and user frustration.

Background

The Institute of Medicine has estimated that more than 1.5 million people are harmed by medication errors each year; thus, reducing medication errors is essential in improving patient safety[1].While CPOE systems reduce medication errors by using effective clinical decision support (CDS) and creating legible prescriptions, they can also introduce new types of errors[2]. Inflexible ordering screens, inability of information systems to communicate, and prescribers relying on often inaccurate CPOE dose displays are examples of ways that CPOE systems can facilitate medication errors[3]. The Brigham and Women's Hospital (BWH) CPOE Medication Safety (CPOEMS) Project was funded by the FDA to better understand the functionality, features, and interfaces of 10 CPOE systems and how they may contribute to errors.

Methods

We studied 10 CPOE systems that varied in providers, vendors, and care settings across 6 different healthcare facilities. We collected CPOE functionality data through both usability testing and detailed interviews with 35 CPOE system users and IT specialists at each site. We created test patients in each system and developed a CPOE Medication Safety Assessment Tool to assist in collecting standardized information on the systems, including details on drug name presentation, alerts, and system history. These interviews and system evaluations were then recorded, transcribed, and organized to highlight the similarities and differences between functionality in the systems. Finally, we reviewed integrated software team reports to understand how CPOE issues lead to medication errors.

Results

We found a large number of inconsistencies within and across systems, including confusing CDS and system specific issues that could cause medication errors. For example, one site's inpatient and outpatient systems fire different alerts for the same drug, causing confusion in medication profiles. A review of integrated software team reports in one outpatient system revealed that alerts fire only when medications are prescribed anew, and not when re-ordered. We also observed variation in ways that medications are discontinued. One system allows, but does not require, a discontinuation reason while another requires the user to choose one of 10 reasons for discontinuation.

Conclusion

We developed a better understanding of CPOE functionality by examining error reports, usability assessments, and vulnerability testing. This analysis helps us to conclude that CPOE system functionality can be improved to prevent frustrations and confusion errors through more standardized and less confusing interfaces and design features.

With Whom Will I Share?
A Quantitative Data Analysis of the Special Project of National Significance Survey for Persons Living with HIV/AIDS.

S. Raquel Ramos, MSN, RN, MBA, Peter Gordon, MD, Suzanne Bakken, RN, PhD
Columbia University Medical Center, New York, NY

Abstract

Health information exchange (HIE) is utilized nationally. However in New York State (NYS), HIE participation is under appreciated and potentially more so from those living with chronic illness, such as HIV. The purpose of this study was to quantitatively explore factors associated with persons living with HIV (PLWH) willingness to share all of their personal medical data electronically with specific types of healthcare personnel.

Introduction

Patient tracking, linkage and retention in care have been empowered through health information technology (HIT) innovations, such as HIE. HIE allows clinicians to access pertinent up-to-date health information that could potentially save lives, yet it may be underutilized in NYS by PLWH. Moreover, it has the potential to strengthen patient self-agency[1], patient care and outcomes in the midst of HIV stigma, fear and discrimination. As a chronic illness with over 1 million persons infected, HIV has been associated with co-morbid conditions that affect the cardiovascular, hepatic and endocrine systems. Therefore it is imperative that continuity of care be facilitated through the HIE. Thus, we sought to use quantitative methods to explore what factors were associated with PLWH willingness to share all medical data electronically with specific types of healthcare personnel.

Methods

A survey from the Special Projects of National Significance (SPNS) was completed by PLWH (N=291) participating in a Medicaid Special Needs Plan for PLWH in New York City. Independent variables selected for analysis were: age, gender, income, education, being US born, ethnicity and sexual orientation. The dependent variables were sharing all personal medical data electronically with specific healthcare clinicians including specialists. Descriptive statistics and non-parametric techniques were performed to select variables for the logistic regression using SPSS v21[2]. A binary logistic regression was performed and the Bonferroni correction[3] was applied for the multiple dependent variables; p – value = 0.0125 was used as the alpha for significance.

Results

No independent variables significantly influenced a PLWH willingness to share all of their personal medical data electronically with their PCP or other clinicians. However, being US born significantly influenced PLWH willingness to share all personal medical data electronically with other health providers (OR=3.083, CI=1.633-5.810) and with non-HIV specialists (OR= 2.504, CI = 1.32-4.569). Persons that are US born are three times more likely to share all of their personal medical data electronically with other health providers (ER/Hosp personnel) and non-HIV specialists (cardiologists/OBGYN) than those who are not US born.

Conclusions

With the expansion of HIE in healthcare, further insights are warranted to better understand what specific cultural factors influence HIV- positive non-US born person's willingness to share all of their medical data electronically.

Evaluation of Existing Phenotype Authoring Tools for Clinical Research

Luke V. Rasmussen[1]; Jie Xu, MS[1], Ruijue Liu[2], Qian Zhu, PhD[3], Jennifer A. Pacheco[1], Jyotishman Pathak, PhD[3], William K. Thompson, PhD[4], Joshua C. Denny, MD, MS[5], Huan Mo, MD, MS[5], Richard C. Kiefer[3], Peter Speltz[5], Enid Montague, PhD[1]
[1]Northwestern University, Chicago, IL; [2]National University of Singapore, Singapore; [3]Mayo Clinic, Rochester, MN; [4]NorthShore University HealthSystem, Evanston, IL; [5]Vanderbilt University, Nashville, TN

Abstract
In the course of developing phenotype algorithm definitions, graphical tools and query editors are often used to assist with abstracting away the complexities of the underlying data. Many tools have been created and reported in the biomedical literature to assist with definition building, but no work to date has performed a comparison of the features available in these tools. This work conducts a preliminary analysis of the features available in ten publicly reported tools for phenotype algorithm authoring.

