Introduction: Many hospitals routinely perform antimicrobial susceptibility testing for bacterial pathogens. The results are often organized into a summary table, or antibiogram, that clinicians use as a reference guide for antimicrobial resistance patterns. Antibiograms display information that can be used to raise awareness of resistance problems, support the use of optimal empiric therapy, and identify opportunities to reduce inappropriate antibiotic usage.[1] Most hospitals distribute an institution-specific antibiogram as a static document that is generated from laboratory data on an annual basis.

Anesthesiologists and surgeons must select and administer perioperative antibiotics either for prophylaxis or to treat an active systemic infection. To assist in this decision-making process, we developed a secure, Web-based, institution-specific, user-friendly visual analytics antibiogram dashboard using electronic health record (EHR) data in near real-time that can be accessed in the operating room setting using the anesthesia information management system computer workstation.

Methods: We created a visual analytics antibiogram dashboard using both Structured Query Languge queries of our EHR database and enterprise visual analytical software to track bacterial pathogens and their antimicrobial sensitivity at CHOP. (Figure 1) The antibiogram dashboard provides a user interface to explore our hospital's laboratory EHR data in near-real time and facilitates the rapid assessment of susceptibilities and resistances of microorganisms to various antibiotics.

Results: A visual analytics antibiogram dashboard specific to our institution was designed and implemented as described in the methods. The dashboard allows the user to display up-to-date, hospital-specific antibiotic sensitivity data for a particular organism using a variety of filters, groupers, and drop down menus.

Discussion: Pediatric anesthesiologists and surgeons must consider many factors when selecting and administering perioperative antibiotics. While infectious disease specialists usually guide the antibiotic choices and dosages, there remains a dearth of information at the time of antibiotic administration in the operating room regarding the susceptibility of organisms to the chosen antibiotic. We created a visual analytics antibiogram dashboard that incorporates near-real time laboratory and pharmacy data regarding organism speciation, antibiotic susceptibility, and the cost of antibiotic options. This dashboard will be an integral part of a project to optimize perioperative antibiotic treatment based on our hospital's EHR data.

Abstract: *Characterizing individual physician variations in use of EHR features may be informative as a predictor of the effects of EHRs. The current study is designed to assess the relationship between use of individual EHR features and "meaningful use" healthcare quality measures at the physician level. Use of EHR features and 17 "meaningful use" clinical quality measures were evaluated on the basis of encounters from January 2012 through June 2013. Use of condition-specific best-practice alerts (BPAs) and order sets was associated with better scores on clinical quality measures that captured processes relevant to diabetes, cancer screening, tobacco cessation, and pneumonia vaccination. In the early stages of the "meaningful use" program, use of specific EHR features was associated with modest improvements in certain quality measures focusing on healthcare processes, rather than healthcare outcomes. Longer-term follow-up may be required to link improved processes to outcome performance.*

Introduction: Studies of the effects of electronic health records (EHRs) on healthcare quality have produced mixed results. As more physicians adopt EHRs in the era of "meaningful use," characterizing individual physician use of EHR features, rather than simply assessing the availability of an EHR, may create more informative predictors of the effects of EHRs (1, 2). The current study is designed to assess the relationship between use of individual EHR features and "meaningful use" healthcare quality measures.

Methods: In this cross-sectional study, we included all encounters by primary care providers eligible for meaningful use at a federally qualified health center (FQHCs) network. Use of EHR features and 17 "meaningful use" clinical quality measures were evaluated on the basis of encounters over 18 months. Negative binomial regression models were run to assess the association between feature use and quality on the level of the provider.

Results: Sixty-five providers were included. Use of condition-specific best-practice alerts (BPAs) and order sets was associated with better scores on clinical quality measures that captured processes relevant to diabetes, cancer screening, tobacco cessation, and pneumonia vaccination. For example, responsiveness to breast cancer screening alerts was associated with higher rates of breast cancer screening (incidence rate ratio [IRR] 1.004; $p < .001$) and responsiveness to diabetes-relevant alerts was associated with better performance on measures of diabetes foot exam performance (IRR 1.003; $p = .004$) and LDL testing (IRR 1.006; $p < 0.001$). By contrast, use of the same EHR features was not positively associated with performance on most quality metrics that focused on healthcare outcomes (such as number of diabetes patients with LDL < 100 mg/dL).

Discussion: In the early stages of the "meaningful use" program, use of specific EHR features was associated with modest improvements in certain health care quality process metrics assessed through EHR data, but not with most outcomes-focused quality metrics. Longer-term follow-up may be required to determine whether improved processes will lead to improved outcome performance. The EHR features associated with improved processes may be instrumental in improving the quality of healthcare delivered by physicians who use EHRs. The results may also provide guidance for continued improvements in EHR design as well as end-user training.

Title: Physicians' Use of Electronic Health Records (EHRs) as a Communication Tool in Primary Care Visits.

Introduction: Some recent studies advocate that EHRs can be used as a tool to communicate and share information through screen with patients during the clinical encounter; therefore, EHRs in the exam room can contribute to patient-centered goals such as making patients more empowered and activated. Our previous studies indicated that, not only do different physicians tend to take very different approaches regarding interacting with EHR, but a single physician might also have different screen sharing behaviors from visit to visit. The goal of this study is to explore work system factors influencing physicians' information (screen) sharing behaviors in the visit.

Methods: Purposive convenience sampling method was followed to recruit physicians from the clinics. We conducted semi-structured interviews with 14 physicians in total. The interview guide and questions were developed based on the conceptual framework of the study: the work system model. Qualitative content analysis was used to analyze the interview data to identify factors influencing physicians' screen (information) sharing styles during primary care encounters.

Results: The qualitative interview identified factors influencing physicians' decisions to share the screen (20 factors), not to share (14 factors) the screen, and identified 21 facilitators which makes it easier to share the screen and 40 barriers which makes it harder to share the screen. These factors are all grouped under broader categories (educating patients, reviewing results/records, patient interest, physician-patient interaction, decision making, patient demographics, time, policies, physical/mental health, sensitive information, confidentiality, information display and density, patient interest, physician computer skills, patient demographics) and linked to appropriate work system elements.

Discussion: This study showed that there are several significant factors influencing physicians' decisions and behaviors about screen sharing, such as patient related and organizational factors. It was interesting to see that sometimes a single item was reported as a factor influencing a physician's decision not to share the screen by one physician, and a barrier which makes it harder to share screen during the visit by another physician. Physicians mostly reported that screen sharing is beneficial for patients and helps patients to better understand the information provided and become more involved in their own healthcare, although they also noted that current EHRs are not designed as a communication tool. Physicians also reported several advantages of screen sharing: it is a good way to educate the patient, it improves new patient trust in the physician, it helps in shared decision making, and it helps patients to visualize certain things that are hard to conceptualize without a visual aid. Physicians stated that these advantages cause screen sharing to have the potential to foster collaboration between physician and patient, leading to better outcomes in the end, better patient education, better relationships with the patient since the physician in engaging them in their healthcare by sharing the screen, better team work between the patient and physician to improve the patient's health, improved patient understanding of health plans and entered records, and making data entry more transparent so patients have a better trust in physician. Furthermore, two main reasons for avoiding screen sharing were also supported by other studies: 1-Documenting or reviewing sensitive information or legal issues, fake pain, obesity, child abuse, suicide. 2- Lack of time and time pressure. This study is vital to understand barriers and facilitators to HIT information sharing in order to inform better EHR designs.

Multiple Perspectives on Clinical Decision Support: A Qualitative Study of Fifteen Clinical and Vendor Organizations

[7] Vanderbilt University, Nashville, TN, USA

Introduction

Primarily due to current U.S. government incentives through the American Reinvestment and Recovery Act (ARRA),[1] hospitals and ambulatory care organizations are increasingly purchasing commercial electronic health record (EHR) systems with computerized clinical decision support (CDS), and/or they are buying CDS directly from content development vendors. Challenges to CDS development, management, and use are sociotechnical in nature, involving people, processes, and technology.[2]

Prior studies concerning the sociotechnical aspects of CDS have focused on the perspectives of individual healthcare organizations [3-6] or vendors [7] in isolation, with no studies comparing the differing perspectives of each stakeholder group. Moreover, the perspectives of commercial organizations have largely been overlooked.

To capture a picture of the entire CDS landscape including views of multiple stakeholders within and outside healthcare organizations, we pose the following research question: How are the views of clinical stakeholders, CDS content vendors, and EHR vendors alike or different with respect to challenges in the development, management, and use of CDS?

Methods

We used the Rapid Assessment Process (RAP), as previously described, [8] for studying 15 organizations, though we adapted it significantly when studying vendor sites.[7] Institutional review boards (IRBs) at the investigators' institutions and each clinical site with an IRB approved the study. For clinical sites, five inpatient and five outpatient sites were selected based on variation in commercial system used, maturity of CDS use, geography, and governance structure. For commercial sites, we purposively [9] selected three different types of content vendors so that we could gain a more comprehensive understanding of the issues. To select EHR vendor sites, we asked a group of experts from healthcare and industry who regularly offer advice about our investigations [10] to help select one primarily ambulatory EHR firm and one primarily inpatient EHR vendor with strong CDS products from among those used at one or more of our clinical study sites. This would allow us to directly compare what users and vendors said about the same CDS products. At clinical sites, we selected subjects for interviewing and observing based on their CDS-related roles. We made an effort to seek out clinical champions, normal users, and skeptical users in addition to CDS experts. During content vendor visits, we interviewed individuals in particular roles, including the CEO, vice presidents, content development and management staff, technical/interoperability staff, and informaticians. For the EHR vendors, we targeted staff members who were most involved with CDS. Data collection primarily consisted of semi-structured interviews and, at clinical sites, observations. Broad areas explored during interviews and observations at all sites included 1) the meaning of CDS, 2) the culture and history of the organization, 3) knowledge management practices, 4) CDS roles, and 5) challenges and the future of CDS. At clinical sites, we also asked about governance of CDS and at commercial sites we discussed their products, customer use of the products, and the marketplace. A grounded theory content analysis approach was used for analyzing data. [11]

Results

We conducted 206 formal interviews and 268 hours of observation. Figure 1 graphically displays the multiple perspectives of the three groups and the overlapping of themes among them. The groups share views on the importance of appropriate manpower, careful knowledge management, CDS that fits user workflow, the need for

communication among the groups, and for mutual strategizing about the future of CDS. However, views of usability, training, metrics, interoperability, product use, and legal issues differed.

Figure 1. Themes shared by clinical and vendor organization representatives.

Discussion and Conclusion

Recommendations for improvement include increased collaboration, legal protections, manpower training, and research about CDS sharing. A national impetus to improve the value and safety of CDS that would include legal protections and incentives for sharing content would be beneficial.

An Interactive Web-based Interview to Improve Family Medical History Documentation

Adarsha S Bajracharya, M.D., [1] Bradley H Crotty, M.D., M.P.H. [1], Hollis B Kowaloff, B.A., [1]
Warner V Slack, M.D., [1] Charles Safran, M.D., M.S. [1]
1. Division of Clinical Informatics, Department of Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston MA

Introduction: The family medical history (FMH) is underutilized in primary care for risk stratification. Primary care visits are short, and detailed FMHs are often not obtained due to lack of adequate systems for collection and synthesis.(1) Electronic tools for patients can facilitate the collection of these data so that providers have more time to discuss preventive health care.(2) Beth Israel Deaconess Medical Center has been studying computer-based health care interviews since the 1970s. In the early 1990s we deployed an interview for all hospital employees that identified medical problems modifiable by behavior change.(3) Prior studies have shown that computer-based interview modules are well accepted by patients. Studies have shown that both doctors(4) and patients(5) prefer these methods of data collection. A 2009 NIH State of the Science Conference concluded that studies examining methods for more efficiently collecting FMH in primary care settings were urgently needed.(6) The electronic capture of structured family history for first degree relatives is now a Meaningful Use Stage 2 objective, which makes the development and testing of these types of tools timely.(7)

Objectives: Describe use of a new family medical history interview module after deployment in a hospital patient portal.

Design, setting, and participants: We developed and deployed an interactive web-based FMH interview within PatientSite at Beth Israel Deaconess Medical Center in Boston, MA. BIDMC is an academic medical center, and PatientSite, the patient web portal, has over 60,000 registered users, all of whom have access to the FMH interview. Patient use data were collected prospectively, measuring the frequency of access to the interview as well as to the patient portal together with the age and sex of the participants.

Intervention: The computer-based family medical history was developed based on years of experience with computerized medical histories.(4) Patients respond either by clicking on their answer from a list of choices or by typing their entries. The module begins by asking about a particular condition in the family and if the patient acknowledges having that condition in the family, the interview goes on to ask details of that family member. Additionally, the interview allows patients to stop and then to return in the future to complete the interview, if they wish. It collects information about 39 health conditions for first- and second-degree relatives, and patients can also enter health conditions that run in their families but are not included in the structured part of the interview. Information generated is stored in the patient's electronic medical record for providers to review. The module was made available to all patient portal users without formal announcement.

Outcome: The primary outcome measure was the number of patients who used the family medical history interview module.

Results: 44,910 patients accessed PatientSite between 1/1/2014 and 3/12/2014. In the first 51 days of deployment (1/21/14 through 3/12/14), 1,102 patients accessed the FMH module 1,451 times, and of these, 545 (377 women and 168 men) completed the family history interview. Of those who completed the module, rates varied by age (See fig 1). Patients answered to family medical questions in yes, no, Uncertain, don't understand or I'd rather not answer format and, 28 out of 12,326 responses were noted to be in don't understand category. (See fig 2).

Discussion: Our study is one of the first to report on operational deployment of a family medical history interview tool within a patient portal, truly integrated with the EHR. Our results show that patients of all ages—including those over 75 years—are interested in interested in collaborating with their clinicians to provide their family health information, and well-framed questions may contribute to patient use of such a tool. We also note that the module was deployed without any announcement or invitation and yet had rapid participation. We plan to explore why these specific patients used the tool, how they found out the tool was available, and whether online tools like these improve chart completeness, facilitate patient engagement, and support clinical care.

Earlier Switching from Intravenous to Oral Antibiotics Due to eReminders

Patrick E. Beeler, MD[1], Stefan P. Kuster, MD[2], Emmanuel Eschmann, MD[1], Rainer Weber, MD[2], Jürg Blaser, PhD[1]

[1]Research Center for Medical Informatics, University Hospital Zurich and University of Zurich, Switzerland

[2]Division of Infectious Diseases and Hospital Epidemiology, University Hospital Zurich and University of Zurich, Switzerland

Abstract

The impact of electronic reminders encouraging early switches from intravenous to oral administration of antibiotics was studied in a hospital-wide, prospective, controlled trial. The reminders were displayed within electronic health records 60h after onset of intravenously administered antibiotic therapies if some patient-specific conditions were met. This intervention fostered early switching from intravenous to oral antibiotics, and thereby significantly reduced the mean duration of intravenous administration by 17%.

Introduction

Paper-based interventions have been shown to encourage switching from intravenous (IV) to oral (PO) administration of antibiotics thereby improving antimicrobial regimens. Important advantages are associated with an early IV-PO switch: Lower risk of catheter-associated infections, reduced nursing workload, and decreased direct and indirect costs. The purpose of this study was to determine whether automated electronic reminders are able to promote early switching.

Methods

In this controlled before-and-after study, an algorithm – starting 60h after onset of an IV antibiotic – automatically checked whether: (i) the therapy was scheduled for an additional 24h or longer, (ii) neutrophil count of the patient exceeded 0.5 G/l, (iii) body temperature was below 38°C, and (iv) patient had the ability to swallow as indicated by active PO orders. If these conditions were met, a non-interruptive red bar was displayed within the top section of the electronic health record (EHR). By clicking the reminder bar a window appeared, offering guidance on whether or not an IV-PO switch was appropriate. The reminder was displayed in the EHR from 60 hours onwards until a physician acknowledged the notification, or the IV therapy triggering the reminder was stopped. However, the reminder was automatically terminated 10 days after its appearance. These reminders were displayed in 12 divisions during the intervention period (year 2012). In contrast, no reminders were visible during the baseline period (year 2011) and in the control group (17 divisions). Comparisons of the durations of therapies were performed using the log-rank test. Levels of $p \leq 0.05$ were considered significant.

Results

A total of 22,863 IV antibiotic therapies were analyzed, and 6,082 (27%) were switched to PO. In the intervention group, 757 IV therapies were administered for a mean duration (±standard deviation) of 5.42 (±8.14) days before switching to PO in the baseline period and 794 courses for 4.47 (±5.49) days in the intervention period ($p=0.0035$), corresponding to a 17% reduction of the IV administration time. No significant decrease of the IV administration time was observed in the control group. The top five IV antibiotics that had been switched to PO were amoxicillin/enzyme inhibitor (EI), representing 45.5% of the switched IV therapies (most often switched to →PO amoxicillin/EI), piperacillin/EI (13.1%; →PO amoxicillin/EI), ceftriaxone (7.1%; →PO amoxicillin/EI), ciprofloxacin (5.7%; →PO ciprofloxacin), and cefuroxime (5.6%; →PO cefuroxime).

Discussion

The electronic reminders significantly reduced the time until switching from IV antibiotic therapies to the oral route of administration by 17%. They were triggered with a delay of 60h after onset of the IV treatment and only if some patient-specific conditions were met, in order to limit alert fatigue. As opposed to previous studies using paper-based interventions, this computer-based approach allows for a hospital-wide implementation with an open-end intervention period since no manpower is required for the continued operation of electronic reminders within the EHR.

Cardiorespiratory physiological data as an indicator of morphine pharmacokinetics and pharmacodynamics in critically ill newborn infants

Nadja Bressan, Ph.D. [1,2], Carolyn McGregor, Ph.D. [1], Andrew James, MBChB, MBI. [2,3]
[1]Faculty of Business and Information Technology, University of Ontario Institute of Technology, Oshawa, ON, Canada; [2]Division of Neonatology, The Hospital for Sick Children and [3]Department of Pediatrics, University of Toronto, Toronto, ON, Canada

Introduction

Morphine is a natural opioid that acts as an agonist at the mu and kappa receptors, which are receptors for analgesia and sedation. It is the commonest drug used for analgesia in newborn infants. Morphine pharmacokinetics and pharmacodynamics (PK/PD) in neonates are not well understood. The objective of this study is to use simulation software for the estimation of drug concentration and for the correlation of morphine concentration with heart rate variability.