Introduction. Phenotyping is the process of systematic collection and analysis of phenotypic data [1]. The implementation of electronic health records (EHRs) on the national scale has a potential to tremendously scale the phenotyping process for clinical research [2]. However, one challenge is the lack of a validated tools to author and apply standardized phenotype algorithms across different sites and EHR systems accurately and efficiently [3]. The aim of this study was to identify and evaluate platforms that may be used to author phenotype algorithms.

Methods. The research team identified a number of tools that are able to construct phenotype definitions of varying complexity, through literature review and expert inquiry. These platforms were evaluated for the following functionality deemed by the study team to be relevant to phenotype construction and/or execution: capability of using temporal operators (specific date, time interval, time overlap, and time sequence) and Boolean operators (basic and nested AND/OR and NOT), search functions (search by codes, keywords, and other advanced search functions), user interface (dashboard display of results, web-based application, drag-drop function, and chart visualization), and other functions (information returned from query and if the platform is open source). Evaluation was conducted on published materials supporting the tool, including scientific publications, system documentation, and execution of public demos.

Results. Ten platforms that can be used for authoring phenotype algorithms were identified and reviewed; the Biomedical Translational Research Information System (BTRIS), Duke Enterprise Data Unified Content Explorer (DEDUCE), eMERGE Network Record Counter (eRC), Eureka!, HealthFlow, Informatics for Integrating Biology and the Bedside (i2b2), Measure Authoring Tool (MAT), Stanford Translational Research Integrated Database Environment (STRIDE), Visual Aggregator and Explorer (VISAGE), and Vanderbilt University's Synthetic Derivative (VUSD). With respect to certain features, six of the ten tools lacked the ability to relate items occurring at the same time. Only four of the ten made their source code readily available, and three of the ten were created for a specific institution or network. Additional details of the analysis will be presented.

Discussion. While there is a great deal of overlap between functionality in the reviewed systems, there is also great variance, which may be attributed to the different scenarios for which the tools were designed. For example, tools such as the MAT are used purely for logic representation and not execution, and the eRC and i2b2 serve as platforms for feasibility queries. The lack of temporal operators overall, while often not needed for simple phenotypes, is often used to create more robust phenotype definitions. Future work will evaluate the graphical paradigms used in these tools to implement features, which may be used to inform enhancements and the design of future platforms.

Acknowledgement. This work has been supported in part by funding from the National Institutes of Health (R01-GM105688).

Using EHR Timestamps for Analyzing Ophthalmology Clinic Workflows

Sarah Read-Brown[1*], Michelle R. Hribar, PhD[2*], Leah Reznick, MD[1], Thomas Yackel, MD, MPH, MS[2], Michael F. Chiang, MD, MA[1,2] (*Co-first Authors)

[1]Ophthalmology and [2]Medical Informatics & Clinical Epidemiology; OHSU, Portland, OR

Introduction

Patient flows in clinical ophthalmology are complex: patients see multiple providers, undergo dilation, and may undergo office procedures. Due to the complexity of and multistep nature of this process, patient wait times can accumulate, affecting patient satisfaction[1] and future care[2]. Being able to predict variability and patient exam times has potential to greatly improve scheduling strategies[3]. We propose using timestamps from historical exam data from an electronic health record (EHR) for this prediction, and to validate them with observed time-motion data.

Methods

This study took place at Oregon Health & Science University, focusing on a single ophthalmology provider's clinic (LR). Clinic exams consisted of the following steps: 1) Patients are initially examined by an ophthalmic technician, orthoptist and/or resident, 2) their eyes may or may not be dilated, and 3) they are examined by a physician. The authors (SRB, MRH) observed a clinic for 3 days, using time-motion methods to record the times that patients spent during each part of their exam using a combination of paper and electronic forms. We then compared these observed times to timestamps recorded in the EHR (Epic; Verona, WI) during exams. These included time points such as scheduled appointment time, patient check-in time, check-out time, dilation time, and audit log data. For each provider, we used the timestamps of the first and last audit log entries made during the exam time recorded on workstations in exam rooms. Differences between the observed vs. EHR timestamps were calculated.

Results

Table 1 shows the individual exam times by each provider, as well as total exam times. Overall, 67% of exam times from EHR timestamps fell within 3 minutes of observed times. Among the 14/82 (17%) of exams in which discrepancies between these times were >5 minutes, review of time-motion observation notes determined that providers did not use the EHR at the start of the exam and/or stop using the EHR at the end of the exam.

Table1: Comparison between EHR and Observed Exam Times

Time Difference EHR Timestamp vs. Observed Data					
	< 1 Min	1-3 Min	3-5 Min	> 5 Min	N
Initial Exam	9 (32%)	13 (46%)	5 (18%)	1 (4%)	28
Resident Exam	1 (50%)	-	-	1 (50%)	2
Physician Exam	9 (33%)	12 (44%)	1 (4%)	5 (19%)	27
Total Exam	7 (28%)	4 (16%)	7 (28%)	7 (28%)	25
Total	26 (32%)	29 (35%)	13 (16%)	14 (17%)	82

Conclusion

EHR timestamp data can be used to estimate exam times as long as providers follow a consistent workflow that captures start and end times of exams. This creates potential for using these data for strategies to evaluate and improve clinical efficiency. More work is needed to expand and validate this EHR time stamps method to other providers and clinics.

Abstract

In the Department of Veterans Affairs (VA) project Automated Data Acquisition for Heart Failure (ADAHF) we had annotators annotate documents with and without pre-annotation to assess the impact of pre-annotation of documents on the time required to perform annotation. We found that pre-annotation was statistically significant and saved time on annotation.

Introduction

Human capital is the largest expense in almost all research. In Informatics, a significant task involved in training information extraction algorithms is the time needed for human review and annotation of documents [1]. In the Department of Veterans Affairs(VA) project Automated Data Acquisition for Heart Failure (ADAHF), annotators reviewed documents for concepts related to VA heart failure treatment performance metrics. The annotated documents were used to train algorithms for automated information extraction. We examined the effect of pre-annotation of documents with significant keywords on the time needed to perform annotation.

Methods

The corpus, consisting of 150 documents, was separated into 7 batches, which were then randomly split into three sets. For each set one annotator received the documents preannotated with concepts; the other two annotators received the documents in a raw state with no pre-annotations. Preannotations were created through a combination of machine learning tools [2], which detected ejection fraction related concepts, and a dictionary lookup, which detected medication related concepts. The annotators used Protégé [3] with the Knowtator plugin [4] to perform the annotation task. Time for each annotator to complete the task was measured and recorded in a spreadsheet.

Statistical Methods

The statistical model used fit the log transformed time with the effects of annotator, pre-annotation status, and their interaction, with a random blocking effect for the document to adjust for document complexity. The model was checked for and satisfied standard validity checks for linear models. Similar papers have reported on the benefit of preannotation before [1] [5] [6], however we additionally modeled the effect of preannotation with the effect of individual annotators as well as the possible interaction between annotators and preannotation.

Results

Similar to Lingren et al. [6], preannotation reduced the time required by 13%. For a typical document in our corpus, pre-annotation saved 8.7 seconds from a total 66.4 seconds in the annotation task. The log transformation in the analysis indicates that the larger number of concepts and the longer the document (the annotation task) the more pre-annotation will reduce time; for example, if a document would otherwise take 2 minutes to annotate, pre-annotation would take a full 15.8 seconds off the total time of the annotation task. We found both the annotator and the pre-annotation effects to be statistically significant, and the interaction to not be significant. In comparison the effect from the annotator is larger than the effect from the pre-annotation.

Discussion

We found that all annotators benefit similarly from pre-annotation. However, the pre-annotation does not outweigh the effect of individual annotators, indicating that pre-annotation does not substitute for well-trained and efficient annotators.

Visualizing Technology Types for Gait Speed Detection in Older Adults

Blaine Reeder, PhD[1], Kamin Whitehouse, PhD, MS[2]
[1]University of Colorado, Aurora, CO [2]University of Virginia, Charlottesville, VA

Abstract

Gait speed is a predictor of adverse events in older adults. We conducted an integrative review of gait speed technologies used in studies that enrolled older adult participants to identify distinct detection approaches and the potential for these technologies to support gait speed monitoring in everyday life. This presentation provides a visual overview of gait speed technology types and future directions for research in this area.

Introduction

Changes in gait speed are an important indicator of functional change in older adults. Slow gait speed is associated with falls, mobility limitations, hospitalization and mortality[1]. Older adults prefer to live independently in their own homes or "age in place". Technologies that monitor gait speed in everyday life have the potential to support this desire through alerts in functional change. Recent years have seen a number of different approaches to monitor gait speed at home but reported evidence is fragmented because it is indexed in discipline-specific literature repositories. To address this gap, we conducted an integrative review of gait speed technologies. Here we present a visualization of gait speed technology types identified during our review.

Methods

Using Whittemore and Knafl's methodology[2], we conducted an integrative review of technologies to detect gait speed used in studies that enrolled older adult participants. PubMed and IEEE Xplore databases were searched with keyword synonym groups for "gait speed", "sensor" and "older adult". Five hundred thirty-nine total articles were identified for review. Technologies were classified according to type and visualized in a graphic to facilitate explanation and understanding of their function.

Results

Sixteen articles that described ten different technology types published between 2002-2014 were included. Technology types were split into categories of *installed* and *body-worn* sensors (Figure 1). Installed sensors provide comprehensive home-based data but video may present privacy challenges. Worn sensors provide data outside the home but present adherence issues. In just over a decade, gait speed technology research has advanced beyond the use of customized research hardware prototypes to the point where use of consumer available technologies is common.