Methods

Newborn infants admitted to the Neonatal Intensive Care Unit (NICU) at The Hospital for Sick Children who were enrolled in an institutional Research Ethics Board approved study of neonatal infection and received morphine for analgesia were enrolled in this study. A three compartmental model structure with a biophase was used to implement Krekels' model parameters for morphine[1]. The compartments were described in Krekels' thesis: concentration in a fourth compartment is used for correlation with heart rate variability (HRV) [2]. Four differential equations were modeled by state space approach. The bodyweight and clearances were calculated using an allometric equation with a scaling factor (K) of 1.44. The morphine constant infusion (ml/h) titrated to the premature infants was considered as the input of the PK model. The output of the discrete state space function is used to estimate concentrations every 10 seconds. This study considered gestational age (GA) and postnatal age (PNA) to establish the premature infant weight in the allometric equation to be used in the PK model as shown in Figure 1. PK model output, represented by morphine concentration (um/ml), was synchronized with physiological data acquired through the Artemis platform[3]. The PK algorithm was implemented using IBM's Infosphere Streams software together with Streams Processing Language (SPL) in Artemis as a sub-entity simulator. Artemis is a big data platform operational in the NICU at The Hospital for Sick Children since August 2009[2]. A biharmonic-type interpolation method was performed using MatLab® to solve a 3D scattered data interpolation problem considering morphine concentration, gestational age and HRV. Premature infants and extremely immature preterm were used to design the curve response and to validate the model. The total population was divided into two sub-groups with 12 subjects each, one to design and the second to validate the curve fitting.

Results

Twenty-four subjects, gestational age 24-41 completed weeks (mean ± SD: 33.25 ± 5.42) and birth weight 700-3300 grams (mean ± SD: 2440 ± 910), were studied under morphine concentrations at 100ug/ml, 80ug/ml, 40ug/ml, 20ug/ml. The results demonstrated that the morphine concentration estimated by Krekels' model correlates with heart rate variability for subjects in the gestational age range between 32 and 40 weeks. HRV presented a poor correlation with morphine concentration in subjects between 30 and 24 weeks, as shown in Figure 2. The design group presented a R^2=0.6251; the goodness of validation group presented a Sum of Squares Due to Error (SSE) = 824937.

Discussion

The correlation between drug concentration and heart rate may be considered as a pharmacodynamic marker for morphine in the neonatal population. The modeling of morphine PKPD for the neonatal population must be revisited to consider the immaturity of the newborn infant as indicated by gestational age. The PKPD models for the extremely immature preterm population may be improved through the inclusion of maturation as a covariant.

Evolving Collaboration Patterns in Medical Research

Jason Cory Brunson[1], Xiaoyan Wang[1,2], and Reinhard Laubenbacher[1]

[1]Center for Quantitative Medicine, University of Connecticut Health Center, Farmington, CT
[2]Department of Family Medicine, University of Connecticut Health Center, Farmington, CT

Abstract Bibliographic databases are a mainstay of scientometrics and social network analysis, yet an essential temporal network analysis of the enormous medical literature remains to be conducted. We employ graph-theoretic tools to capture the evolving structure of the medical research community across the 50 years of MEDLINE's existence. Early analysis reveals that the medical research community has undergone periods both of increasing and of decreasing collaboration and cohesion. This suggests the need to identify real-world influences and to understand the range of evolutionary behaviors and their influencing factors across subject- or institute-specific communities.

Introduction The structure of the medical literature provides an underutilized resource for identifying and evaluating research trends. Changes in this structure reflect changes in the practices, resources, and culture of the medical community. Our goal is to perform a comparative analysis of research initiatives and institutes, in order to identify key structural predictors for network outcomes such as the cohesion of communities and the emergence of specialized fields, and to link these predictors to real-world factors such as the funding of initiatives and the founding of institutes. We begin by investigating the structure and evolution of the aggregate medical literature in an historical context.

Methods Our data consist of all MEDLINE entries from 1964 to the present. We employ graph-theoretic models and diagnostics to study the aggregate medical research network as well as several subnetworks organized around specific research institutes or subject matters.

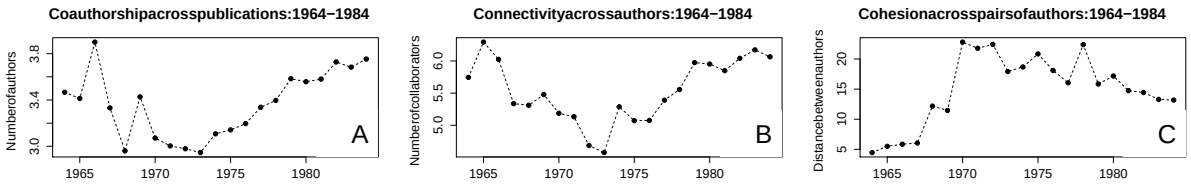

Figure 1: Time series across 1964–1984 for (A) mean coauthors per publication, (B) mean collaborators per author, and (C) mean number of coauthorships required to connect two authors.

Results Preliminary results reveal changing evolutionary behavior in the medical community. At MEDLINE's inception, the community was growing less collaborative, in terms of the typical number of authors on a paper and the number of collaborators of a typical author, and more dispersed, in terms of the 'distance' between authors through coauthorship (see Fig. 1). These trends reversed in the early 1970s, though other common diagnostics of network structure, such as triadic closure and homophily, remained steady. This suggests a profound shift on the way research was conducted between the late 1960s and the late 1970s. A thorough look at subject-specific or institute-specific communities, as well as sensitivity analysis on the whole, will bring this influence into sharper focus.

Discussion Our early results present two directions for further analysis: (1) to detect the effects on network evolution of funding initiatives, the founding of institutes, and other large-scale research-oriented programs, and (2) to understand how research communities organized around specific topics or hosted by specific institutes are distributed across the network diagnostic parameter space. We are currently pursuing both questions.

Assessment of Vital Sign Data Accuracy and Timeliness as Recorded in an EHR

Lorraine R. Buis, PhD,[1] Lisa Gulker, DNP, RN[2] Melissa Plegue, MA[1]

[1] University of Michigan, Department of Family Medicine, Ann Arbor, MI
[2] Applied Clinical Informatics, Tenet Healthcare Inc., Dallas, TX

Introduction: Patient vital signs are one of the most basic and important measurements used within the hospital setting, and vital sign monitoring is an essential component of quality patient care. Vital signs provide a picture of current patient health status, which can aid in treatment protocol decisions, and may lead to early identification for serious conditions such as sepsis, respiratory failure, and other shock states. In order for the algorithms used to predict clinical deterioration to be most effective, we assume that the vital sign data entered into the EHR is both accurate and timely. The goal of this study was to determine the accuracy and timeliness of vital sign data recorded in an EHR in an adult acute care setting.

Methods: We conducted a retrospective records analysis of all vital signs taken over a seven-day period in one acute care unit within a large, eight hospital Midwestern healthcare system. We compared data for seven different vital sign measurements (temperature, systolic blood pressure, diastolic blood pressure, respiratory rate, heart rate, SpO2, and patient self-reported pain scores) that were pulled directly from vital sign monitors each day, to data entered into the EHR. To determine accuracy, we looked for discrepancies between vital sign monitor and EHR data, and to determine timeliness, we compared timestamps from the vital sign monitor and the EHR.

Results: Our sample contained 728 sets of vital signs, from 85 unique patients. Of the seven vital signs captured by the vital sign monitors, for a variety of reasons, only about one-third to one-half of those taken by the vital sign monitor ultimately made it into the EHR. Pain scores were entered least frequently (34% of the time) and blood pressure was entered the most frequently (53% of the time for both systolic and diastolic). Of the measures which were entered into the EHR, error rates between vital sign monitor and EHR were less than 3% for systolic and diastolic blood pressure, as well as temperature. Pain scores had a slightly higher error rate (6%). Respiratory rate had an error rate of 11%, followed by SpO2 (15%). Pulse rate had the highest rate of error (24%), with nearly 1 in 4 pulse rates recorded in the EHR discrepant from what was recorded on the vital sign monitor. Regarding timeliness, on average, it took 49.7 (SD=59.04) minutes from the time vital signs were measured and assessed, to the time they were entered into the EHR. For approximately 15% of vital signs, 90 minutes or more passed from the time of assessment to entry into the EHR. Providers consistently underestimated their lag time from vital sign assessment to EHR entry by an average of 24.9 minutes (SD=60.45).

Discussion: Although the majority of vital signs had low error rates, discrepancies in pulse rate, respiratory rate and SpO2 were unacceptable from a clinical standpoint. Average lag times of nearly 50 minutes from vital sign assessment to EHR entry compromise the ability of healthcare providers to intervene early when clinical deterioration could be detected or predicted. Results from this investigation are essential for building the case for healthcare systems to move toward vital sign integration directly from vital sign monitors to EHR, without the need for human intervention, which may ultimately lead to improved quality of vital sign data and patient care.

Applied Clinical Informatics Best Practices in support of Clinical Next Best Practices: Integrating Knowledge Discovery to Delivery into Workflow

Matthew M. Burton, M.D.[1,2,3,4], David W. Larson, M.D., MBA[2,5], Jenna Lovely, PharmD, BCPS[2,6], Tim Miksch[4], Steve Peters, M.D.[4,7], Tim Larson, M.D.[4,8], John Wald, M.D.[9], Bruce Evans, M.D.[10]

Abstract

Consistently delivering Best Practice care to patients in an efficient, effective, and safe manner holds the most promise for transforming not only health care delivery, but the practice of medicine. However, standard use of Best Practice must not only apply to patient care processes, but to the means and mechanisms by which such clinical Best Practices are discovered, disseminated, delivered, and reinforced. Clinical Informatics and Engineering Best Practices further hold much promise to the optimal application of ever more complex and voluminous body of domain knowledge to similarly sophisticated patient information. This study demonstrates the potential for such an approach.

Introduction

Standardized clinical best practices, such as Enhanced Recovery Pathways for the postoperative inpatient setting, serve to ensure that the highest quality care is delivered consistently to achieve the best outcomes (clinical and utilization) in the most efficient and safe manner. Such standardization further lends itself to widely accepted clinical/ health services research as well as informatics, engineering, and management science approaches for continued optimization along all dimensions of quality (safety, timeliness, effectiveness, efficiency, patient-centeredness).

Consistent use of such standards must be integrated into clinician workflows and mental models such that they are easy and intuitive and that deviation from such a standard is obvious, assessable, and actionable. Furthermore, the discovery and rapid integration of newly recognized best practices must be similarly integrated into optimal workflows facilitated through best practice means (processes) and mechanisms (information and knowledge management tools) often co-redesigned. Such an endeavor of continually delivering the very 'next' best practice through effective, efficient, and sustainable means necessitates adherence to likewise advanced best practice health system engineering and applied clinical informatics principles, approaches, and tools.

Methods

For this study, we first employed a mixed-method approach to capturing clinical workflow including mental models and information flow to define the information and knowledge management needs of an academic surgical practice. These methods include semi-structured interviews, flow mapping, direct observation, screen capture, behavioral and cognitive task analysis, and electronic information mining (event logs, report generation). Next, we conducted iterative prototyping and in-situ testing using user experience design methods to design analytics, practice management dashboards, and mobile point of care tools. Lastly, we implemented these designs through Agile software development using various software architecture and medical informatics best practices (SOA, stateful knowledge representation, and standardized terminologies and information models). Study design was a nested, interrupted time-series.

Results

Key clinical workflows and clinician mental models were identified and supporting processes and tools were co-redesigned for optimal performance. Surgical Complications, Utilization (LOS), Time-on-task, and Mental Workload were all significantly reduced while Pathway Compliance was sustained.

Conclusion

We have demonstrated a sustainable, transferable, and diffusible health systems engineering and applied clinical informatics approach to optimally delivering 'next' best practice clinical pathways. We have further extended the principle of standardization on best practice for clinical pathways to the supporting or enabling engineering, informatics, and redesign principles, methods, and tools. We have leveraged informatics and software development best practices for scalable, extensible infrastructure such that these informatics interventions can be sustained, transferred to additional clinical domains, and more broadly disseminated. We have broadly applied process reengineering best practices to eliminate waste in the practice of academic medicine (surgery) in support of knowledge work- from discovery to delivery.

Introduction

Rheumatoid arthritis (RA) is a chronic, debilitating disease with significant morbidity and mortality. The American College of Rheumatology (ACR) guidelines for treatment of RA include the early use of anti-TNF medications in cases that do not respond to methotrexate or other non-biologic combination regimens[1]. Anti-TNF treatment is expensive, is contraindicated in cases of infections due to the immune modification, and is not always efficacious. Determining the genetic predictors of response and helping elucidate the biology of response are factors important to improving treatment options.

Methods

We identified 141 individuals with a confirmed clinical diagnosis of RA and anti-TNF medication mentions in their clinical documentation from Vanderbilt's Synthetic Derivative, a de-identified image of the EHR linked to the BioVU DNA repository[2]. Clinician review confirmed 103 individuals were administered anti-TNFs. Twenty confirmed individuals were randomly selected for review by a second clinician. The kappa was 0.56 (across response and non-response for three drugs); the disagreements were resolved and improved future review guidelines. To select more charts for review, we identified a threshold of etanercept (Enbrel) mentions from our initial reviews to yield a PPV>98% for true drug exposure. We applied a previously published algorithm for RA case identification and the etanercept mention threshold to select more charts for review. A subset of records was then reviewed by three rheumatologists to determine if they were responders, non-responders, or of indeterminate response to anti-TNF therapy. Individuals were considered responders if there was evidence for response at 6 months after initial treatment. However, if the individual appeared to no longer respond at 12 months, they were labeled a non-responder. A change in patient status indicating non-response after a 12 month period was considered a responder, but flagged with a "fade" effect. In addition, we included those individuals whose response was unsure as "unsure". Kappa was 0.53 over 20 charts shared between two reviewers. We applied a Support Vector Machine (SVM) that used n-grams (up to 5-grams) in a window up to 20 words before and after the drug mentions to predict response. We evaluated the algorithm using 5-fold cross validation. We further expanded our case and control set for the genetic and PheWAS by applying the predictive model to those individuals not reviewed to expand our case and control set. After identifying responders and non-responders, we applied the phenome-wide association study (PheWAS) method to identify clinical phenotypes associated with drug non-response[3]. The results of the PheWAS were used to inform a targeted genetic analysis.

Results

358 total etanercept treated individuals were reviewed in total with 231 responders, 68 non-responders, and 59 of uncertain response. The SVM had an area under the receiver operator characteristic curve of 0.88. The PheWAS identified four associations at a nominal p of 0.01, including degenerative disc disorders, which were disproportionately represented in the non-responding individuals. As axial skeleton involvement is more common in diseases such as ankylosing spondylitis and psoriatic arthritis, which are more commonly associated with *HLA-B27* positivity, we investigated genetic loci on chromosome 6 near the *HLA* and *TNF* genes[4]. We found a number of SNPs in this region associated, including rs13202464 (odds ratio=3.08, p=0.0008). This SNP is known to tag *HLA-B27*. See Figure 1 and Tables 1 and 2 for more results.

Discussion

We developed and coupled phenotype algorithms to identify a pharmacogenetic trait of drug efficacy: specifically, RA patients that responded and failed to respond to anti-TNF therapy. Using PheWAS, we identified clinical associations differentiating these two groups of RA patients, and genetic analysis suggests that non-responders are much more likely to have risk HLA-B27 variants by virtue of this tag SNP. Thus, these results suggest that underlying RA subphenotypes may be responsible for difference in drug response rather than factors more directly related to drug metabolism. Use of PheWAS to identify comorbidities associated with drug efficacy may assist in redefining disease toward a vision of precision medicine.

Hispanic Patients' Role Preferences in Primary Care Treatment Decision Making

Kenrick Cato, RN, PhD [1], Suzanne Bakken, RN, PhD[1,2]

[1]School of Nursing and [2]Department of Biomedical Informatics, Columbia University, New York, NY

Introduction

Shared decision making (SDM) is considered to be a crucial component of high quality and safe patient-centered primary care treatment[1]. Hispanics are the fastest growing minority group in the United States[2] and they experience substantial health disparities[3]. The aim of this study was to examine the factors that correlate with Hispanics' decision role preferences for participation in treatment decision making with their primary care clinician.

Methods

Hispanic patients (n=772) were recruited from five zip codes in the Washington Heights/Inwood community of New York City and survey data were collected via interview by bilingual community health workers in four New York-Presbyterian Ambulatory Care Network clinics. Data were analyzed using multinomial logistic regression to investigate the association between sociodemographic and health factors and role preference (Control Preference Score) [4] in primary care treatment decision making (passive, shared, active); passive role as the reference range.

Results

Most survey respondents preferred to participate in medical treatment decisions in a shared or active role (90%) and also had inadequate health literacy (95%). The odds of wanting to participate in decision making in a shared role with a primary care provider significantly increased with younger age (OR=0.98, 95% CI [0.96- 0.99], p =0.01), less than 21 years living in the United States (OR=0.48, 95% CI [0.27- 0.88], p =0.02), more adequate health literacy (Newest Vital Sign) (OR=.46, 95% CI [0.25- 0.83], p =0.01), better ability to understand health instructions, pamphlets or written health materials (OR=0.55, 95% CI [0.31- 0.99], p =0.05), and higher social role performance (OR=0.97, 95% CI [0.94- 0.99], p =0.04). Statistically significant odds for preference for an active role were higher education (OR=3.11, 95% CI [1.20- 8.04], p =.02), less than 21 years living in the United States (OR=0.37, 95% CI [0.19- 0.73], p =0.004), and younger age (OR=0.98, 95% CI [0.95- 0.99], p =0.02). However, the overall models demonstrated poor fit with study data explaining 10% -14% of the variation of the dependent variable.