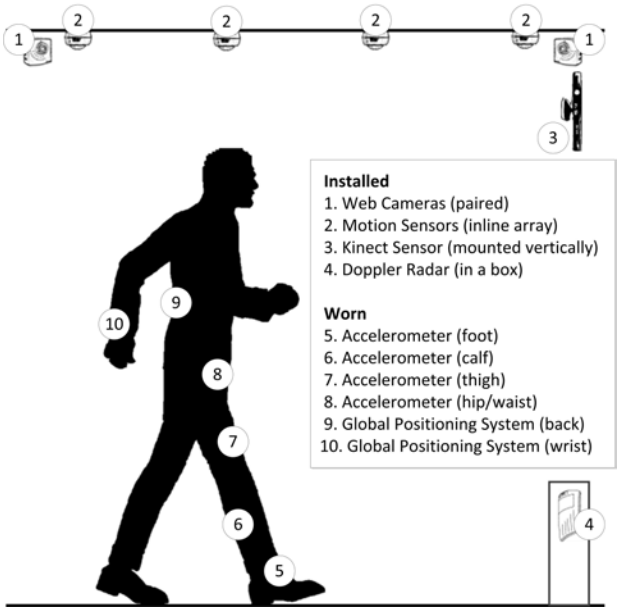

Figure 1. Types of installed and body-worn gait sensors

Conclusion

Gait speed technology research still requires deep technology expertise and substantial integration efforts to achieve research aims, especially with regard to data analysis and presentation. Future research should include development of visualization software and exploration of ways to incorporate gait information into personal health records, health care provider workflows, and older adults' everyday lives to support behavioral interventions for independent living. In addition, older adults' perceptions of different technology types should be compared within the same studies.

Incorporating an Electronic Ventilator-Associated Event (VAE) Tool within a Hospital's Internal Electronic Surveillance System

Ervina Resetar, MIM, PMP[1,3], Kathleen M. McMullen, MPH, CIC[2], Anthony J. Russo MPH[2], Joshua A. Doherty, BS[3], Kathleen A. Gase, MPH, CIC[3], Keith F. Woeltje, MD, PhD[1,3]

[2]Barnes Jewish Hospital, Saint Louis, MO
[3]BJC HealthCare, Saint Louis, MO

Abstract
Mechanical ventilation provides an important, life-saving therapy for severely ill patients, but ventilated patients are at an increased risk for complications, poor outcomes, and death during hospitalization.[1] Using electronic health record (EHR) systems along with microbiology, vital signs, and antibiotic data, BJC HealthCare implemented an electronic Ventilator-Associated Event (VAE) tool and incorporated it within an existing, intranet based, electronic surveillance system.[2] Incorporating the electronic VAE tool resulted in a reduction of Infection Prevention (IP) labor efforts involved in identifying VAE cases and provided a foundation for electronic reporting of VAE cases to the National Healthcare Safety Network (NHSN).

Background
Healthcare-associated infections (HAI) are an important cause of preventable harm in hospitalized patients. Ventilator-associated pneumonia (VAP) is among the most common HAI, but accurate surveillance for VAP has been historically difficult because of the lack of objective definitions. The Centers for Disease Control and Prevention (CDC) National Healthcare Safety Network (NHSN) Working Group developed a new and more objective approach to surveillance that focuses on Ventilator-Associated Events (VAE). These include Ventilator-Associated Conditions (VAC), Infection-related Ventilator-Associated Complications (IVAC), possible VAP and probable VAP.[1] Using the previous VAP definitions, Infection Prevention (IP) staff at BJC HealthCare (BJC) spent approximately 10 hour per intensive care unit (ICU), equating to about 60 IP hours per month at just one facility.

Methods
In response to this surveillance burden, BJC developed an electronic VAE tool and incorporated it within an existing, intranet-based, electronic surveillance system called Surveillance Assistant (SA).[2-3] The clinical decision support system (CDS) consists of registration, lab, vital signs, pharmacy, microbiology and selected nursing assessment data (including ventilator-control settings data), allowing BJC to implement a VAE tool for electronic surveillance for the respiratory status (VAC) and the infection and inflammation components (IVAC) of VAE. Amount of IP staff time spent completing surveillance for VAE was quantified pre- and post-successful implementation of the electronic algorithm.

Results
Prior to the successful launch of the electronic algorithm, IP staff continued to commit about 10 hours per unit per month (60 hours/months) manually applying the NHSN VAE definitions. As a result of this implementation project, the electronic VAE tool automatically identifies new VAC and IVAC cases on a daily basis and loads them into SA. The SA interface provides IP staff with patient level detail data needed for accurate determination of possible and probable VAP; IP staff makes the appropriate selections and saves that information using the same web interface. The complete automation of the VAE definitions decreased IP surveillance time to about 30 minutes per unit per month (3 hours/month), saving roughly 57 hours of IP time monthly in one facility.

Conclusion
Implementation of an electronic VAE tool and integrating it within existing electronic surveillance tools resulted in reduction of labor efforts involved in manual application of VAE algorithm and provided a solid foundation for electronic reporting of VAE cases to NHSN.

Using participatory design to optimize capture of information needed for public health reporting processes

Debra Revere, MLIS, MA[1], Jennifer Williams, MPH[2], Rebecca Hills, PhD, MSPH[1,3], Shaun J. Grannis, MD, MS[2,4], Brian E. Dixon, PhD, MPA[2,5,6]

[1]School of Public Health, University of Washington (UW), Seattle, WA; [2]Center for Biomedical Informatics, Regenstrief Institute, Indianapolis, IN; [3]School of Nursing, UW, Seattle, WA; [4]Indiana University (IU) School of Medicine, Indianapolis, IN; [5]IU School of Informatics and Computing, Indianapolis, IN; [6]Dept of Veterans Affairs, VHA, HSR&D Service, Indianapolis, IN

Objective. To engage public health end-users in the participatory design of Communicable Disease Report (CDR) forms that are pre-populated with HIE-derived clinical data (patient demographics, laboratory results, and treatment) and transmitted via the HIE.

Background. Prior research demonstrates a need to improve public health (PH) agencies' ability to more completely and accurately capture routinely collected CD case information from clinical providers. Traditionally these processes involve manually completed paper forms by providers and/or clinic staff. In settings that utilize electronic health record systems, one proposed pathway for improvement is deploying CDR forms pre-populated with electronic data derived from clinical care settings.[1] Participatory design (PD) principles advocate including real users and stakeholders when designing an information system to ensure high ecological validity of the product, incorporate relevance and context to the design, reduce misconceptions designers can make due to insufficient domain expertise, and ultimately reduce barriers to adoption of the system.[2] Prior to deploying a pre-populated CDR form, we engaged PH users and stakeholders as co-designers.

Methods. Over a 9-month period, we engaged stakeholders in a multi-phase PD process as follows:

1. Initial Focus Groups: Focus groups (5-6 participants/group) were held with PH health stakeholders representing communicable and infectious disease investigation in two PH agencies to review the list of existing CDR form data elements and identify data elements that PH routinely request from clinical reporters and are desirable for inclusion on a CDR form, focused on seven high-priority conditions previously identified by PH: Chlamydia; Gonorrhea; Hepatitis B, acute; Hepatitis C, chronic; Histoplasmosis; Salmonella; and Syphilis.
2. IT Input: Project staff held meetings (n=4) with IT staff to categorize and document the technical feasibility of extracting both existing and additional desirable data elements.
3. Survey: Practitioners and investigators from the two PH agencies prioritized data elements feasible for extraction with regards to data needed to close a CDR case.
4. CDR Form Mock-ups: Based on survey data, IT staff developed a modified, pre-populated CDR form mock-up for each high-priority condition.
5. Closing Focus Groups: The original PH stakeholders reconvened to review and achieve consensus on the collated list of final prioritized data elements and provide feedback on the CDR form mock-ups.

Results. By involving PH users in a PD process, we made significant improvements to the layout and functionality of the forms. Focus groups with PH stakeholders identified a number of state-mandated fields that are not highly used or desirable for disease investigation and their elimination allowed engineers to focus on re-purposing form space to capture higher priority data elements. Establishing appropriate user expectations is a critical factor with respect to adoption and receiving early input through PD methods provided new insights into PH workflow and allowed the team to quickly triage user requests while managing PH user expectations within the realm of engineering possibilities. A final CDR form for each condition was designed to meet the needs of PH stakeholders and the technical capabilities of the HIE to automatically pre-populate the forms with available, prioritized data elements. Deployment of the modified, automatically pre-populated CDR forms is in process in pilot clinic settings and evaluation of these improvements on CDR data quality and reporting rates is ongoing.[3]

Conclusions. Innovative IT strategies must be aligned with the requirements and expectations of their users. Engaging PH as a co-designer not only ensured the new CDR forms will meet real-life needs, but also will support development of a product that will improve CDR reporting.

Patient Perspectives of Mobile Phones' Effects on Healthcare Quality and Medical Data Security and Privacy: A Nationwide Survey

JE Richardson, PhD, MLIS; M Silver, MS, JS Ancker, MPH, PhD
Center for Healthcare Informatics and Policy, Weill Cornell Medical College, NY, NY

Abstract: *Given the growing interest in utilizing mobile phones including cell phones and smartphones for health management, we sought to gauge consumer perceptions of these technologies as related to security, privacy, and healthcare quality. A national random-digit-dial telephone survey was conducted in 2013. Subjects were more likely to endorse the belief that medical data on mobile phones would worsen privacy and security than they were to express similar concerns with electronic health records (EHRs) or health information exchange (HIE). Fewer than half of respondents endorsed a statement that using mobile phones to share personal health data with physicians would improve healthcare quality, which was much lower than the percentage who agreed that physicians' use of EHRs or HIE would improve quality. Consumer security and privacy concerns may need to be addressed before the application of mobile phones for healthcare quality improvement can be fully realized.*

Introduction

Healthcare researchers perceive mobile phones as having the potential to revolutionize the ways in which consumers collect, monitor, and share their medical data with providers.[1] Yet consumer concerns around data privacy and security may limit use[2] and thus negate any potential healthcare quality improvements that could result. We therefore wanted to gauge consumer perceptions of mobile devices on medical data security and privacy, so to inform policies that can target mobile devices as ways to improve healthcare quality.

Methods

In 2013, we conducted a national random-digit-dial telephone survey of subjects with access to landline telephones and cell phones in the United States. Subjects were asked whether healthcare quality and the privacy and security of medical information would improve or worsen with the use of specific technologies: electronic health records (EHRs), health information exchange (HIE) among physicians, and cell phones/smartphones used to store medical data or send it to a physician's EHR.

Results

A total of 1000 respondents were included (a 64% response rate), producing a 3.1% margin of error. Most respondents endorsed the belief that privacy and security would worsen if mobile phones were used to store personal medical data (74%) or send this information to a physician's EHR (69%). By contrast, only 41% expressed similar privacy and security concerns about EHRs or HIE as used by physicians. Fewer than half of respondents endorsed a statement that using mobile phones to share data with physicians would improve healthcare quality (48%), which was much lower than the percentage who agreed that EHRs or HIE would improve quality (61% and 74%). Respondents who believed that EHRs would improve healthcare quality were nearly 3 times as likely to believe that using a mobile device to share data with an EHR would also improve healthcare quality (OR 2.94). Younger individuals were slightly more likely to believe that mobile phones would improve healthcare, but age was not associated with privacy concerns.

Discussion

Despite the growing popularity among consumers for using mobile phones and health-related mobile applications, consumers have concerns about the privacy and security of medical information, and many are skeptical that using mobile phones to share information with physicians will improve healthcare quality. Consumer security and privacy concerns may need to be addressed before the application of mobile phones for healthcare quality improvement and patient engagement can be fully realized.