Conclusion

Our analysis suggested a number of patient specific factors that should inform future informatics interventions related to Hispanic patients' SDM with their primary care clinician. This study confirmed the influence of age, depression, years lived in the United States and education on treatment decision control preference for Hispanics. Furthermore, the relationship between variables investigated in our study and their relationship to desired role in SDM for Hispanic primary care patients can be utilized by informatics tools in a number of ways: 1) to customize the user experience. 2) To target sub-populations of patients. For example, since while taking all other variables into consideration, age and education level are strongly correlated SDM, one might design a tool that solicits involvement in treatment decisions in a different way than you might from older, less educated patients. 3) To screen and validate patient SDM role preference. 4) To promote SDM, by providing tailored treatment decision aids to Hispanic primary care patients. In other words, utilizing patient level variables to customize the content of decision aids.

Next-Generation Terminology Requirements for Interprofessional Care Planning

Sarah Collins, RN, PhD[1,2,3], Kira Tsivkin[1], Stephanie Klinkenberg-Ramirez[1], Dina Iskhakova[1], Hari Nandigam MD, MSHI[1], Perry L. Mar, PhD[1,2,3], Roberto A. Rocha MD, PhD[1,2,3]

[1]Partners HealthCare System; [2]Brigham and Women's Hospital; [3]Harvard Medical School

Abstract

Team-based interprofessional care planning is associated with better care coordination and patient outcomes; yet, known terminology management infrastructures within electronic health records (EHRs) do not support sociotechnical requirements such as linking and sharing documented concepts among various professionals. This study, which will be complete in August 2014, is conceptualizing, developing, and evaluating next-generation approaches to terminology management for interprofessional care planning based on clinician-validated care planning scenarios. We will present our derived set of terminology-specific requirements and standards-based terminology model for coordinated team-based care, knowledge development of process-outcome associations, clinical decision support, and a learning health system based on validated clinical care planning scenarios.

Introduction

EHR terminology infrastructures are typically based on requirements of one profession, using one terminology, with few linkages between concepts. The requirements for interprofessional care planning will expand exponentially for EHRs shared by teams comprised of multiple health professions with overlapping terminology needs. The collaborative and cooperative activity of documenting on a shared care plan introduces interesting dynamics and opportunity and will require "smarter systems" that enable reconciliation of multiple plans of care and treatment plans into a patient centered and longitudinal care plan.[1,2] This study defined requirements and developed a proposed next-generation terminology model for patient-centered interprofessional care planning.

Methods

We developed interprofessional care planning scenarios for validation by an interprofessional panel of subject matter experts (SMEs) from primary, long-term, acute, and critical care. Six clinical scenarios were related to primary care for diabetes, depression and renal failure; episodic care for acute asthma; and critical care for oncology. We refined our conceptual model[3], defined requirements and analyzed terminology management approaches. We developed an information model using Object-Role Modeling (ORM) language that was aligned with HL7 Care Plan Domain Analysis Model. Next we defined a terminology management model that leveraged SNOMED CT and other standard terminologies. The model is being validated against a second set of scenarios and will be presented.

Results

Terminology model requirements with examples derived from clinical scenarios validated by SMEs representing medicine, nursing, pharmacy, social work, care coordination and specialty areas will be described. Requirements include: 1) high level categorization scheme of concerns, goals, and interventions (see Figure 2); 2) sets of profession-specific concerns and interventions (e.g., Primary Care Provider concern of 'uncontrolled type I diabetes mellitus' and Care Coordinator concern of 'patient has deficient knowledge related to glycemic control'); 3) sets of shared patient goals and sub-goals (e.g., 'gain glycemic control' -> 'eat a more nutritious diet' -> 'post-prandial blood glucose of less than 180'); 4) modifiers for goals to capture evaluation toward goal achievement (e.g., 'met', 'not met', 'in progress'); 5) semantic linkages between categories and across clinical concepts and professions (see Figure 2), 6) modifiers for concerns and interventions to communicate decision rationales and anticipatory guidance among the care team in the context of shared care plan documentation (e.g. 'referral to pharmacist to understand any reasons for lack of medication adherence and for medication education').

Conclusion

We identified a set of requirements and a terminology model for interprofessional care planning. The linkages of concepts to meet clinician validated care planning scenarios confirm a need for a "next-generation" terminology modeling approach. Future work should focus on extending and validating our terminology model.

Not Just For The Millennials: A Cross-Sectional Analysis Of Secure Messaging Use Among Elders, Families, And Physicians

BH Crotty MD MPH[1], J O'Brien BS[1], M Dierks MD[1], X Lu BS[1], H Feldman MD[1], C Safran MD MS[1]
Division of Clinical Informatics, Beth Israel Deaconess Medical Center

Learning Objectives

1. To determine how elders (≥75 years of age) and families use secure messaging to communicate with their physician

Introduction

As our population ages, patients, families, and caregivers will need an increasingly diverse set of tools for collaboration and coordination of geriatric care. In recent years, secure messaging through patient web portals has become available, but little is known about how elderly patients and their families use the tool.

In this study, we sought to assess trends in the use of secure messaging with providers via a patient portal among patients aged 75 years and over. Additionally, we performed a content analysis to characterize the reasons why patients might be using secure messaging, and to determine if family members also used the portal to communicate with providers.

Methods

This was a retrospective review of secure messaging data sent via the Beth Israel Deaconess Medical Center's patient portal during the period from 2005 to 2010, with chart review of a random sample of messages from 2010. In the first analysis, we obtained and analyzed utilization data from the secure messaging feature of the patient portal on all patients who were registered users of the patient portal, stratifying by age. Each secure message was considered a distinct evaluable event. In the second analysis, we randomly selected 60 messages from unique patients who were users of the messaging feature during 2010. We reviewed the content of each message, categorizing it into one of ten non-mutually exclusive categories, and ascertained whether the sender was the patient or a family member. Concurrently, we reviewed the clinical record determine if the message coincided with any recent ambulatory visits.

Results

In 2010, patients 75+ accounted for 6.1% of all registered patients. Of messages sent by patients to physicians, the percent sent by or on behalf of patients over the age of 75 increased from 2% in 2005 to 5% in 2010, where 541 unique patients sent a total of 4064 messages. Nearly all messages (98%) were sent to primary care providers. Patients sent 85% of messages, while individuals who identified themselves in the message as an informal caregiver of the patient sent 15% of messages from a given patient's account (of these, adult children of the registered patient accounted for 78%). One-third of messages were within 15 days of a visit to the physician receiving the message, and 12% were within 15 days of an emergency room visit. Messages were mostly for medication management (27%), results management (25%), to discuss a clinical concern (23%), or for coordination of care (18%). We found no significant differences comparing messages sent by patients and by family members.

Conclusions

Elderly patients are increasingly using secure messaging, though they still account for a relatively low percentage of total messages. Caregivers, mostly adult children, accounted for 15% of all messages, and appear to use the secure messaging for care coordination and visit follow-up. This suggests a need to develop more robust methods for proxy access for patient caregivers. Notably, questions about coordination of care accounted for nearly one in five messages. As elders age and families take on more caregiving and coordination, asynchronous messaging may play an important role in meeting communication and information needs.

Table: Message content according to the sender in a sample of 60 randomly selected messages. Messages were assigned non-mutually exclusive categories. All messages came from the patient's account.

Message Content	Sent By Patient (n=51)	Sent By Family (n=9)	Overall (n=60)
General Health Question	10%	11%	10%
Coordination of Care	16%	33%	18%
Clinical Concern	24%	22%	23%
Social Concern	2%	0%	2%
Psychiatric Concern	11%	2%	3%
Clinical Update	12%	22%	13%
Visit Follow-Up	2%	22%	5%
Results Management	24%	33%	25%
Healthcare Finances	6%	0%	5%
Medication Management	29%	11%	27%

Engaging Patients, Providers, and Institutional Stakeholders in Developing a Patient-centered Microblog

Anuj K Dalal, MD[1,2] Patricia Dykes, RN, DNSc,[1,2] Kelly McNally,[1] Diana Stade,[1] Kumiko Ohashi, PhD, RN,[1] Sarah Collins, PhD, RN,[1,2] David W Bates, MD, MSc,[1,2] Jeff Schnipper, MD, MPH[1,2]

[1]Brigham and Women's Hospital, Boston, MA, [2]Harvard Medical School, Boston, MA

Introduction: Care team communication in acute care settings is fragmented, inefficient, and frustrating.[1, 2] Providers share clinical impressions, opinions, and knowledge informally. Patients clamor for seamless communication with their providers.[3] More efficient management of the informal dialog among patients, inpatient and ambulatory providers during hospitalization is necessary to develop a collaborative and meaningful, patient-centered plan of care. Hospitals require a unified approach to reconciling the informal conversations that occur in text pages, emails, and in some instances, unsecure text messages, to coordinate care more effectively. Web-based tools such as microblogs could facilitate seamless communication and collaboration among patients and providers, but introducing a potentially disruptive technology is not without challenges. Often developers do not engage stakeholders and potential users during the development process – this may limit adoption.[4] The purpose of this study is to describe our experience at engaging patients, providers, and institutional stakeholders in the development of a patient-centered microblog, a single platform where patients and providers can communicate and collaborate.

Methods: This study took place at a large academic medical center in Boston, Massachusetts. We adapted AHRQ's Guide to Patient and Family Engagement in Safety and Quality to serve as a conceptual model to involve patients, providers, and institutional stakeholders in the design and development of our patient-centered microblog (Figure 1). We conducted a total of 10 patient interviews (2 patient advocates, 8 patients), 3 focus groups of 4-6 providers each (physician assistants, interns, residents, attendings, nurses), and 8 interviews of *institutional stakeholders* (2 clinical directors, 2 nursing unit directors, 2 clinical informatics leaders, director of our Center for Patient and Family Relations, and general medicine residency program director) lasting up to 1 hour. The following categories were addressed: potential uses of the microblog, care team member identification/role assignment, clinical workflow, alert fatigue, attitudes and emotions, and medical-legal ramifications. Participants were encouraged to provide feedback regarding the engagement process. We used content analysis methods to interpret descriptive data from focus groups and interviews, and a 2-person consensus approach to identify major themes.

Results: Descriptive feedback and derived themes by type of forum are presented in Table 1. In general, we found a high degree of enthusiasm and support among patients, providers, and institutional stakeholders for using the patient-centered microblog as a platform to get patients and providers "on-the-same-page" with regard to the patient's plan of care but this was tempered by patient, provider, and institutional stakeholder concerns. Specifically, these include providing access to designated caregivers, managing notification settings, integrating into clinical workflow access points, responsibility for managing microblog conversations, providing appropriate context for use, managing patient and provider expectations regarding timing of responses, and addressing medico-legal considerations with regard to patient-provider messaging. Finally, we received positive feedback with regard to our engagement process. All provider participants expressed willingness to participate in our planned pilot (Box 1).

Conclusion: Overall, our experience at engaging patients, providers, and institutional stakeholders during the design and development of a potentially disruptive technology was positive. Although providers and stakeholders were enthusiastic about the idea of using the patient-centered microblog in the acute care setting, they expressed a moderate level of concern with regard to actually using it. Our next steps are to pilot test, iteratively refine, implement, and formally evaluate the patient-centered microblog in the acute care setting.

Table 1. Design and Development of a Patient-Centered Microblog: Major Themes from Focus Groups and Individual Interviews by Type of Forum

Type of Forum	Feedback from Focus Groups & Interviews	Themes
Patients[*]	• Useful for asking questions related to the plan of care (goals, problems, schedule) that arise after rounds or which they forget to ask during rounds • Providing access to more "tech-savvy" caregivers, especially for elderly, disabled, less activated patients; engaging caregiver in general • Requires a method of easily identifying name and role of each provider • Useful for scheduling and coordinating patient/caregiver/provider meetings • Expressed apprehension about overburdening physicians with messages	High degree of patient/caregiver enthusiasm for messaging directly with providers outside of rounds and face-to-face visits. For less "tech-savvy" patients, designating family caregiver access would be useful
Providers[†]	• Useful for coordinating care among non-localized, ambulatory and sub-specialty providers • Message "read receipt" and acknowledgment functionality would be useful • Access to tool should not be a separate workflow • Uniformly concerned regarding notification overload → requested user-configurable notifications settings (e.g., email, mobile "app" push notification) • Uniformly concerned that use of instant messaging tools by patients would encourage the expectation of a "real-time" response; expressed concern regarding potential abuse of tool (e.g., overburdening providers regarding "trivial" concerns) • Expressed apprehension regarding notifications from microblog, email, pagers, etc.; concern with regard to missing important patient messages • No one wants to take responsibility for "owning" the microblog conversations • Expressed interest in reviewing patient messages before rounds as it would help guide face-to-face discussions with patients/caregivers (especially for questions that come up after rounds)	High degree of enthusiasm for using the microblog to facilitate transparency of informal patient-specific dialog among providers was tempered with concerns related to notifications, workflow integration, responsibility for managing the microblog, and perception of being required to respond to all patient messages in real-time
Institutional Stakeholders[‡]	• Useful to coordinate care for patient populations at high risk for readmissions • Limit scope to patient-specific, clinical messaging • Clearly distinguishing patient from provider conversation threads → patient-provider messaging should be treated similar to current patient-portal messaging but provider-only conversations should remain informal • Limit context to plan of care and goals of care discussions • Access for family caregivers crucial when patients do not have capacity, but this may be challenging • Responsibility for managing care team role assignment and microblog conversations is murky • Uncertainty with regard to keep it separate from medical record • Managing expectations for patient and provider messaging is needed	High degree of enthusiasm for coordinating care across care settings was tempered by need to manage patient and provider expectations for use, providing appropriate context and scope for use, delineating responsibility for managing microblog conversations, challenge of providing access to family caregivers, and mitigating legal concerns regarding informal and formal microblog conversations

Box 1. Comments from focus group participants

> "We are so appreciative to be included in a proactive manner and to feel heard. Thank YOU for working on quality improvement projects that will hopefully improve our systems and patient care/satisfaction."
>
> "Though our feedback may sound pessimistic, I think we are all in support of the overall goal/big picture and just want to ensure we bring up concerns early so that any that can be addressed/modified will be to help ensure later success."

A smart suite for the evaluation of data generated by a smartphone application for nutritional triage in oncological outpatients

Abstract

Backgrounds and objectives: *Weight loss in cancer patients is common because of the disease itself and the anti-cancer treatment [1], and is significantly related to various negative effects on patient health and recovery, e.g., worse clinical outcome, poor tolerance of anti-cancer treatment, reduced quality of life and increased mortality [2-4]. Unfortunately, nutritional deterioration and weight loss often go unrecognized, and when recognized are often accepted by patients and caregivers as unmodifiable, while nutrition therapy could be used to improve nutritional status and slow down the process of nutritional deterioration. Our objective was to create a clinical decision support system that uses data generated by a smartphone application for nutritional triage in oncological outpatients to detect nutritional deterioration and enable interventions by physicians and nutritional experts.*

Methods: *To gather feedback on a patient's perceived quality of life and nutritional status, we created an android smartphone application that presents a set of questions to a patient on a daily basis, and an interface in the hospital information system to present those data to the physicians. To estimate the perceived quality of life, we incorporated the European Organization for Research and Treatment of Cancer (EORTC) QLQ-C30 survey, basic model [5]; the scored Patient-Generated Subjective Global Assessment (PG-SGA) was used to detect malnutrition [6]. We used a sample of ten patients from an ongoing clinical study to evaluate the usability and additional medical value of the application. Patients included in this study had to be oncological patients with solid tumors (lung, ear-nose-throat, or gastrointestinal tumors), age 18 or older, receive ambulatory anti-cancer treatment as outpatient for at least a month, and had to have access to a smartphone and wireless internet connection, as well as weighing scales. Patients with a life-expectancy of less than six months were excluded.*

Results: *Questions from both questionnaires were combined into a single questionnaire comprising 34 questions. These questions were divided by theme into eleven categories i.e., Weight, Food 1-2, Function 1-3, Daily life 1-3, Quality of Life and Medical visits. The collected data were forwarded to the hospital information system where they were available to physicians; The data displayed included the native scoring mechanisms of QLQ-C30 and PG-SGA were used to indicate a patient's health status or performance in each of these categories. Based on the combined PG-SGA and QLQ-C30 scores, the physicians are able to make more accurate nutritional triage recommendations. Furthermore, the usability study showed that 90% of all patients found the application easy to use and handle, and were of the opinion that it had a good additional medical value; 40% felt it influenced their daily lives and awareness.*

Discussion: *We presented a smartphone application and the integration of generated data in medical routine for oncological outpatients to keep an accurate record of their nutritional status and perceived quality of life. At present, the smartphone application is used in a clinical trial involving 30 patients, and the routine integration is still being extended as more data comes in. Patients indicated that they were generally satisfied with the smartphone application, and using smartphones as a method to monitor their health. Currently we are also working with nutritional experts to develop a rule-based system for the generation of nutritional alerts and interventions, and to add an epidemiological module in order to analyze the entire patient population.*

HARVEST, a Holistic Patient Record Summarizer at the Point of Care

Noémie Elhadad, PhD[1], Sharon Lipsky Gorman, MA[1], Jamie S. Hirsch, MD, MS[1], Connie Liu, MS[1], David K. Vawdrey, PhD[1], Marc Sturm[2]
[1]Columbia University, New York, NY; [2]NewYork-Presbyterian Hospital, New York, NY

Introduction

In many care settings, clinicians are faced with an overwhelming amount of complex information about their patients, with little time for chart review [1]. Failure to digest patient data may result in errors in diagnosis and delayed care [2,3]. The need for better health information management and visualization tools has long been recognized [4,5], yet current electronic health records (EHRs) do not yet provide the cognitive support necessary for effectively and efficiently reviewing patient data. EHR displays are plagued by low information content, do not honor established interface design principles, and cannot be readily customized without imposing a considerable burden on clinicians and information technology professionals [6,7]. Important research has been undertaken on visualization of patient histories [8–10] and domain-specific summarizers [11], motivating our hypothesis that a holistic patient-record summarizer can impact care in a beneficial fashion. In this abstract, we describe the design, implementation, and deployment of HARVEST, a longitudinal patient record summarization system.