The UCDHS Tethered Meta Registry: A Tool for Patient Health and Organizational Quality Improvement

Albert Riedl, MS; Larry Errecart; Sharon Myers, PhD, MPH; Colleen Gordon, MS; Kent Anderson, MS
UC Davis Health System, Sacramento, CA

Abstract

The UC Davis Health System has demonstrated successes in the secondary use of Electronic Health Record (EHR) digital content: EHR content has been summarized to create clinical outcome databases and registries, and where appropriate, clinical data has been de-identified and loaded to Cohort Discovery (i2b2) and other research support software datasets. Challenges to further leveraging clinical data re-use for population health and decision making include data fragmentation or duplication between systems, lack of data entry standards, and the amount of contextual knowledge required to understand the data. Further complicating data re-use is the ongoing evolution of EHR implementation and slow adoption of national healthcare data standards, thus limiting industry knowledge transfer to methodological sharing. UCDHS developed the Tethered Meta Registry (TMR) to overcome fragmented and erroneous data, encourage common institutional data standards and definitions, highlight the importance of data contexts, and integrate with industry standards.

Introduction

The UC Davis Health System captures data across a myriad of clinical and supporting IT systems. Although paperless, the majority of these systems are not designed for data reporting or analysis, nor does any single system contain a complete picture of institutional operations or patient care at the population level. Furthermore, patient data sets or registries that were created to meet departmental or organizational measurement objectives were done so independently and managed in isolation. Although UCDHS has demonstrated success in the re-use of electronic health records, the challenges to advancing this initiative further are data fragmentation, duplication between systems, incomplete data, data errors, and lack of comprehensive data entry standards.

Strategy for Change

The paperless infrastructure at UCDHS is leveraged to create a Tethered Meta Registry (TMR), bringing together various silos of clinical content including EHR, billing and coding, radiology, and Laboratory Information Systems. The TMR is a repository of curated data based on the Epic EHR and augmented by high value raw and derived data from other source systems. These curated data are maintained via a 'tethered,' near real-time connection. 'Meta Registry' refers to a series of tested and validated data sets, known as registries. These registries emerged from the institutional mission to improve patient care, optimize operations, and centralize and standardize external reporting. Each registry is created in partnership with key subject matter experts who understand the data within the tethered systems. Each registry also expands the breadth of the TMR, adding data elements for future use and allowing for cross-registry interoperability.

Results

Currently, the TMR manages about 300 defragmented, de-duplicated, well understood data concepts, aligning over 1 billion data points, and supporting registries which vary in purpose from clinical quality improvement to patient and disease tracking. The TMR has spurred quality improvement projects reducing mortality in critical care settings (specifically, reducing sepsis mortality by 25%), freed resources previously spent on data entry/documentation, helped direct resource allocation across the primary care network, informed the improvement of clinical documentation workflow, and supported numerous grant applications leading to incoming extramural funding. Additionally, it has catalyzed institutional involvement encouraging participation and developed lasting strategic partnerships in UCDHS's effort to re-use clinical data.

Conclusion

The TMR is an effective and efficient way to produce registries to identify, track, and analyze patient populations as well as the care they receive. By providing this information to the clinical teams in a meaningful way, care can be improved. The TMR development process has led to increased institutional engagement in data management, furthering a shared understanding and shared ownership of registry data sets.

Error Propagation in EHRs via Copy/Paste: An Analysis of Relative Dates

Kirk Roberts, PhD, Amos Cahan, MD, Dina Demner-Fushman, MD, PhD
U.S. National Library of Medicine, Bethesda, MD

Abstract

We present a method for identifying errors in EHRs caused by copying and pasting text containing relative dates. Our method utilizes a sequence alignment method for recognizing instances of copy/paste, and regular expressions for relative dates. We furthermore present an analysis of our method on the MIMIC-II dataset.

Introduction

Electronic health records (EHR) are a powerful enabling technology, but concerns exist about the dangers of copying text from one clinical record to another.[1,2] While strategies exist for mitigating copy/paste in text mining approaches, little work has been done to evaluate the types of errors introduced to the EHR through copy/paste. This work studies errors due to the copying of relative dates. When a note contains a relative date (e.g., "*3 days ago*", "*past 4 weeks*", "*43 y/o*"), performing temporal reasoning requires this date be grounded, typically to the date the report was written. However, if the text is copied to a later report, the ability to ground this date is lost. We propose a method called DupLink, which links pasted text back to its original source (Figure 1). We then utilize regular expressions to identify relative dates in pasted text, enabling such cases to be flagged or even automatically corrected.