Methods

HARVEST is an interactive, problem-oriented patient record summarization system (see Figure below) [12]. The summarizer differs from previous work in three critical ways: (i) it extracts content from the patient notes, where key clinical information resides; (ii) it aggregates and presents information from multiple care settings, including inpatient, ambulatory, and emergency department encounters; and (iii) it is integrated into two commercial EHR systems, and is available for all patients in our institution, not just a curated dataset or for specific patient cohorts.

The natural language processing (NLP) of clinical notes is carried out through a named-entity recognition system that indexes concept mentions. Because HARVEST aggregates problems, NLP was constrained to extracting concepts from the UMLS semantic group "Disorder" only, restricted to the SNOMED-CT Core Problem List. Concept salience weights are computed dynamically to reflect both the frequency of the concept in the patient notes in a given time slice of the record, and the prevalence of the concept across all patients in the institution. To enable parsing and salience computation at scale, we created a distributed computing infrastructure (using Apache Hadoop) and implemented a map-reduce version of our NLP system to parse the notes from a variety of HL7 interface feeds.

Results

The Hadoop infrastructure enabled us to accommodate the large volume of clinical documents generated in our institution (650,000 notes per month): a small four-node cluster processed 20,000 notes/second compared to 500 notes/second in a non-distributed computing environment. The infrastructure also permitted us to experiment with different parsing and salience computation strategies through short development cycles.

HARVEST was deployed within NewYork-Presbyterian's iNYP clinical information review system as a beta release in September 2013. As a first phase of deployment and to study the impact of HARVEST on clinical care, access was limited to internal medicine residents and residents and attending physicians in the emergency department (ED). Three primary use cases for the summarizer have emerged thus far: (i) in the ED, as a way to capture the essential knowledge about a patient's history in an efficient fashion, including previous emergency visits and patterns of visits; (ii) in internal medicine, as a support tool for performing an in-depth patient chart review before admitting a patient to the hospital; and (iii) in the primary care clinic, for chief residents as an education tool during precepting hours with residents.

Discussion

HARVEST addresses an unmet need for clinicians at the point of care, facilitating effective and efficient review of essential patient information. The deployment of HARVEST in our institution allows us to study patient record summarization as an informatics intervention in a real-world setting. It also provides an opportunity to learn how clinicians use the summarizer, enabling informed interface and content iteration and optimization to improve patient care. Future work includes customizing the content selected by HARVEST for different types of clinicians.

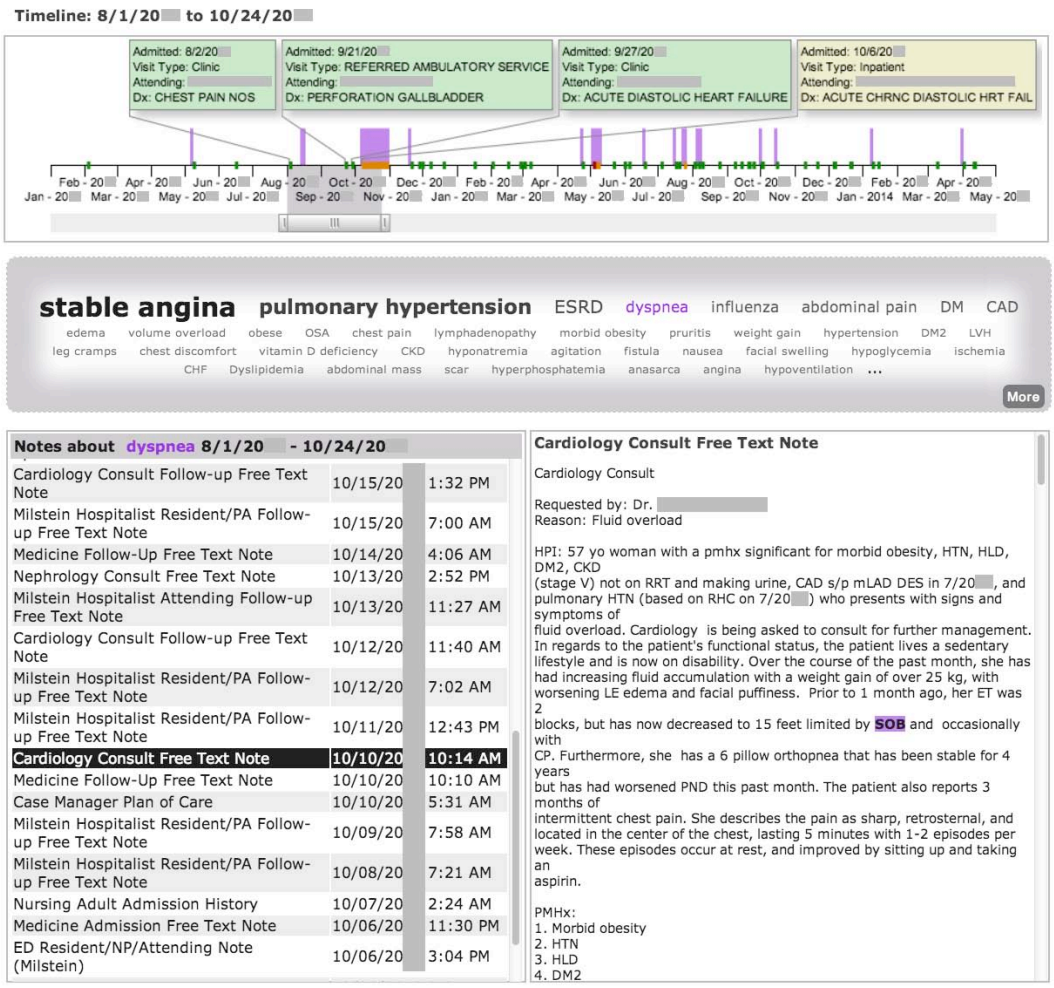

Figure 1. De-identified HARVEST screenshot for a sample patient, part of iNYP. For the selected time range (3 months), stable angina, pulmonary hypertension, end-stage renal disease, and dyspnea are the most prominently documented problems. HARVEST also identified diabetes mellitus, hypertension, and dyslipidemia as important problems. The problem "dyspnea" was selected. The Notes panel lists all notes in the selected time range that mention this problem. A cardiology consult note is selected and displayed in the lower right panel, with all mentions of dyspnea (and synonyms) highlighted. On the timeline, documentation of dyspnea is highlighted by purple bars, indicating that dyspnea was a particularly salient issue at that time, as well as 6 months later.

Designing Specific Alerts for Potassium-Increasing Drug-Drug Interactions

Emmanuel Eschmann, MD, Patrick E. Beeler, MD, Jürg Blaser, PhD
Research Center for Medical Informatics, University Hospital, Zurich, Switzerland

Abstract: *Electronic warnings against hyperkalemia during potassium-increasing drug-drug interactions (DDIs) are often overridden due to their low specificity. The treatments of 76,467 inpatients were analyzed to design more specific alerts. Unnecessary alerts may be suppressed at onset of DDI by considering the most recent serum potassium level or additional patient parameters. However, short-term forecasts based on the periodically monitored serum potassium level achieve the highest specificity compared to an initial prediction for the entire DDI period.*

Introduction: The warnings against hyperkalemia (serum potassium [K^+] ≥5.5mEq/l) triggered during K^+-increasing drug-drug interactions (DDIs) are often ignored due to their low specificity and might therefore induce alert fatigue. This retrospective analysis aimed at the development of highly specific alerts. The impact of the novel alerting concept will be assessed in a prospective clinical trial.

Methods: The data of all inpatients admitted to the University Hospital Zurich during a 25 months period were included, except for ICU stays. The K^+-increasing DDIs were identified using the knowledge base hospINDEX (distributed by e-mediat AG, Switzerland). Only the DDIs with the highest severity levels "contraindicated" and "monitoring or adaptation required" were considered. Generalized additive models were used to identify important patient parameters. The efficacy of the models to detect those DDIs likely to induce hyperkalemia was retrospectively validated. The alert thresholds were defined by applying Youden's J statistic on ROC curves, using 50% of the data as the calibration set and 50% as the validation set. ROC curves were compared with Delong's test.

Results: We analyzed 1.5 million drug orders of 76,467 patients and identified 8,431 K^+-increasing DDIs (mean duration 6.4 days) which induced 151 hyperkalemias. Tab. 1 compares common (A_{none}, A_{K+}) and novel alerts (A_{opt}, B_{K+}, B_{opt}). The A-alert rules (A_{none}, A_{K+}, A_{opt}) were applied at onset of each K^+-increasing DDI: A_{none} considered no patient parameters, A_{K+} took into account the serum K^+ level at onset of DDI, and A_{opt} included 8 additional patient parameters. In contrast, the B-alert rules (B_{K+}, B_{opt}) were applied not only at onset of the DDI, but again for each serum K^+ level obtained during the DDI: B_{K+} considered merely the current serum K^+ level, whereas B_{opt} additionally included 10 patient parameters.

Table 1. Comparison of 5 alerting concepts.

Triggering event	Warnings against	Label	Parameters considered	Sensitivity	Specificity
start of DDI	risk for hyperkalemia during the entire period of DDI	A_{none}	none	100.0%	0.0%
		A_{K+}	last serum K^+ before onset of DDI ≥4.2mEq/l	54.8%	68.6%
		A_{opt}	9 patient parameters	59.4%	71.6%
start of DDI and each serum K^+ measurement during DDI	risk for hyperkalemia within the next 48h	B_{K+}	current serum K^+ ≥4.4mEq/l	70.5%	76.5%
		B_{opt}	11 patient parameters	75.6%	72.4%

Compared to the systematic warnings at onset of each K^+-increasing DDI (A_{none}), the concept A_{K+} increased the specificity but decreased the sensitivity by restricting the alerts to K^+ levels ≥4.2 mEq/l. The proposed novel alerts A_{opt}, B_{K+} and B_{opt} provided enhanced sensitivity and specificity compared to A_{K+}: Including 8 patient parameters in addition to the most recent serum K^+ level significantly improved the alert effectiveness (A_{opt} vs. A_{K+}; Delong's test: $p=0.024$). Focusing on short-term predictions of hyperkalemia occurring within the next 48h further increased both sensitivity and specificity (B_{K+} vs. any A-alert; $p<0.05$). However, including additional patient parameters did not significantly improve sensitivity and specifity (B_{opt} vs. B_{K+}; $p=0.056$).

Discussion: The effectiveness of alerts could be improved stepwise, (i) by considering the most recent serum K^+ level at onset of DDI, (ii) by including additional patient parameters, and (iii) by considering 48h forecasts instead of predictions for the entire DDI-period. Thus, focusing on short-term predictions of the risk for hyperkalemia based on serum K^+ monitoring improves the alert specificity. An ongoing randomized clinical trial will assess whether this novel concept reduces alert fatigue and increases patient safety.

Automated Detection of Early Physiological Deterioration in Hospitalized Patients

Introduction: The average age of the US population is increasing as is the complexity of their medical care. As a result, up to 5% of patients experience physiologic deterioration (PD) during their hospital stay resulting in admission to the intensive care unit (ICU) or death[1, 2]. Studies reveal that many of these adverse events are preceded by indicators of PD[3-11]. Medical emergency teams (MET) were developed to prevent patient crisis before a cardiopulmonary arrest [12]. However, delayed MET calls are common and patients who are attended to within 30-60 minutes of PD have significantly lower mortality rates [8, 13, 14]. Therefore, to be effective, MET must have an afferent limb (case detection and response triggering) in addition to an efferent limb (medical response)[15].

Methods: We created a MET Risk committee comprised of critical care nurses from the MET and its nursing and medical directors, intensive care physicians, an infectious disease physician and medical informaticists. A decision support tool was developed which monitored hospitalized patients every 5 minutes and used vital sign and neurologic data in our electronic medical record (EMR) to identify patients with early PD. Once the positive predictive value (PPV) of our PD alert model was acceptable, we went live on a 33-bed medical and oncology floor (A) and a 33-bed non-ICU surgical trauma floor (B). During the intervention year, pager alerts of early PD were sent automatically to charge nurses along with access to a graphical point-of-care web page to help facilitate patient evaluation. Nurses were requested to fill out a form describing the validity of and their response to the PD alerts.

Results: Patients on unit A were significantly older and had significantly more comorbidities than unit B. During the intervention year, unit A patients had a significant increase in length of stay and total hospital cost, an increase in ICU transfers ICU 163 (5.1%) of 3189 compared to 146 (4.3%) of 3423 ($p = 0.1163$), significantly more MET calls (60 vs 29, $p = 0.0004$) and significantly fewer patients died (84 (2.6%) vs 125 (3.7%), $p = 0.022$) compared to the pre-intervention year. No significant differences in outcome were found on unit B and no differences between pre-intervention and intervention patient populations were found in either unit. Nurses called a physician based on 51% and 44% of the PD alerts in units A and B and interventions were initiated based on 59% and 52% of the PD alerts.

Discussion: There is variability in the ability of healthcare to detect patients who experience PD[16]. We report the results of a four year effort to use our EMR to develop, implement and evaluate an automated case detection and response triggering system for PD that meets nursing workflow and endorsement. Nurses on both study units reported an appreciated difference in their workflow based on the early identification of patients with PD. This study found use of computerized decision support provided a way to constantly monitor patients and notify nursing of early PD which resulted in a significant increase in appropriate MET calls and a significant decrease in mortality in the nursing unit containing older patients with multiple comorbidities. Moreover, with the patient trending information contained in the graphical alerts, nurses reported they had the information they needed to evaluate the patient status, felt more confident about their assessment, and were more at ease about requesting additional help.

RexMart: An Open Source Tool for Exploring and Sharing Research Data without Compromising Data Integrity

Frank J. Farach, PhD[1], Owen McGettrick[1], Charles Tirrell[1], Clark Evans[1], Alejandro Mesa[1], Leon Rozenblit, JD, PhD[1]
[1]Prometheus Research LLC, New Haven, CT

Abstract

Behavioral and biomedical researchers value data integrity, data exploration, and data sharing, but traditional research databases have unacceptable trade-offs among these important data management functions. This case study explores the design, development, and user-acceptability of RexMart, an open-source application designed to maximize data exploration and sharing without compromising data integrity.

Introduction

Clinical research places great demands on data integrity, exploration, and sharing. The stakes are high: Low-integrity data cannot be trusted to yield valid inferences; data that cannot easily be explored are difficult to analyze; and data that are difficult to share hinder collaboration and reanalysis (e.g., meta-analyses). In our prior qualitative research, researchers rated these issues among the most important to address in data management.[1] Unfortunately, many data management solutions optimize for one of these dimensions at the expense of others. Researchers often manage data using spreadsheets or statistical software because their denormalized structure makes certain kinds of data exploration and sharing convenient, but this approach jeopardizes data integrity, data-analytic flexibility[2], and scalability. Conversely, normalizing data optimizes data integrity but constrains the design and performance of query interfaces.[3] This case study explores the design, development, and evaluation of RexMart, an open-source application designed to optimize data integrity, exploration, and sharing.

Methods

We interviewed system designers and examined the informatics literature for design strategies both within and outside research information systems. Several architectures were proposed and compared against internal and user requirements. Once an architecture was selected, we developed the first major release of RexMart and conducted acceptance testing with four users at a major research university. The open-source code can be found at https://bitbucket.org/rexdb/rex.explore_ui-provisional and https://bitbucket.org/rexdb/rex.explore-provisional.

Results

Architectural analysis revealed a promising solution that, to our knowledge, has not been implemented elsewhere for research data. Specifically, a well-normalized relational data warehouse stores research and study management data, providing robust control over data integrity. Users access data via a data mart, a point-in-time snapshot of data from the warehouse that has been reorganized into a dimensional relational data model. The schema of the resulting data mart is configurable by analysts so that each on-demand data mart can be re-normalized or denormalized to fit analytic needs. The first major release of this open-source application allowed users to create data marts; search for variables by column and table metadata; produce summary statistics; filter columns by value; build basic queries through the UI; and run, save, and share queries. In acceptance testing, although users wanted to be able to share databases with other users, they liked the metadata search, summary statistics, and saved query functionality.

Discussion

Data integrity, exploration, and sharing are critical to scientific progress but are difficult to maximize within the same database. By storing research and study management data in a data warehouse and providing a user-friendly way to create data marts from the warehouse for exploration, we were able to deliver a major release of RexMart that provided a satisfactory data exploration environment without compromising data integrity. Future work will focus on implementing database sharing, improving data analysis features, and providing native interoperability with data formats and models that are commonly used in clinical research, such as CDISC ODM, HL7 CDA, and dbGaP.

First Feasibility of a Surveillance Platform Combining Community-Submitted Symptoms and Specimens for Molecular Diagnostic Testing

Jennifer Goff[1,2], Aaron Rowe, PhD[3], Rumi Chunara, PhD[2,4]

[1]Boston University School of Public Health, Boston, MA; [2]Boston Children's Hospital, Boston, MA; [3]Integrated Plasmonics Corporation, San Francisco, CA ;[4]Harvard Medical School, Boston, MA

Introduction

Modern informatics-based participatory surveillance systems are one approach to obtaining disease information in real-time and at scale. Internet-based Influenza surveillance systems have been developed and deployed nationally for years in 10 countries in Europe as well as Australia and here in the United States through Flu Near You[1, 2, 3]. However, none of these Internet-based systems employ molecular techniques to rapidly verify the intelligence data they garner. By combining Internet-based participatory surveillance with advanced molecular methods for high sensitivity and specificity viral identification, the aims of this project are to not only serve to advance epidemiological knowledge of respiratory viral infections (such as symptom profiles, spatio-temporal distribution and risk groups) and validate existing approaches that only incorporate self-reported symptom information, but also to demonstrate a new type of informatics platform that combines crowdsourced diagnostic samples and symptom reports, enabling individuals to understand what infection they may have as well as what is circulating in their community.

Methods

We began by building a kit that includes an off-the-shelf saliva collection kit and nasal swab with viral collection medium. These kits were paired with customized instructions and instructional videos. A cohort of lay volunteers in the Boston area was recruited through a variety of modern channels. Enrollment was driven largely by announcements on local radio stations and word of mouth. Paid online advertisements and social media were also considered as means of recruiting volunteers to the study. These volunteers reported symptomatic information to the Flu Near You website and then performed self-testing and specimen collection upon becoming symptomatic with influenza like illness. Our instructions called for performing the tests within the first 48 hours of cold or flu symptoms. Samples were tested by multiplex PCR.

Results

Adherence to the study protocol by subjects was good with some indicators that there is room for improvement in our instructional materials and kit contents. Between December 1 2013 and March 1 2014, 295 participants enrolled in the study and received a kit. Participants submitted kits an average of 2.30 days (95 CI: 1.65 to 2.96) after symptoms began (Figure 1). Of those reporting symptoms, 55 participants completed the diagnostic samples by March 1 and specimens were sent for nucleic acid analysis. 6 out of 30 specimens tested to-date were positive for Influenza (Influenza A, 2009 H1N1), 13 tested positive for at least 1 coronavirus and 1 for respiratory syncytial virus (RSV). Nasal and saliva samples gave the same result for all samples except one influenza sample (no positive detection in saliva).

Conclusions

These preliminary findings present multiple initial conclusions: diagnostic samples can be generated by the public, and oral specimens are comparable with nasal specimens when used for the identification of upper respiratory pathogens, however further larger studies will increase the power of these conclusions. Volunteer recruitment, and ensuring compliance of volunteers with study protocols, are among the main challenges of this work. Revisions to the written & video instructions distributed with the specimen collection systems should yield higher levels of volunteer adherence to protocols. As well, targeted recruiting through Public Health Associations (e.g. Caucuses in the American Public Health Association) can assist in the scaling and representativeness of the participants. Additionally, all specimens collected during this study have been banked and different laboratory diagnostic platforms and DNA extraction and PCR techniques may be experimented with. Future studies will increase the amount of reported data, which will enable evaluation of the relationship between reported symptom profiles and viral etiology as well as spatio-temporal distribution of upper respiratory infection, and impact of these efforts on individual's public health and healthcare seeking behavior.

Learning Objectives: Participants will learn about strategies for adapting the ALL Initiative for CHCs, how to anticipate barriers and facilitators for successful implementation, and the potential impact of such implementation.

Abstract. *Clinical decision support systems (CDSS) that harness electronic health record (EHR) data have improved diabetes care quality in integrated health care systems such as Kaiser Permanente (KP).[1,2] Little is known about how such tools can be implemented in community health centers (CHCs), though CHCs could gain substantially from adapting effective CDSS tools to their environment. Our study is the first clinical trial to study the implementation in CHCs of an EHR-based CDSS strategy developed in an integrated care setting. The diabetes quality improvement intervention – the 'ALL Initiative' – was highly effective at KP, and uses EHR-based CDSS tools (e.g. alerts, panel management data rosters, order sets). We adapted this intervention for implementation in 11 CHCs and studied its impact on rates of guideline-based cardioprotective medication prescribing among diabetic patients. Our presentation will describe: (1) How the EHR-based CDSS tools were adapted for use in CHCs; (2) How and why the adapted tools were or were not used by CHC staff, and lessons that could inform future efforts to adapt EHR-based CDSS tools for use in CHCs; and (3) Impact of the implemented CDSS tools in the study CHCs.*

Background: KP's diabetes quality improvement intervention, the 'ALL Initiative,' uses diverse EHR-based CDSS tools (automated point-of-care alerts, patient data management tools, streamlined order sets, etc.) to improve rates of guideline-based cardioprotective prescribing. We sought to assess whether and how this intervention, which was very effective in the KP setting,[1,2] could be adapted for implementation in CHCs, whose patient populations, EHR resources, workflows, and needs differ greatly from those in integrated care settings.

Methods: Eleven CHCs in the Portland, OR area participated in our 'translational' randomized trial. We worked with clinic staff and EHR designers from the OCHIN community health information network to adapt KP's intervention for CHCs. Briefly, in place of KP's panel management-based tools and top-down implementation approach, we created a 'menu' of stand-alone CDSS tools and relied heavily on practice facilitators. Next we implemented the adapted CDSS tools in the study clinics through a staggered randomized process, where six 'early' clinics implemented one year before the remaining five 'late' clinics. We used segmented regression analyses to estimate the change in prescribing rates post-implementation; the model also tested for differences in trends over time. We collected quantitative EHR data to assess the impact of the EHR-based CDSS tools on rates of guideline-based prescribing, and qualitative data to identify barriers and facilitators to use of the tools.

Results: We substantially adapted KP's EHR tools for use in the study CHCs, but were able to provide functions similar to those available at KP. Barriers to integrating the tools into the CHCs included: providers' mistrust of automated alerts and habit of ignoring them; challenges inherent to fitting CDSS tools into existing clinic workflows; that the tools address one aspect of diabetes care, rather than all aspects of patient care; developing population-level tools that allow providers leeway to make decisions for individual patients; and other factors related to using EHR tools to support practice change. Despite these barriers, implementing the ALL CDSS tools was associated with significant improvements in rates of guideline-based prescribing: the percent of 'early' CHC patients appropriately prescribed a statin increased from 59% to 68% in 12 months (a 15% relative increase); the percent appropriately prescribed ACE-inhibitors, from 69% to 76% (a 10% relative increase). The 'late' CHCs showed no concurrent change until their implementation began one year later, but one year post-implementation, the late CHCs' guideline-concordant prescribing rates had improved 57% to 68% (statins), and 64% to 74% (ACE-inhibitors).

Discussion: It is feasible to adapt EHR-based CDSS tools developed in the private sector for implementation in CHCs. Our results illustrate the impact of KP's ALL Initiative when implemented in CHCs, and the challenges involved in using EHR-based tools to support practice change and quality improvement efforts in CHCs.

Automating Performance Measures and Clinical Practice Guidelines: Differences and Complementarities

Mary K. Goldstein MD MS,[1, 2] Samson W. Tu MS,[2] Susana Martins MD MSc,[1] Connie Oshiro,[1] Kaeli Yuen,[1] Tammy Hwang,[1] Dan Wang PhD,[1] Amy Furman PharmD,[1] Michael Ashcraft MD,[1] Paul A. Heidenreich MD MS[1,2]

[1]VA Palo Alto Health Care System, Palo Alto, CA; [2]Stanford University, Stanford, CA

Abstract

Through close analysis of two pairs of systems that implement the automated evaluation of performance measures (PMs) and clinical decision support (CDS), we contrast differences in their knowledge encoding and necessary changes to a CDS system that provides management recommendations for patients failing performance measures. We trace the sources of differences to the implementation environments and goals of PMs and CDS.

Introduction

PMs and CDS are methods to improve quality of care. PMs focus on measuring the quality of care that patients have received, while CDS focuses on providing information to assist health professionals with clinical management. We seek to characterize concretely the ways automated support for PMs and guideline-based CDS differ yet can be complementary to each other. We closely examine two pairs of PM and CDS implementations that use clinical data from the Department of Veterans Affairs (VA) VISTA system to generate performance reports or patient-specific CDS recommendations. We analyze how PMs and CDS differ or complement each other in their cohort definitions, knowledge modeling, workflow integration, use of data, and output structure.

Methods

1. We first compared a pair of systems, one designed for PM and the other designed for CDS, as follows: (a) Heart Failure (HF)-PM, an implementation of National Quality Forum (NQF) measure on the use of angiotensin-converting enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB) therapy for left ventricular systolic dysfunction (NQF 0081) [1], and (b) HF-CDS, the ATHENA-CDS system [2] that implements similar recommendations from a national guideline for the management of heart failure [3]. 2. Second, we analyzed the changes required to implement a CDS within the context of a PM system rather than in the context of patient visits. The PM system is a production "clinical dashboard" implementation of PMs that generates reports at the levels of VA service network, medical center, provider and individual patient. We integrated ATHENA-CDS system for diabetes with the dashboard to provide recommendations on the management of patients who have failed the PMs.

Results

1. HF-PM and HF-CDS use 33 and 13 criteria, respectively, to select the cohort of patients who should receive ACEi or ARB (9 identical, 4 similar, and 26 unique to the PMs). PM criteria are more explicit in ruling out patients not active in the health care system (death or not visited in last 12 months; criteria not needed in CDS system because it triggers only when a patient is being seen by a health professional). Sixteen HF-PM exclusions not in HF-CDS are conditions for which HF-CDS provides alerts that allow providers to exercise clinical judgment; HF-PM excludes these patients from the cohort because PMs are designed to specify a cohort with a high likelihood that the numerator criteria apply (reduce false positives). That is, whereas these criteria are the same, they are incorporated in the PM and CDS differently (exclusion criteria versus alerts). The output of HF-PM includes the proportion of patients meeting the measure as a percentage of those eligible for the measure. The output of HF-CDS consists of recommendations for managing patients' problems. 2. Integrating the CDS into the PM dashboard to display when the PM is not met (a) allows the CDS to issue alerts based on data computed by the PM dashboard that are important for care but only indirectly related to PM (e.g., medication possession ratios), (b) requires the CDS to change treatment targets (e.g., hemoglobin A1C for diabetic patients) when the targets differ between PMs and guidelines that the CDS implements (because, as is the case for hemoglobin A1C, guidelines recommend setting individualized targets, whereas PM select a target that will identify high risk patients), (c) requires that the CDS trigger and display of CDS recommendations be coordinated with the existing PM dashboard user interface.

Discussion

We use the implementations of two pairs of PM and CDS to demonstrate concretely how PM and CDS differ (e.g., in cohort definitions) and yet can complement each other (e.g., synergy of data and patient selection). We adapted an experimental CDS system to provide recommendations and displays consistent with a production PM dashboard.

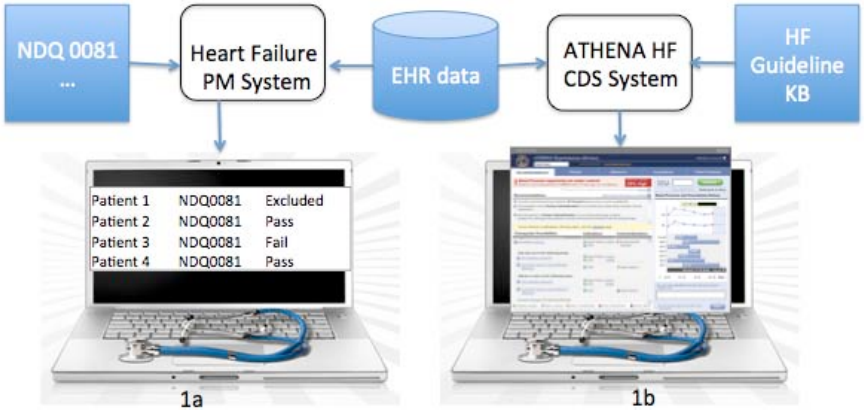

Figure 1. In the first pair of systems, Heart Failure PM (1a) is designed to generate reports on whether a cohort of patients satisfies the NQF 0081 performance measure. ATHENA HF CDS System (1b) is designed to generate detailed management recommendations for guideline-based care at the time of a patient encounter.

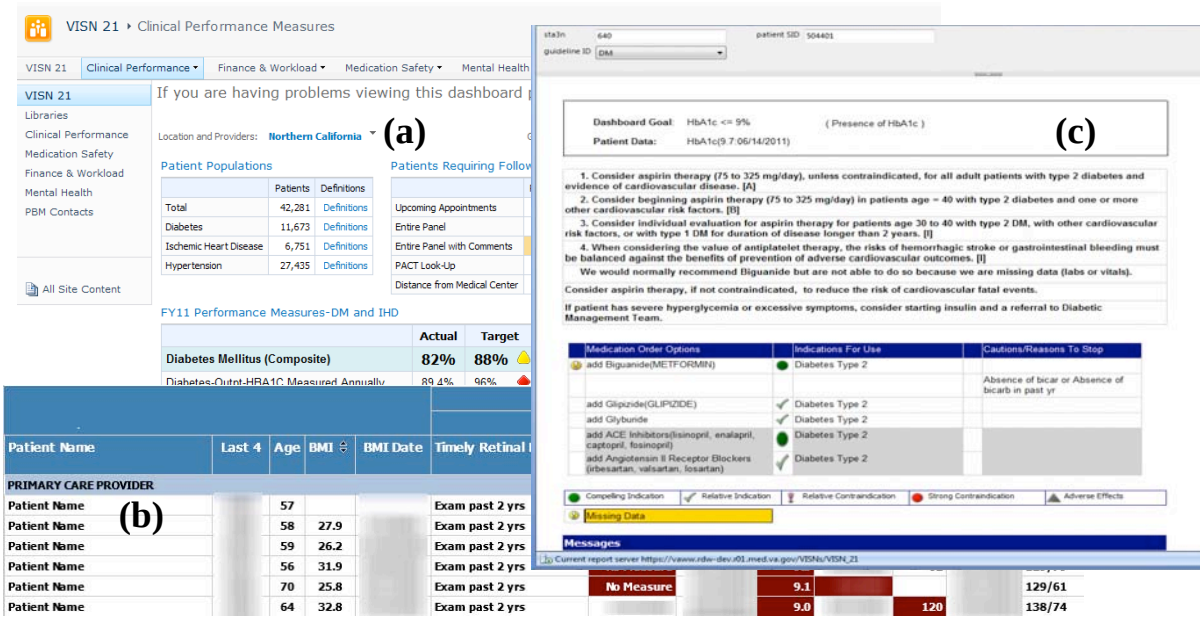

Figure 2. In the second pair of systems, Dashboard PM displays patients' performance with respect to VA PMs as a population-based summary (a) and as individual patient records (b). For selected PMs, a user can bring up ATHENA CDS recommendations on how to manage the treatment of patients who fail to meet the PMs (c).

Federating Air Quality Data with Clinical Data

Ramkiran Gouripeddi, MBBS, MS[1,2], Naresh Sundar Rajan, MS[1,2], Randy Madsen, BS[2], Phillip B. Warner, MS[2], Julio C. Facelli, PhD[1,2]
[1]Department of Biomedical Informatics, [2]Center for Clinical & Translational Science, University of Utah, Salt Lake City, UT

Abstract: *Air Quality (AQ) has been associated with various clinical conditions and requires further clinical research. Linking AQ data with clinical data is often challenging and requires diverse expertise. In this preliminary work we show the feasibility of using OpenFurther in federating these heterogeneous data for performing clinical research.*

Introduction: AQ have been associated with various adverse health effects including asthma, cardiovascular problems, respiratory infections and cancers and impaired glucose tolerance during pregnancies[1–4]. The Salt Lake Valley (SLC), Utah is prone to winter inversions where colder surface temperatures trap fine particulate matter ($PM_{2.5}$) which poses serious health concerns[5]. The summer months in the valley have increased ozone (O^3) levels. Researchers at the University of Utah are embarking on various clinical studies to understand associations between the peculiar AQ patterns in SLC and clinical conditions such cerebral venous thrombosis, exacerbations of idiopathic pulmonary fibrosis, suicide, reproductive outcomes and various cancers.

Methods: To understand the requirements for federating AQ data with clinical data we elicited use-cases from clinical researchers. Primary needs are to understand the risks associated with being exposed with various air pollutants. Manifestations following exposure could occur immediately or after a lag phase and could persist over long durations. Pathophysiology and mechanisms of many of these manifestations are not well understood at this time. The federation needs to support the spatio-temporal variations of air pollutant concentrations and location of an individual and the timing of the occurrence of conditions. Although current research associates single pollutant and clinical conditions, future areas of research could include exposures to multiple pollutants. Requirements for the granularity of AQ data vary from hourly readings to monthly averages depending on the study. Difficulties in understanding and integrating AQ data with clinical data is a limitation in performing research.

OpenFurther[6,7] is an informatics platform that supports federation and integration of data from heterogeneous and disparate data sources. It supports clinical and translational research by bringing data directly to researchers without requiring the technical expertise to query large databases or knowledge about the data source. The main components of OpenFurther include a terminology/ontology server (TS) that stores local and standard terminologies as well as inter-terminology mappings; an in-house developed metadata repository (MDR) that stores metadata artifacts for each data source and the relationships between different data models; a query tool a researcher can leverage to design a clinical research query; a federated query engine that orchestrates queries between the query tool, MDR, TS and the data sources; data source adapters to facilitate interoperability with data sources; and administrative and security components (Figure 1). We evaluated the feasibility of federating limited datasets from the Utah Department of Environmental Quality[8] using OpenFurther.

Conclusion: We were able to select different cohorts of patients living in SLC counties and having clinical conditions (e.g. asthma) occurrences that were related to the temporal variations of air pollutant concentration. Future work will include the ability to select data models that provide best estimates for areas and times when air monitor measurements are unavailable along with uncertainties. We will extend this framework to federate other AQ data sources such as a web-service from the Environmental Protection Agency's Air Quality Datamart[10] making it applicable to all regions of continental United States; balloon[11] and satellite-derived aerosol optical depth measurements[4]; and model a high resolution spatio-temporal AQ grid that cross-links to patient locations and condition occurrences**.**

Patient Web-Portals: Can Internet Access Explain Differences in Use Among Patients with Chronic Conditions?

Ilana Graetz[1], Courtnee Hamity[2,3], Vicki Fung[4], Nancy Gordon[3], Mary Reed[3].

[1]Department of Preventive Medicine, University of Tennessee Health Science Center, Memphis, Tennessee; [2]School of Public Health, University of California at Berkeley, Berkeley, California; [3]Division of Research, Kaiser Permanente Northern California, Oakland, California; [4]Mongan Institute for Health Policy, Massachusetts General Hospital; Harvard Medical School, Boston, Massachusetts.

Introduction: Patient web-portals have the potential to improve access to care and patient engagement. Meaningful use incentive payments will require that physicians provide patients online access to their health records and the ability to exchange secure emails. The digital divide could limit access to web-based portals among disadvantaged groups. We examined the association between patient characteristics and internet access, and how they relate to use of a patient web-portal.