Methods

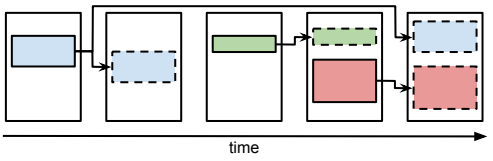

Figure 1: DupLink

DupLink recognizes copy/paste using Smith-Waterman local sequence alignment, a dynamic programming algorithm for detecting similar regions from two sequences. For each patient in MIMIC-II[3], reports are chronologically ordered, and Smith-Waterman is run pairwise to identify duplicate spans. A text span can act as the source (copy) to any number of targets (paste); a target can only have one source, creating the linking structure in Figure 1. DupLink iteratively finds the best local alignment on each report pair until no more high-scoring alignments are found. For each instance of copy/paste, regular expressions identify six classes of relative dates, best illustrated by example: (P1) *fourteen days ago*, (P2) *last year*, (P3) *on Saturday*, (P4) *yesterday*, (P5) *this July*, (P6) *45 years old*. To evaluate the severity of copying errors, we used five classes: (C1) *updated* in the pasted text, (C2) *valid*, as little time has passed, (C3) *resolvable* by a nearby absolute date, (C4) inconsistent, but *minor*, and (C5) inconsistent, and *serious*. Some analysis can be performed automatically (e.g., when reports are from the same day), otherwise human analysis is necessary. An experienced internist (AC) annotated a sample of each of the six pattern classes.

	matches	annotations	%C1	%C2	%C3	%C4	%C5
P1	156	142 (100)	-	53	26	20	2
P2	50	50 (7)	-	86	2	8	4
P3	47	47 (18)	11	85	4	-	-
P4	1278	731 (100)	6	62	17	12	1
P5	790	432 (100)	8	71	9	9	-
P6	388	199 (100)	-	100	-	-	-

Table 1: Results. Annotations in parenthesis are the manual annotations. Percentages are projections from manual and automatic annotations.

Results

See Table 1. Given the size of MIMIC, there were few instances of copy/paste. In other institutional cultures, however, copy/paste is more prevalent. Most copy/paste instances in MIMIC occur on the same day (C2). The resolvable class is the next most common, suggesting there are many relative dates that should be resolved to a local anchor instead of the report date. While few serious inconsistencies were found, they do exist along with many minor inconsistencies. This suggests the importance of integrating a copy/paste detection system like DupLink into the EHR. Further information as well as a software implementation of DupLink can be obtained by contacting the authors.

An International Evaluation of User Perceptions of Drug-Drug and Drug-Allergy Interaction Alerts

Alexandra Robertson[1], Pamela Neri, MS[2], Elisabeth Burdick MS[1], Sarah P. Slight MPharm, PhD, PGDip [1, 3], David W. Bates MD[1, 2, 4], Shobha Phansalkar RPh, PhD [1,4,5]

[1]Division of General Internal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Partners HealthCare, Wellesley, MA; [3]School of Medicine, Pharmacy and Health, University of Durham, UK; [4]Harvard Medical School, Boston, MA; [5]Wolters Kluwer Health, Indianapolis, IN.

Background

Electronic medical records (EMRs) with integrated CDS have the potential to improve medication safety. Increasing adoption, refining the delivery and content of existing CDS, and improving user-centered design are key to meeting core measures for Meaningful Use. However, only limited evidence supports a direct link between CDS and measurable improvements in patient safety. Poor user acceptance of alerts, poor alert design, and lack of contextual specificity have been cited as causes for negative perceptions about the utility of CDS, alert fatigue, and override rates which are estimated to be as high as 49-96%.

Methods

To understand the relationship between alert-acceptance and user perceptions of the number and content of alerts, we surveyed physician perceptions of DDI and DAI alerts via a validated survey tool developed by Zheng, et al.[1] We surveyed users of 4 home-grown and 2 vendor systems across 7 multi-national institutions. 1,423 internal medicine physicians were invited to participate. To assess the impact of provider perceptions of the volume of alerts they receive, providers were asked to quantify the DDI/DAI alerts they: (a) received in an average week, (b) read thoroughly, (c) found clinically relevant, (d) felt changed their prescribing behavior, and (e) overrode.

We performed descriptive statistics of responses to establish correlations between perceptions of alert frequency, alert relevancy, and alert override. We ran means in 3 groups based on the number of alerts reported per week; 1-10 alerts/week (group 1), 11-50 (group 2), and greater than 50 (group 3).

Results

Of the 1,423 physicians invited, 342 consented to participate for a response rate of 24%. Overall, participants estimated receiving a greater number of DDI (22.9) than DAI (13.8) alerts per week, but were more likely to override DAI than DDI alerts, with reported override rates of 83.22% and 78.5%, respectively. For both DAI and DDI alerts across all 3 groups, we found that as the number of perceived alerts increases, the percentage of providers who report reading, finding these alerts relevant, or changing prescribing behaviors, based on the information provided, decreases, while the number of alerts overridden increases.

Physicians who reported receiving greater than 50 DDI/DAI alerts per week also reported reading only 25.4/30.5%, finding only 25.5/7.8% clinically relevant, identifying only 15.2/16.5% as changing their prescribing behavior, and reported overriding 90.4/96.9%, respectively. Comparatively, those who reported receiving between 1-10 DDI/DAI alerts per week reported: reading 69.6/82.7% of those alerts, finding 40.7/55.1% clinically relevant, identified 34.7/48.5% as changing their prescribing behavior, and overrode 64.2/68.5%, respectively.

Conclusions

This is the first study to establish an empirical correlation between physician perceptions of alerts and alert acceptance. Physicians who believe they receive a high number of alerts are less likely to read them, find them clinically relevant, allow them to affect their prescribing behavior, and more likely to override them. Future research should focus on how perceptions of alert volume can be improved. Decreasing the volume of interruptive alerts may foster more positive physician attitudes towards CDS alerting in EMRs.