Methods: A stratified random sample of adult members of an integrated delivery system who were in a chronic disease registry (asthma, diabetes, CAD, heart disease, and hypertension) completed surveys by mail, by internet-based survey, or by telephone interview. During the study period, all members could access a web-portal to send a secure email to a healthcare provider via a web browser. Study participants reported how often they used the internet, if they used to their own computer or smartphone to access the internet, and if they used the web-portal to email a provider in the last year. All analyses were weighted for sampling proportions. We used multivariate logistic regression to assess the association between patient characteristics (sociodemographic and health status) and internet access. To examine characteristics associated with sending secure email to healthcare providers, we examined two model specifications: 1) adjusting for patient characteristics only, and 2) adjusting for patient characteristics, plus frequency of internet use and devices used.

Results: Among 1041 respondents (87% response rate), 59% were white, 44% were age 65+, 27% had household income <$40,000, and 29% had a high school education or less. Overall, 71% used the internet regularly (daily, weekly or monthly), 72% used their own computer and/or 21% used a smartphone to access the internet, and 56% used the web-portal to email a provider. In multivariate analyses, respondents with lower income and education were less likely to use their own computer or smartphone for internet access ($p<0.05$). Blacks and Hispanics were less likely than whites to access the internet using their own computers ($p<0.001$) and respondents age 65+ (vs. 18-44 years) were less likely to use smartphones to access the internet ($p<0.01$). After adjusting only for sociodemographic characteristics, those who were male, age 55+ (vs. 18-44 years), Black or Asian (vs. white), with lower income and education were less likely to have emailed a provider ($p<0.05$). After also adjusting for internet use and devices, only differences by education and gender remained ($p<0.01$). Regular internet use and access via a personal computer were associated with emailing a provider ($p<0.01$); smartphone access was not, but the portal mobile application was not available during the study period.

Discussion: Regular internet use and having a personal computer could explain differences in web-portal use to email providers by age, race, and income. Education and gender-related differences in use of email remained even after controlling for internet access. As the availability and use of patient web-portals increase, it is important to understand which patients have limited access and what barriers they face. Improving internet access and making web-portals available across multiple platforms, including mobile, may reduce disparities in portal use.

Refining a Patient Risk Assessment using Adjusted Clinical Groups (ACG) with Outpatient Lab Results

Kimberly Gudzune MD MPH, Klaus Lemke PhD, Hadi Kharrazi MD PhD, Jonathan Weiner DrPH
The Johns Hopkins University; Baltimore, MD; USA

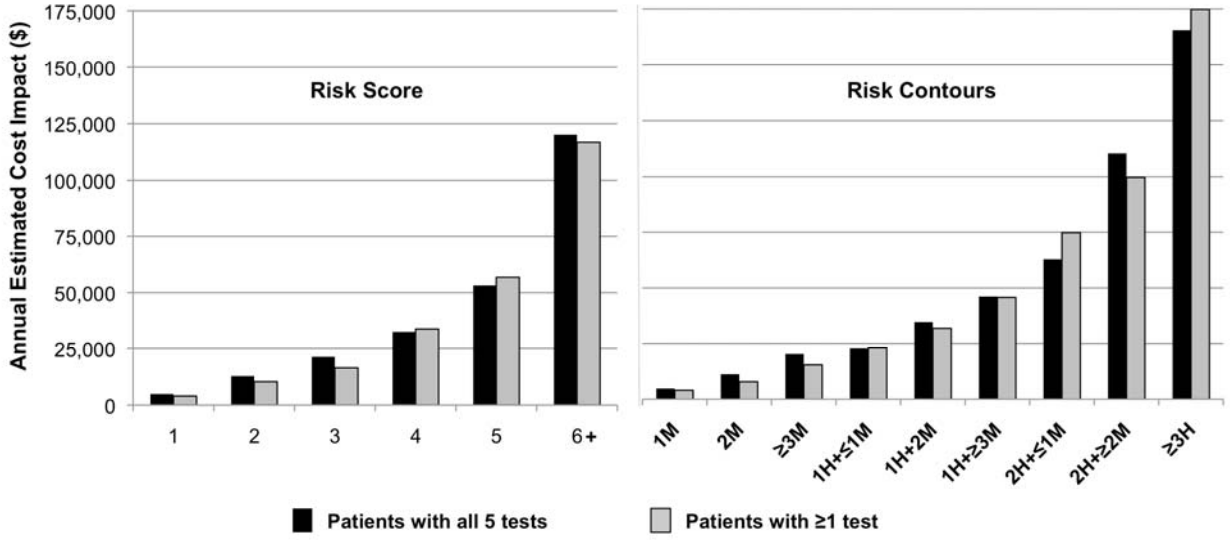
Introduction: Researchers and insurers have relied upon claims-based risk adjustment like the Johns Hopkins Adjusted Clinical Groups (ACG) system; however, electronic medical records (EMR) may provide a new source of data to enhance these claims-based systems. Prior studies have demonstrated that single outpatient laboratory tests can predict prospective costs [1-2], and risk scores based upon admission laboratory tests can predict inpatient mortality [3-6]. However, we know of no studies that have used multiple outpatient laboratory tests to predict healthcare costs. Our objective was to develop an approach to define “lab-based risk” using common outpatient laboratory results, and then test the value of these new measures on refining risk assessment.

Methods: We used 2009-2011 data from IMS Health, which includes enrollment, claims and lab information for three health plans. We examined common outpatient labs including electrolytes, liver function tests, and complete blood counts. Using regression tree analyses, we partitioned each lab test into risk tiers based on concurrent annual costs (low <$20,000, moderate $20,000 to <$60,000 high ≥$60,000). We identified tests with 3 risk tiers (albumin/protein, direct bilirubin, blood urea nitrogen, creatinine, and glucose) to use in the development and testing of two approaches to lab-based risk assessment: “risk score” and “risk contours.” The risk score assigns points to each lab based whether results fall into the high or moderate risk range (2 points and 1 point, respectively). The score ranges from 0-10 points. The risk contours approach designates a level based on counts of both high and moderate risk lab values, resulting in 9 contours that span from “0 high and 1 moderate” to “3+ high” risk results. We analyzed these approaches within two populations: patients who had all five tests (n=7,226) and patients who had at least one of the five tests (n=62,181). We used multivariate linear regression analyses to examine the impact of adding lab-based risk scores or risk contours on concurrent cost prediction beyond the traditional ACG claims-based risk assessment (base model).

Results: Among patients who had all five tests, the estimated cost impact of risk scores ranged from $4,892 (1 point) to $120,146 (6+ points)(Figure). The estimated cost impact of risk contours ranged from $4,786 (1 moderate risk only) to $165,563 (3+ high risks)(Figure). Table displays the differences in R-square for these models as compared to the base model (0.315 and 0.326, respectively, versus 0.224). Among patients who had at least one of the five tests, the estimated cost impact of risk scores ranged from $4,002 (1 point) to $116,803 (6+ points)(Figure). The estimated cost impact of risk contours ranged from $3,983 (1 moderate risk only) to $174,808 (3+ high risks)(Figure). Table displays the differences in R-square for these models as compared to the base model (0.300 and 0.310, respectively, versus 0.232).

Discussion: Both lab-refined risk assessment models explained more cost variation as compared to an ACG only model; however, the risk contours approach performed better than the risk score method. To our knowledge, this is the first study to use multiple outpatient laboratory results to predict healthcare costs. Our results suggest that outpatient laboratory data have utility in improving claims-based risk prediction. Future studies will need to investigate the role of EMR measures beyond lab results, including vital signs and other diagnostic testing, on risk assessment and predictive modeling.

Figure. Adjusted Annual Estimated Cost Impacts of the Base Model + Risk Score Method and the Base Model + Risk Contours Method.



M = moderate risk; H = high risk.

Table. R-square values for regression models using the different lab-refined risk assessment methods

	Patients with all 5 tests (n=7,226)	Patients with ≥1 tests (n=62,181)
Base Model*	0.224	0.232
Base Model + Risk Score	0.315	0.300
Base Model + Risk Contours	0.326	0.310
*Base model includes age, gender, and risk adjustment with ACG resource utilization bands.

Perspectives on Care Coordination and Meaningful Use in the Emergency Department Setting

Saira N. Haque, PhD, MHSA[1], Debbie Travers, PhD, RN[2], S. Trent Rosenbloom, MD[3], Jonathan S. Wald, MD[1,4]

[1]RTI International, Research Triangle Park, NC; [2] University of North Carolina-Chapel Hill, Chapel Hill, NC; [3]Vanderbilt University, Nashville, TN; [4]Harvard Medical School, Boston, MA

Abstract

Although the emergency department (ED) has not been a focus for Meaningful Use (MU) efforts in Stage 1, the care coordination objectives for Stage 2 and proposed updates in Stage 3 have implications in the ED setting. More information about how these MU objectives affect the ED setting is needed. To learn more about MU in the ED, we conducted semi-structured interviews with a variety of stakeholders in the EDs of two academic medical centers. These interviews were designed to elicit information about the utility and feasibility of the objectives in the ED setting, electronic health record (EHR) changes needed to facilitate meeting the objectives, and ways to change them. The interviews were coded using NVivo. Perspectives were consistent within and across both EDs. Suggestions included a modified medication reconciliation process and the importance of automated notifications and care summary transmissions.

Introduction

The emergency department (ED) is designed for rapid, acute care with quality metrics that focus on minimizing patient waits and throughput time. To facilitate coordinated care, the ED must exchange relevant information with community caregivers who are caring for a given patient[1]. Such efforts as the patient-centered medical home reinforce this view. The proposed Stage 3 care coordination Meaningful Use (MU) objectives include these measures to facilitate care coordination: medication reconciliation, provision of targeted care summaries for transitions and after-visit consults and referrals, and notification of significant events. Because MU efforts have not traditionally focused on the ED, stakeholders must learn more about considerations with these objectives unique to the ED.

Methods

We conducted semi-structured in-person interviews of key stakeholders at two EDs at academic medical centers in North Carolina and Tennessee. Participants included physicians, nurses, case managers, pharmacists, and ED administrators. The results of the interviews were transcribed and coded using NVivo to identify themes. A sample of 10% of the interviews was double-coded to ensure consistency.

Results

Staff across both EDs felt that the objectives were useful and would benefit patient care. However, they expressed concerns about how the objectives would be put into practice in the ED. They regarded medication reconciliation as important, but stated that a full reconciliation was incompatible with ED workflow. Participants felt a focused review of pertinent medications was sufficient, with a full reconciliation being deferred to the patient's primary care doctor, inpatient admitting service, or pharmacist. For care summaries and notifications for post-ED visits referrals, participants discussed the importance of short, targeted summaries that could be sent automatically. The need for user-friendly EHRs that fit ED workflows and processes was a consistent theme across objectives. Another theme was the utility of health information exchanges to support care coordination, especially for patients with primary providers outside the local healthcare system.

Conclusion

Participants commented that MU was directed to primary care providers, and they felt the care coordination objectives reflected that direction. They suggested scalable requirements so that they could meet the fast-paced care requirements in the ED while also meeting the spirit of the regulation. The findings point to the need to consider a variety of settings and associated information needs and workflows in the MU objectives.

Enhancing the TURF Framework with a Workflow Ontology

Craig Harrington, MS, MSSW[1], Cui Tao, PhD[1], Keith Butler, PhD[2], Jiajie Zhang, PhD[1]
[1]University of Texas at Houston Health Science Center, Houston, TX;
[2]University of Washington, Human Centered Design & Engineering, Seattle, WA

Abstract

The TURF Framework enables usability analysts evaluate EHRs by analyzing work tasks, users, representations, and functionality. Currently the TURF framework does not have a focus on evaluating clinical workflows across multiple tasks or across individuals [1]. Because clinical workflows are vital to the successful implementation of an EHR, this study will augment the capabilities of the TURF usability framework by incorporating a workflow ontology. A novel feature of the workflow ontology is its use of Butler's Cognitive Work Product (CWP), which complements the TURF framework through its ability to classify workflow actions and resources as contributing to the end goal of the workflow or as overhead. The combination of the TURF framework and the workflow ontology provides a more comprehensive method of evaluating the usability of EHRs.

Introduction

The surge in adoption of electronic health records (EHRs) is not without challenges. As highlighted in a recent NIST report and other sources, a key usability issue is the negative impact that EHRs are having on clinical workflows [2, 3]. This study defines a clinical workflow as "a modular sequence of tasks, with a distinct beginning and end, performed for the specific purpose of delivering clinical care" [4]. To address the challenges of clinical workflows in EHRs, our study shows the value of an ontology as an addition to Zhang's TURF framework for evaluating the usability of EHRs.

Ontologies represent domain knowledge declaratively using formal rules and constraints. After defining the abstract nature of a domain, instances of the domain can be created and validated according to the rules and constraints. We have developed a clinical workflow ontology (CWO) for EHR workflow. The declarative reasoning of the CWO complements the nature of clinical workflows to deviate from templated processes. The CWO further enhances TURF through the application of Butler's Cognitive Work Product (CWP), which views workflows involving cognitive processes as changing the CWP from an initial state to a goal state [5]. Necessary activities are identified as advancing the CWP towards the end goal; other activities are likely to qualify as overhead. By combining the CWO with the TURF framework analysts can evaluate EHRs with a proven framework that supports clinical workflows. With this capability, analysts can identify gaps and design solutions that maximize the usability of their EHRs.

Methods

The TURF framework describes methods to analyze the usability of an EHR based on the work tasks, user requirements, information representations, and system functionality. The CWO will enable the usability analyst to also define the steps of a workflow from the initial state to the completion of the workflow using Protégé (6), an open-source visual ontology editor. As the analyst constructs the steps of the workflow, the CWO will apply logic rules to recognize inconsistencies, missing information, or errors while classifying the activities and resources for each step as necessary or overhead. Additionally the CWO supports entry and exit conditions for each step, enabling the workflow to transition to subsequent states based on event triggers or satisfying conditions as opposed to workflows that are represented as ordered sequences of activities. These features enable the CWO to accurately model clinical workflows, where a medical crisis can short-circuit a swim lane diagram.

Results

Two pilot projects previously modeled with UML class and state diagrams serve as reference models to evaluate the resulting CWO models. By enhancing the TURF framework with the CWO, analysts will be able to leverage the logical reasoning capability of the CWO to accurately represent clinical workflows, classify activities as necessary or overhead, and identifying inconsistencies or errors in the modeled clinical workflow.

Discussion

The clinical workflow ontology has the ability to represent workflows in a declarative fashion instead of a procedural fashion. This represents a novel way to represent workflows which mirrors the way clinical workflows occur. Future considerations for the ontology are to incorporate the ability to generate timings for different paths that a workflow can take and the ability to suggest representation methods for the data.

Automatically Enhancing Discharge Instructions with Pictographs to Improve Patient Recall and Satisfaction

Brent Hill, RN MS PhD Candidate, Seneca Perri, PhD, Jinqiu Kuang, MS, Rebecca Morris, MSPH, Katherine Doyon, BSN, MS, Bruce E Bray, MD, Qing Zeng-Treitler, PhD
University of Utah, 421 Wakara Way, Ste 140, Salt Lake City, Utah 84108

Introduction

Hospital inpatient discharge is important for patients as they are responsible to complete hospital discharge instructions to enhance recovery and prevent adverse events.[1] Several factors limit patient understanding of discharge instructions including the typically large amount of discharge information, the influence of acute and/or chronic disease, medication side effects and poor sleep quality while hospitalized which negatively impacts cognition and memory.[1] One method to improve discharge instructions is to include illustrations, which can increase focus, comprehension, recall and adherence.[2-4]

Our team developed a system called Glyph that contains a pictograph library and each pictograph's associated terminology for medical concepts in a database.[5] The Glyph system preprocesses free text, annotates a set of concept extraction modules that locate and annotate text strings, composes images from grammar patterns, and then renders images, generated by the rule engine, for the corresponding text.[5] (Examples Table 1)

Methods

The aims of the study, to examine immediate and delayed recall and patient satisfaction with discharge instructions, were tested using a between group experimental design with pre-discharge and post-discharge measures of free recall and patient satisfaction. Patients were randomized to either receive pictograph enhanced discharge instructions or standard discharge instructions and then given a copy of their discharge instructions to review for up to 15 minutes immediately prior to inpatient discharge. Recall was assessed by asking patients what they remembered about each section of their discharge instructions. Content the patient verbalized was highlighted on a non-illustrated copy by a study nurse. Words remembered were counted, and a normalization ratio was calculated based on the actual number of words in the patient's discharge instructions. Satisfaction was assessed using a Likert-type scale ranging from 1 as completely dissatisfied to 7 as completely satisfied. Patients were called one-week post discharge and asked the same questions about their discharge instructions. One hundred and forty-four patients completed the study. Additionally, patient demographics (Table 2) were also collected.

Results

An independent-samples T-Test was conducted to determine if there were differences in group means at discharge (immediate recall) and one-week post discharge (delayed recall). The results indicate a significant recall effect for immediate recall, $t(142) = -3.1$, $p < .01$ and a non-significant recall effect at delayed recall, $t(142) = -0.26$, $p = .80$. At discharge, patients who received pictograph enhanced discharge instructions remembered more of their discharge instructions (5.8% vs. 4.3%) than patients who received standard discharge instructions when only illustrated sections of discharge instructions were compared against the same sections in standard discharge instructions.

A Mann Whitney U was conducted to evaluate patient satisfaction with discharge instructions. Two satisfaction questions were asked at discharge and one-week post discharge. There were no significant differences between the groups at discharge for either question, $z = -.53$, $p = .6$ and $z = -.99$, $p = .32$ respectively. For one week post-discharge, significant effects were found in the pictograph enhanced discharge instruction group for question 1 (understandability), $z = -2.4$, $p = .016$ but not for question 2 (inclusiveness).

Discussion

The results of this study validate Glyph-generated instructions effect on improvement in patient recall and satisfaction with discharge instructions. Specifically, pictograph enhancement improved the pre-discharge recall of instructions by 29% and post-discharge satisfaction by 5%. It demonstrates that automated illustration of patient instructions is not only feasible but also beneficial. This informatics intervention can be easily disseminated as Glyph is an automated system.

Learning Objective

After participating in this session, the learner should be better able to apply informatics applications to improve patient education.

A Web-Based Resource for Medication Management of the Community-Dwelling Older Adult

Kay Jansen, DNP, PMHCNS-BC, RN [1], Amy Coenen, PhD, RN, FAAN[1], Jeeyae Choi, PhD, RN[1]
[1]University of Wisconsin-Milwaukee, College of Nursing, Milwaukee, WI, USA

Abstract

The purpose of this project was to create an evidence-based electronic resource that facilitates nurses to identify actual or potential medication management problems and to target individualized interventions to improve outcomes for older adults living in the community. A discussion of the development process and a demonstration of the web-based resource will be provided with a plan for further research to test the tool in practice.

Introduction

The need for a resource or decision support system (DSS) to assist nurses in managing medications for older adults living the community is supported by a number of factors. Some of the factors for increased risk of medication problems include (a) clinical complexity of the population, (b) desire to remain independent as long as possible, (c) multiple risk factors for problems with medication management, and (d) high costs of hospitalizations and emergency department visits[1]. The US Agency for Healthcare Research and Quality published guidelines for nurses to provide quality medication management for community-dwelling older adults. An electronic resource could help nurses translate evidence into practice and assist with documentation and evaluation of care. The intention of this study was to develop a web-based prototype for an evidence-based DSS using standardized nursing terminology.

Methods

The data sources for this study included (a) a national clinical practice guideline for medication management of the community-dwelling older adult and (b) the expert opinion of four gerontology nurses from Norway and the United States (including the guideline author) with clinical and informatics expertise. The researchers organized content using the nursing process model components of assessment, diagnosis, intervention, and evaluation. Concepts were coded using the International Classification for Nursing Practice (ICNP) to direct development of algorithms to automatically generated tailored care plans for patients based on individual assessments. Use of ICNP can also facilitate translations of the resource and data reuse for quality evaluation and program planning.

Results

An evidence-based resource to support nurses and caregivers with medication management of the community-dwelling older adult was developed for further testing. The resource is a prototype web-based clinical DSS that includes templates for documentation of individual assessments to identify risk factors. Based on the individual risk factors, a tailored care plan is generated for each patient to direct and document interventions provided for medication management. Data documented by nurses are coded in ICNP to facilitate reuse for evaluation.

Discussion and Conclusion

The medication management resource provides one example of an evidenced-based DSS for nurses. Further testing is proposed for nurses' use of the DSS in the homecare setting with older adults and persons with chronic illness. Expanding testing to include informal caregivers and family members, as well as patients, is also planned. This tool could be the first of several web-based resources nurses could access using ICNP. The integration with other electronic health record data to support evidence-based clinical decision making would be essential to optimal use, for example accessing pharmacy and laboratory data for medication reconciliation and monitoring drug dosing.

Acknowledgement

The authors would like to thank the International Council of Nurses in supporting this study.

Evaluation studies of the Librarian Infobutton Tailoring Environment (LITE): An open access online knowledge capture, management, and configuration tool for OpenInfobutton

Xia Jing, M.B., Ph.D.[1], James J. Cimino, M.D.[2], Guilherme Del Fiol, M.D., Ph.D.[3]

[1]Department of Social & Public Health, Ohio University College of Health Sciences & Professions, Athens OH;

Abstract

Introduction*: The Librarian Infobutton Tailoring Environment (LITE) is a Web-based knowledge capture, management and configuration tool, with which users can build profiles used by OpenInfobutton, an open source infobutton manager, to provide electronic health record users with context relevant links to online knowledge resources. We conducted evaluation studies of LITE in order to explore users' attitudes and acceptance and to guide future development.* ***Methods****: The evaluation consisted of an initial online survey to all LITE users, followed by an observational study of a subset of users in which evaluators' sessions were recorded while they conducted assigned tasks. The observational study was followed by administration of a modified system usability scale (SUS) questionnaire.* ***Results****: Fourteen users responded to the survey and indicated good acceptance of LITE with feedback that was mostly positive. Six users participated in the observational study, demonstrating average task completion time of less than 6 minutes and an average SUS score of 72.* ***Discussion****: LITE can be used to fulfill its designated tasks quickly and successfully. Evaluators proposed suggestions for improvements in LITE functionality and user interface.*

An Infobutton is a clinical decision support tool embedded within the electronic health records (EHRs) that has been proven to be an effective tool to meet clinicians' information needs at the point of care[1,2]. Certification of "Meaningful Use" of EHRs by the Office of the National Coordinator for Health Information Technology now requires the inclusion of Infobuttons that use the *HL-7 Context-Aware Knowledge Retrieval ("Infobutton") Standard*[3]. The Librarian Infobutton Tailoring Environment (LITE)[*] is a tool that can be used to define context-specific links (CSLs) that can be served up by OpenInfobutton (an open source and centralized Infobutton manager) when an EHR user clicks on an Infobutton in a particular clinical context (task, patient demographics, user demographics, concept of interest, etc.). In order to investigate users' acceptance of LITE and to improve the usability of LITE, we conducted a multi-part evaluation.

LITE allows users to define health care knowledge resources (such as MedlinePlus or UpToDate) and then define institution-specific CSLs that describe the EHR contexts. The definition of institutions, resources and CSLs is guided by "wizards" that step the user through each process. LITE is managed by Drupal. PHP and MySQL are used in back end to support necessary programming functions.

We conducted a three-stage evaluation of LITE[4] from November 2013 to January 2014: a general survey of all users, an observational study of a subset of users, and a follow-up survey of the subset (Fig 1). The surveys were generated and managed by Survey Monkey. The observational study was conducted via Webex. Evaluators conducted the designated tasks and shared their desktops via Webex. All the screen activities were captured via BB FlashBack. Audio recording was optional during the observational study. The researcher observed the entire process and was available for assistance. The researcher also asked follow up questions if an evaluator expressed confusion or particular interest at any point. A modified system usability scale (SUS) questionnaire was administered to observational study participants. We used a published method for calculation of SUS scores[5]. All LITE users were invited for all stages of the evaluation.

The response rate for the general evaluation survey was 16.5% (14/85). The general impressions were quite positive (Fig 2). The users' assessments were that LITE fulfills its main tasks successfully and quickly. The average time for observed users to complete each task was less than 6 minutes under a very relaxed test atmosphere (Table 1). Questions and interviews were common during the tests. The average SUS score for LITE is 72 (the average SUS score from literature is 68). Users felt that of the current Infobutton standard parameters age, sex, EHR task, subject, subtopic, encounter type (.e.g., inpatient, outpatient), user type (e.g., provider, patient), and language were useful but that performer discipline was not necessary. Evaluators suggested that "race or ethnicity" and "geographic locations" be added as new parameters. The main suggestions can be classified into the following categories: navigation, content layout and organization, functionalities, annotations and instructions, interface presentation features and suggestions external to LITE. The main expectations from the evaluators about LITE were: users expected LITE to be more intelligent with more interactions with users; they expected more control over interface display; they desired greater clarity and consistency in the use of terminology within LITE interfaces; and they expected trouble shooting tips, educational materials and support. Due to the small sample size, the findings of the observational and usability sessions need to be considered with caution.

Using Phenotype Portal for Checking Clinical Guideline Recommendation Compliance

Lara Johnstun, BS[1], Danielle Groat, BS[1], Amol Bhalla, MD, MHSA[1], Kevin J. Peterson, BA[2], Jyotishman Pathak, PhD[2], Adela Grando, PhD[1]

[1]Arizona State University, Biomedical Informatics, Scottsdale, AZ
[2]Mayo Clinic, Health Sciences Research, Rochester, MN

Abstract

Phenotype Portal is a tool that currently uses de-identifed Mayo Clinic and InterMountain Healthcare clincal data to identify cohorts for electronic clinical quality measures (eCQMs) using Meaningful Use (MU) terminologies and standards. Our goal is to test Phenotype Portal's reusability by using the Multiparameter Intelligent Monitoring in Intensive Care (MIMIC II) clincal data, and to understand Phenotype Portal's scalability to the problem of clinical guideline recommendation compliance for the treatment of asthma exacerbation.

Introduction

The Phenotype Portal[1] is a platform for clinicians and investigators to identify patient cohorts using electronic health record data by leveraging informatics-based phenotyping processes. The use of Phenotype Portal requires the clinical data to be standardized and normalized to MU conformant terminology and value set[2] standards using Clinical Element Models (CEM). Samples of both structured and unstructured data from Mayo Clinic and InterMountain Healthcare EHRs have been used in the Phenotype Portal to demonstrate semi-automatic execution of eCQMs, which are electronic specifications of clinical quality measures required for EHR reporting for MU. Currently, the Phenotype Portal supports 50 eCQMs for identifying cohorts for clinical quality measures. Our aim is to use intensive care unit data from MIMIC II[3] clinical database to obtain preliminary data to understand if the Phenotype Portal could also be used to specify and check adherence to evidence-based clinical recommendations. MIMIC II contains de-identified critical care data from hospital information systems, detailing thousands of admissions. MIMIC II clinical database has been previously normalized to ICD-9CM, ICD-9PCS and LOINC, but lacks standard terminologies for other concept categories such as medications and patient encounter types. Pulmonary disease is among the most frequent diagnostic groups present in MIMMIC II, representing 8.84% of assigned ICD-9CM codes. With the focus on pulmonary disease, we chose to check the compliance of medical treatment recommendations from the 2007 National Heart Lung and Blood Institute "Guidelines for the Diagnosis and Management of Asthma." For instance, if a patient is admitted to a hospital for severe asthma exacerbation and is unresponsive to initial treatment with systemic corticosteroids, then adjunct treatment with heliox or IV magnesium should be considered.

Method

First, to standardize and normalize MIMIC II data in accordance to the Phenotype Portal data constraints we proposed automatic methods to normalize medications to RxNorm. SNOMEDCT and CPT codes are added to patient data to explicitly express the implicit concept of ICU care. Patient demographic values are normalized to codes consistent with value set standards. Second, to specify the chosen asthma guideline recommendations into the Phenotype Portal we created electronic specifications for asthma clinical recommendations within the eCQM framework (see Figure 1) using the Measure Authoring Tool[4] (MAT) and authored value sets (see Table 1).

Results

We imported asthma clinical guideline specifications into the Phenotype Portal to check the conformance of the asthma recommendations in the MIMIC II data and found that Phenotype Portal was able to identify cohorts of patients whose treatment conformed to asthma clinical guidelines from a sample of MIMIC II ICU patients.

Conclusions

Our research shows that Phenotype Portal can be reused with normalized clinical data different from the Mayo and InterMountain Healthcare data originally used. In particular, mapping MIMIC II data into PhenotypePortal required extra methods for normalizing medications, patient encounters and demographics.

In terms of adaptability, this preliminary work on specifying and checking compliance with clinical recommendations has helped to gain insights on the scalability of the Phenotype Portal to address a problem different from its original purpose of identifying patient cohorts for MU. Identification of cohorts for conformance with clinical recommendations allows developers of clinical decision support (CDS) to evaluate a baseline for how well clinical guidelines are being applied before the development and implementation of CDS tools. If baseline conformance cohorts reveal a need for CDS development, the effectiveness of the CDS tool can be measured following its implementation.

Generating Problem Lists Using Medication Reconciliation

Joshua W. Joseph, MD[1], David T. Chiu, MD[1], Larry A. Nathanson, MD[1], Steven Horng, MD MMSc[1]
[1]Beth Israel Deaconess Medical Center / Harvard Medical School, Boston, MA

Abstract

Introduction*: Problem lists succinctly summarize a patient's history, and help to quickly identify important medical conditions. As patients' medical conditions and records become more complex, obtaining a useful problem list can be inefficient and inaccurate, particularly for critically-ill patients. Regulatory agencies will soon require providers to maintain an up-to-date problem list at every patient encounter. It has been suggested that medication reconciliation could be used to help clinicians meet this regulatory mandate. We hypothesized that we could generate an accurate, automated problem list from the ED medication reconciliation.*

Methods*: The objective of this study was to evaluate the sensitivity and specificity of an automatically generated problem list from the medication reconciliation. The study was approved by our institutional review board. We performed a 1 month retrospective chart review of patients admitted via the ED of an academic, tertiary care center with an annual volume of 55,000 patients. Consecutive adult patients were enrolled between 03/29/2013 - 04/30/2013. Patients who were admitted and had an inpatient discharge summary within a year were included. Patients who eloped or signed out against medical advice were excluded. Our rules-based method used the First Data Bank medication ontology to group medications into therapeutic classes. We then applied a set of clinically derived rules to those therapeutic classes to predict asthma, hypertension, diabetes, congestive heart failure (CHF), and history of venous thromboembolism (VTE). This prediction was compared to the problem list found in the EM attending note, the electronic medical record, and the last discharge summary (gold standard). We additionally trained and validated probabilistic predictive models. A logistic regression and neural network with 5 nodes in 1 hidden layer were created for both CHF and stroke risks. Sensitivity and specificity were determined by maximizing Youden's J statistic. These parameters were compared with a problem list derived from the EM attending note, the problem list in the electronic medical record (EMR) and the rule-based method.*

Results*: A total of 603 patients were enrolled from 03/29/2013 - 04/30/2013. The rules-based method had a sensitivity of 0.71 for asthma, 0.85 for hypertension, 0.75 for diabetes, 0.53 for VTE, and 0.59 for CHF. Comparatively, the attending note had a sensitivity of 0.53 for asthma, 0.59 for hypertension, 0.71 for diabetes, 0.58 for VTE, and 0.36 for CHF, while the electronic record's problem list had a sensitivity of 0.38 for asthma, 0.40 for hypertension, 0.67 for diabetes, 0.31 for VTE, and 0.42 for CHF. The logistic regression model had a higher sensitivity than all other methods for detecting CHF. Logistic regression also had a higher specificity for stroke compared to the rules-based method, and equivalent to the rules-based method for CHF; however, it had a lower specificity than either the EMR problem list or the EM attending for both stroke and CHF. The AUC for logistic regression for CHF and stroke are 0.84 and 0.85, respectively. The AUC for neural network for CHF and stroke are 0.96 and 0.98, respectively. The Hosmer-Lemeshow test was not significant p >0.05 for the logistic regression model indicating that the model was well calibrated.*

Discussion*: The rules-based method was sensitive for conditions that are normally treated with an exclusive class of medications. Probabilistic methods such as logistic regression and neural networks are more sensitive at detecting more complex diseases such as CHF and stroke history than rules-based method, problems already documented in the electronic medical record, or EM attending note. Neural networks have an even higher sensitivity at detecting history of stroke than This suggests that algorithms have the potential to facilitate more efficient and thorough problem list documentation, but further investigation is required.*

Table: Sensitivity and Specificity of an Automated Problem List and Standard Lists

	Medication Algorithm		EMR[1] Problem List		EM Attending Note

Evaluation of Stage 3 Care Coordination 'Meaningful Use' (MU) Objectives among Eligible Hospitals (EH)

Hadi Kharrazi, MD PhD[1]
[1]Johns Hopkins School of Public Health, MD

Introduction

Industry experts and government officials have expressed skepticism over the effectiveness of Meaningful Use (MU) in improving health outcomes and lowering cost, and expect upcoming MU stage implementation to be complex and costly. Thus, policy makers have decided to evaluate the feasibility and usability of MU measures before finalizing stage 3 MU objectives (MU3) in 2014, and perhaps adapt recommended changes before an MU3 rollout in 2016/2017.

This federally-funded project aims at evaluating the feasibility and practicality of two specific MU3 measures that are proposed by ONC (Office of National Coordinator) to incentivize eligible hospitals (EH) to effectively adopt and use EHRs (Electronic Health Records) for inpatient/outpatient care coordination. The focal objectives of these care coordination MU3 measures are: (1) sending hospital-generated referral results to the original requestors in outpatient settings; and (2) timely notification of key patient care team members of significant life events that occurred during a hospitalization.

Methods

The study includes three phases: In the first phase, the research team analyzed the current measures and developed a matrix of pragmatic data, workflow and organizational elements that represent the two MU3 care coordination measures. This matrix is used to develop a data collection instrument to evaluate the two MU3 measures (#305 & #308). In the second phase, 10 eligible hospitals (5 in Maryland and 5 in Arkansas), representing a variety of hospital types and sizes, participated in the data collection and pilot roll-out of these two measures. In the last phase, the research team summarized the results into challenges and opportunities in adopting these two MU3 measures and reflected on the aggregated feedback collected from EHs to policy makers.

Results / Principal Findings

Results of the first and second phase of the study show mixed outcomes. None of the participating hospitals had the capability to roll-out the two MU3 care coordination measures on a system-wide scale; however, a number of them are able to collect the necessary data to evaluate the feasibility of the roll-outs. Based on the preliminary findings, the majority of the participating hospitals did not collect the necessary data required to report these two MU3 measures in an electronic format. The only participating critical access hospital dropped out of the study due to resource constraints. Common EHRs do not have the capability to automate the roll-out of these measures; however, there are innovative approaches to enhance the current EHRs and/or adjust the clinical or administrative workflows to adapt these measures in near future. Detailed results of the study, including differences found in the feasibility of these two MU3 measures based on hospital specifications, will be reported to the Agency for Healthcare Research and Quality (AHRQ) in Sep 2014.

Discussion

The overall concerns of participating hospitals with these two MU3 measures are summarized in the following categories: (1) Ambiguous Definition: Most EHs found the definition of these two measures unclear and with no specified boundaries or denominators; (2) Overlapping Measures: Some EHs found these two MU3 measures somehow overlapping with existing MU2 measures (#303) and suggested merging them; (3) Beyond EHRs: A number of hospitals considered some of the elements of these objectives to go beyond the EHR's common functionalities and suggested that other IT tools may be required to achieve these MU3 objectives; (4) Connectivity to Health Information Exchanges (HIEs): HIE connectivity can play a significant role in some of these MU3 care coordination measures and hospitals that do not have access to such connections may not be able to fully achieve these measures; and, (5) Hospital Specs / IT Infrastructure: A number of hospitals specs and underlying IT infrastructure play a role in achieving advanced care coordination measures. For example the rural and semi-rural hospitals that participated in the study could not collect the necessary raw data to measure these objectives while larger academic medical hospitals could achieve parts of the measures.