The importance of mental models in the design of integrated PHRs

Inês Rodolfo, BA[1]; Liliana Laranjo, MD, MPH[2]; Nuno Correia, PhD[1]; Carlos Duarte, PhD[3]
[1]Faculty of Science and Technology, UNL, Lisbon, Portugal; [2]Portuguese School of Public Health, UNL, Lisbon, Portugal; [3]Faculty of Science, UL, Lisbon, Portugal

Abstract
In order to address the challenges of designing a national integrated personal health record (PHR), we conducted remote software-based individual and closed card sorting sessions to detail mental models for the creation of a meaningful information architecture. We were able to compare how people from different user groups (senior people, younger people, healthcare professionals and non-professionals) think about PHR-related content

Environment relevance and problem
Several government programs around the world are implementing healthcare system reforms with the goal of creating sustainable networks that combine interoperable health information collected both from healthcare providers and patients. In this context, integrated PHRs have emerged. The main difference from stand-alone and tethered PHRs is that this model has the ability to incorporate patient self-reported information with data from multiple health-related sources [1], providing holistic views of each patient's health. Our research is focused on a design proposal for our National Patient Portal in the scope of the European Patients Smart Open Services project. The platform combines this new PHR model counting over 750, 000 registered users who can access their unique summary care record and use both healthcare services and self-tracking tools to manage their health. Past research revealed the need to detail mental models of lay individuals and providers in order to achieve comprehensive system information architectures that reflect the patient's roles and needs [2]. This need inspired the goal of this study: to create content and navigation structures that respond to the involved user profiles: providers who need to access patient's data and the citizens who use the platform (including the difference between younger and older adults).

Methods
For the portal redesign we followed a user experience design approach to gain more understanding of users, combining functional analysis with other emotional and social aspects of people's relations with technology. To detail mental models we applied card-sorting, an evaluative straightforward method that helped us understand and compare how people think, label, and organize content in a way that makes sense to them [3]. We applied closed card sorting because of the complexity of health content. Through this method we evaluated the first two navigation levels of the system information architecture (IA), developed from a previous extensive literature review and functionality gathering process. We had a total of 73 participants representing two user groups as a result of two different participation environments (a senior university and through social networking): a senior user group with whom moderated sessions were held in a senior university with 11 participants (average age: 64); and a broader audience group (average age: 33) with whom remote sessions were conducted during 4 days with 62 participants.

Results and conclusions
The results influenced significantly the final structure of the IA. Both first and second navigation levels suffered changes in the given category labels and content grouping. The first level groups that worked best for both user groups were "Personal information", "My Health" and "Health Education". The groups that presented more conflicts and doubts for both user groups were "Healthcare Management" and "Healthcare System". As expected, healthcare professionals were the ones who showed more agreement with the initial IA, as they are more aware of how the healthcare services work and more comfortable with clinical content, in comparison with lay people. We did not find significant differences between the mental models of senior people and other demographic groups, except regarding 'Privacy Control' content. This is probably due to the fact that senior people are less used to this type of content when compared to younger people, who tend to have more software experience. We also considered participants' suggestions and comments in the IA restructure: e.g., to divide "My Health" group into two other sub-levels ("Health History" and "Basic Information") as this group was considered to be too overwhelming.

Abstract

Medication reconciliation and clinician-friendly recording of medication is an ongoing informatics challenge. Users often prefer unrestricted free-text entry. We sought to see if simple Natural Language Processing (NLP) methods can be used to convert real-life medication records into coded concepts without additional interface changes to clinicians. We used data from the National Institutes of Health Clinical Center (NIH CC). Outpatient medications are recorded by research nurses using a semi-structured form that does not alert for incorrect data entry. We present data on accuracy of the NLP pipeline and suggest improvements to RxNorm tools.

Objective: To utilize simplified automatic NLP tools for drug entry harmonization.

Materials and Methods: We used National Library of Medicine's RxNorm API through the RxMix tool (http://rxnav.nlm.nih.gov/, accessed on 2014-01-30) to convert free-text medication entries into RxNorm concepts, namely RxNorm ingredients**.** Medication free text entries were first preprocessed with regular expressions to extract the drug names, drug strength, and drug forms from the original string that also included dosing and frequency information. The resulting simplified string was processed using the function *getApproxMatch* to find matching concepts in RxNorm (RxCUIs). The RxCUI was then processed using the *getAllRelatedInfo* function to obtain the ingredient and additional information. We used the concept match score and rank provided by the *getApproxMatch* function to further consider only well-matched concepts. For example, from the original input string: "*Metronidazole 250 mg , 2 tablet , PO , Every 12 hours.*", we first extract the drug entity "*metronidazole 250 mg*", which maps to the RxNorm concept *"Metronidazole 250 MG"* (316300) with a score of 100. Its ingredient is *"Metronidazole"* (6922). The remainder of the input string drug dose and frequency can be used to estimate drug doses or as part of a free text drug entry system automatic fill option.

Results: The original 43,303 medication strings were preprocessed into distinct 9,466 drug input strings. A total of 5,680 (60%) strings mapped to either RxNorm Ingredient (IN) concept or Clinical Drug (SCD) or both. Online appendix at http://dx.doi.org/10.6084/m9.figshare.960060 shows complete numerical results together with the impact on the string mapping counts when score thresholds are used to classify strings into two scenarios: (A) likely correction to a single target concept (score 80-100; single misspelled character: *"atenlol"* to *"atenolol"*) or (B) nurse may be asked to pick the best term from several matching contexts (score 50-79; multiple misspellings). A total of 502 concepts had either no matches or a score of less than 50 most of which are not ingredients or meaningless strings eg: *"vitamin juice", "zyrec"*.