The final project report will provide policy recommendations to policymakers on how to refine these measures in order to increase their impact; propose EHR innovations that would better enable providers to meet the proposed objectives; and, suggest ways to increase the value of these two care coordination measures to providers. In conclusion, new care coordination measures of MU3 will be challenging for EHs unless EHR vendors automate some aspects of data collection and exchange, and also the clinical staff/providers adjust their workflow to enhance care coordination.

Extracting Drug-drug Interactions from Literature Using a Rich Feature-based Linear Kernel Approach

Sun Kim, PhD[1], Haibin Liu, PhD[1], Lana E. Yeganova, PhD[1], W. John Wilbur, MD, PhD[1]

[1]National Center for Biotechnology Information, NLM, NIH, Bethesda MD

Abstract

Introduction: When two or more drugs are being co-administered, there is a chance they will interact. This is especially true for new drugs which often have side effects that may remain unnoticed until they are available to the public. Identifying such interactions is of significant importance in the early detection of unintended or harmful drug reactions, leading to reduced number of drug-safety incidents and reduced healthcare costs. While a number of resources containing drug-drug interaction (DDI) information have been created (1, 2), the wealth of up-to-date DDI information is hidden in unstructured medical texts which are growing exponentially. This calls for developing text mining techniques to automatically identify DDIs from free text.

Methods: In this work we develop an efficient and scalable state-of-the-art system for identifying drug-drug interactions and classifying them into four predefined relation types: mechanism, effect, advice and general interaction, as described in (3). Among existing DDI extraction methods, the best performing ones are based on Support Vector Machines (SVM) with non-linear, composite kernels. However, these approaches incur more computational cost because the complexity of the underlying kernels accumulates and additional learning is required to optimize the weights for individual kernels. We propose a DDI extraction method using a linear SVM classifier with a rich-feature representation. The 'one-against-one' strategy (4) is used to further classify DDIs into four types.

Five different types of lexical and semantic features are defined to capture the characteristics of data. Lexical features include individual word features with position information and word pair features for non-adjacent words in a sentence. Integrating position information into word features is important because one sentence often involves multiple drug mentions and the position information helps differentiate the context of interacting pairs from that of non-interacting ones. Word pair features capture expression patterns involving distant words in a sentence and can effectively complement word features. Semantic features include dependency relations, parse tree structures and noun phrase-constrained coordination features. Dependency relations describe governor-dependent relations between words and are able to capture long-range dependencies between target drug mentions. Parse tree structures encode a sequence of grammatical tags representing a syntactic traverse from one drug to another. Finally, the noun phrase-constrained coordination features examine whether target entities appear in a coordination of three or more entities, an unlikely scenario for discussing interactions. The word pair and the coordination features are novel to our approach. Figure 1 illustrates the preprocessing step and features extracted for an example drug pair.

Results: We evaluated our system on the DDIExtraction 2013 challenge corpus (5) and compared it with the top scoring systems in the challenge. Our approach achieves an F1 score of 0.676 on the challenge test data, as compared to 0.651 and 0.609 reported by the two best performing teams FBK-irst (6) and WBI(7), both based on non-linear kernels. The highest F1 score reported in the challenge by linear kernel systems (8) is 0.594. Table 1 reports our DDI detection and classification performance as compared to the top three ranking teams.

Discussion: As evidenced by the results on the publicly available dataset, our method is the first linear kernel-based approach that achieves the state-of-the-art performance on both DDI detection and classification tasks. A rich feature representation appears to be beneficial as it allows a linear SVM system to achieve a competitive performance. We consider our method a strong alternative to the nonlinear, composite kernel-based approaches. The advantage of linear kernel approaches is in their simplicity and scalability. As demonstrated in (9), often linear kernels are the only practical choice for training large-scale datasets. Moreover, straightforward representations used by linear kernels enable an intuitive interpretation of results. In addition, the 'one-against-one' strategy proves vital for classifying extracted interactions into specific types. Unlike other top scoring systems, our method does not incorporate external domain-specific information, which suggests it may be more generalizable across different domains. The inherent simplicity and transparency of the proposed method could be especially beneficial if it is used as a part of a more complicated schema.

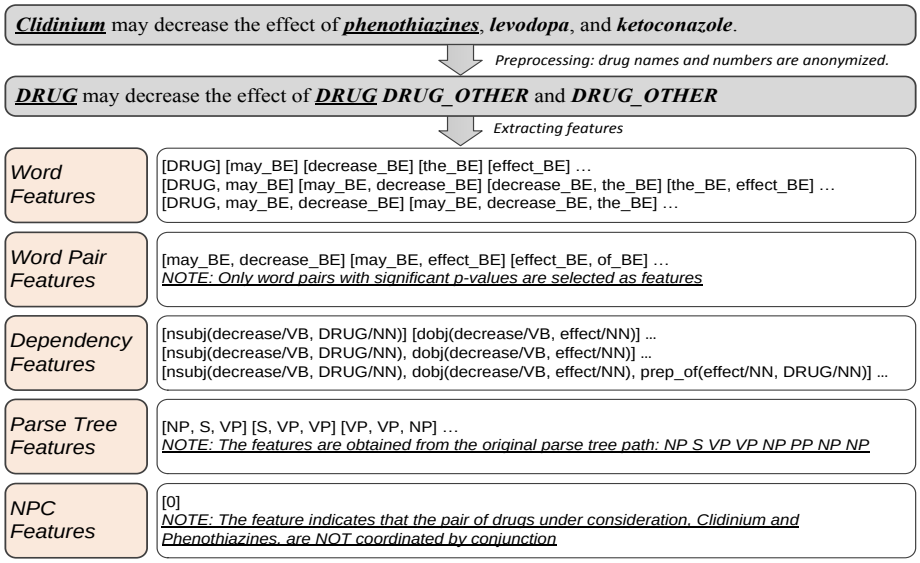

Figure 1. An example of preprocessing and feature extraction. The underlined pair of drugs, *clidinium* and *phenothiazines*, is a candidate interacting pair. 'BE' in word features denotes position (between candidate drugs).

Table 1. Performance comparison between the proposed method and top ranking approaches on the test data of the DDIExtraction 2013 challenge, evaluated by the official metrics. The performance is reported in F1 scores.

Method	Detection & Classification	Detection	Mechanism	Effect	Advice	General Interaction
Our Method	0.670	0.775	0.693	0.662	0.725	0.483

Evaluation of an Early Prototype of a Patient-Centered Decision Aid to Improve Accuracy of Breast Cancer Risk Perception

Rita Kukafka, DrPH, MA[1] Katherine D. Crew, MD, MS[1], Haeseung Yi, MPA[1], Tong Xiao[1] , Parijatham S. Sivasubramanian, MD[1], Alejandra N. Aguirre[1],
[1]Columbia University, New York, NY

Abstract

This study evaluated a breast cancer prevention decision aid (DA), RealRisks, which incorporates experience-based dynamic interfaces to communicate risk aimed at reducing inaccurate risk perceptions, particularly in low-numerate women. We employed a mixed methods approach to assess accuracy of risk perceptions and the acceptability of the DA using qualitative focus groups and a quantitative survey. After interacting with RealRisks, the difference in perceived vs. actual breast cancer risk significantly improved for 5-year risk (p=0.008), but not lifetime risk (p=0.20). In addition, while participants were uncertain of their risks before RealRisks, none of them expressed uncertainty after RealRisks. Not only did participants think that RealRisks was easy to use and useful, but they also became less worried about breast cancer and increased their knowledge of breast cancer.

Introduction

Breast cancer risk assessment and prevention strategies, such as chemoprevention are underutilized in the U.S.[1] Reasons for low uptake include inability to routinely screen for high-risk women in the primary care setting, inadequate time for counseling, and insufficient knowledge about risk-reducing strategies. To address patient-related barriers, we developed a prototype of a web-based decision aid, RealRisks, that incorporates heuristic or experience-based techniques for learning and problem-solving to change perceptions and behaviors.[2]

Methods

The RealRisks DA includes modules on breast cancer risk, genetic testing, and chemoprevention. Patient-provider dialogue is modeled using narrative, and participants learn about their risk by interacting with 2 games of experience-based risk interfaces, which demonstrate average 5-year and lifetime breast cancer risk. Women recruited from Northern Manhattan (N=34) participated in this study. We employed a mixed methods approach to assess improved accuracy of risk perceptions and acceptability using qualitative focus groups and a quantitative survey. Paired t-test and McNemar's test were used to compare within-individual changes in accuracy of perceived breast cancer risk. For the qualitative approach, a content analysis was conducted.

Results

Participants were mean age (53.4), Hispanic (61.8%) and low numerate (41.2%). According to the Gail breast cancer risk assessment tool (BCRAT), the mean 5-year and lifetime breast cancer risk were 1.11% (±0.77) and 7.46% (±2.87), respectively. After interacting with RealRisks, the difference in perceived and actual breast cancer according to BCRAT improved for 5-year risk (p=0.008), but not for lifetime risk (p=0.20). Accuracy of perceived breast cancer risk (defined as within ±5% of actual lifetime risk according to BCRAT) improved from 52% to 70% (p=0.10). Even in the subgroup of women with low numeracy, accurate risk perceptions improved from 45% to 70%. In particular, 4 out of 5 women who overestimated their lifetime breast cancer risk by >30% had accurate risk perceptions after exposure to RealRisks. Eighty-five percent of the participants responded that RealRisks was easy to use (90.91%), helped them understand breast cancer risk factors (87.88%), and was useful (87.88%). In addition, almost 80% became less worried about breast cancer after interacting with RealRisks (78.79%). More than 90% responded that RealRisks increased their knowledge of breast cancer (93.94%).

Conclusion

This study demonstrated a significant improvement in accuracy of perceived breast cancer risk after exposure to RealRisks in a multi-ethnic low-numerate population. Based upon feedback from our focus groups, we were able to identify information needed to fully represent the important issues of breast cancer risk to further develop our prototype for testing in a randomized controlled trial.

Introduction

Low-quality of health services and sub-optimal performance of healthcare providers in low-income countries is a critical global problem.[1,2] Audit and feedback (AF), defined as the provision of performance summaries to healthcare providers, is a commonly used intervention that can significantly improve clinical performance.[3] The use of electronic information technology in the delivery of healthcare (eHealth), which is growing rapidly in low and middle-income countries,[4,5] is creating unprecedented opportunities to provide individualized performance feedback to healthcare providers. Knowledge about barriers to the use of eHealth data for quality improvement is increasing,[6,7] but our understanding of how and when eHealth data can be successfully used to generate performance feedback is limited. An electronic medical record (EMR) system, deployed nationally in antiretroviral therapy (ART) clinics in Malawi, collects data that national ART supervision teams use to provide quarterly, clinic-level performance feedback.[8,9] The aim of this study was to identify and describe barriers to using EMR data for individual-level AF for healthcare providers in Malawi, and to consider how to design technology to overcome these barriers.

Methods

We used conceptual models for the cognitive processing of feedback[10] and implementation of evidence in clinical settings[11] to inform qualitative data collection. We distributed flyers in eight public hospitals in Malawi where the EMR is used, to recruit nurse and clinical officer participants for semi-structured interviews, observations of EMR use, and informant feedback. We interviewed a convenience sample of 32 participants (18 nurses, 14 clinical officers) in six district hospitals and two central hospitals. We audio recorded interviews and transcribed them verbatim. We collected field notes during observations and informant feedback meetings. To protect participants' rights we conducted interviews in private rooms, kept research data confidential, and did not document identifiable information. We analyzed the qualitative data using Crabtree and Miller's editing method,[12] using team input in the development of an iteratively derived codebook. We used an adjudication process to resolve differences between coders and interpreted the thematic findings using the lens of our conceptual models.

Results

We identified four barriers that can prevent eHealth data from being usable for AF in low-resource settings: provider rotations, disruptions to care processes, performance indicator stability, and user acceptance of eHealth. *Provider rotations* refers clinic staff schedules that prevent healthcare providers from working in a clinic long enough to receive quarterly performance feedback. *Disruptions to care processes* are unexpected events such as infrastructure failures, drug stockouts, and eHealth outages that are beyond the control of the individual and that limit improvement potential, reducing the relevance of performance feedback. *Performance indicator stability* refers to the average length of time that a performance indicator, once created, remains useful for measuring individual clinical performance. For example, performance indicators may become obsolete due to changes in EMR software or to the guideline recommendations on which they are based. *User acceptance*, concerning an individual's use of and attitudes toward the EMR, constrains the ability to conduct AF for individuals who do not use some EMR functions.

Discussion

To successfully use EMR data in Malawi, clinical AF interventions must adapt to provider rotations, disruptions to care processes, performance indicator stability, and user acceptance of eHealth. AF interventions may be improved by monitoring data quality errors associated with these barriers, and by failing gracefully when the quality of data becomes too low. To improve the effectiveness of feedback generated using eHealth data, a reporting tool could further facilitate adaptation by enabling a supervisor to select or tailor performance feedback messages, based on the supervisor's knowledge about the recipient and the clinical situation during the reporting period.

A Curvilinear Path Towards Interoperability: A Curvilinear Path Towards Interoperability: Homogeneity and Disparity in Models of Health Information Exchange

James R. Langabeer II, PhD[1], Tiffany Champagne, PhD[2]

[1]University of Texas Health Science Center, Houston, TX; [2]Greater Houston Healthconnect, Houston, TX

Introduction

The benefits of sharing patient health information between providers have been well documented[1]. Improved care coordination, reduced duplication of tests and scans, and improved efficiencies are just a few of these benefits. Yet barriers and inconsistencies continue to plague the path towards interoperability. Institutional organization theory contends that organizations with similar intent and vision are similarly shaped by external forces and consequently tend to develop homogeneous strategies and become isomorphic[2]. In the case of health information exchange (HIE), billions of dollars were infused into community HIEs for a common purpose and intent, yet there has not been significant research into the extent to which they share similar strategies or approaches. In this research, we argue that the evolutionary path towards national interoperability has resulted in an adaptive change by local organizations to a barrage of barriers, which has created in effect a curvilinear trajectory. More clear, decisive action at the policy level could alter the course significantly. Using case study data from 25 regional health exchanges, we explore the disparity in organizational models in health exchanges nationwide.

Methods

This study employed qualitative methods, combining detailed informant interviews and case study data from 25 large, geographically distributed HIEs throughout the nation. The research question we sought to address centered on the degree of homogeneity in the approaches and organizational "models" being deployed by health exchanges throughout the country. Since institutional theory of organizations suggests that external forces and similarities of purpose drive organizations towards isomorphism (similarities in form and function), we would hypothesize a high level of similarity in the overall model. Yet, anecdotal evidence suggests that HIEs are evolving heterogeneously. To test our question, we created a framework of 8 factors that comprise key aspects of organizational strategy or models of HIEs. We collected and assessed data from a random sample of 25 large (10% of total population) exchanges for analyses focusing on these variables: 1) Organizational Size; 2) Reach/Scope; 3) Market Strategy; 4) Technical Architecture; 5) Maturity and Phase; 6) Vendor Platform; 7) Sustainability Model; 8) Service Offerings.

Results

We found evidence of widespread similarity in most market-based strategies and services, with some notable disparities. In terms of services offered, nearly all HIEs are approaching this homogenously, yet there was disparity in technical models and architectures. The strategy appears similar, the tactics slightly different. HIEs in this sample were relatively mature in age (mean of 6.6 years) but low in maturity (>50% not live in operational phase). Nearly all organizations (92%) have adopted a participation or transaction fee structure generated from a wide variety of stakeholders (providers, payers, systems) yet most have very little earned revenue to date outside of grant revenue. Most HIEs (72%) have adopted a hybrid or centralized data model approach, but are growing slower than anticipated due to data privacy concerns from stakeholders. A patient opt-in model of consent is the least risky, but more organizations (64%) have adopted an opt-out approach. Service offerings were largely limited to direct and continuity of care document (CCD) exchange.

Results

The seamless flow of interoperable data represents an achievable vision, but there should be greater sharing of best practices and more rigor in developing unique strategies that work in each local market. This homogeneity in models and strategy shows little local adaptation, but it also poses a significant threat to the overall path towards interoperability. Organizational theory suggest that the "planned change" of what was intended as outcomes for HIE investments has been morphed by the "adaptive change" to the reality of sustainability and local market barriers. Lacking stronger direction from policy-makers at the time of the large "stimulus" investments, very little

prescriptive assistance, compressed timelines, and lack of known best practices, HIEs have evolved in much the same way. This will create multiple failures, but also examples of likely success. Researchers should follow these strategies and performance to better understand which models are optimal, to ensure the long-term viability and success of interoperability in healthcare.

Combining Heterogeneous Databases to Detect Adverse Drug Reaction

Ying Li[1], Santiago Vilar[1], Ying Wei[2], Carol Friedman[1]

1. Department of Biomedical Informatics, 2. Department of Biostatistics, Columbia University, New York, NY, 10032

Introduction

Early detection of adverse drug reactions (ADRs) is critical for advancing patient safety. The rapid growth of large electronic health records (EHRs) provides an opportunity to use the information in the EHRs to hasten ADR discovery. Currently, most studies of ADR detection have either been limited to use of a single data resource to discover an ADR and then have independently used another resource for validation, or required that the ADR occurs in the two resources leading to low sensitivity.[1,2] We hypothesize that integration of evidence from multiple resources should lead to a more effective ADR detection system, and propose a methodological framework that computationally combines the adverse event reporting system of the Food and Drug Administration (FAERS)[3] with information in EHRs as well as external knowledge for ADR detection.

Methods

Our study is based on 2.7 million FAERS reports and 0.3 million EHR patients from 2004 to 2010. The framework includes three steps in Figure 1: 1) Obtaining statistics in each resource for drugs associated with an ADR of interest while adjusting for confounding effects; 2) Determining the p-values based on the empirical null distribution derived from a set of reference negative drugs and combining two p-values with weights inversely proportional to the variance associated with the statistic for that resource, i.e., more weight is assigned when variance is small; 3) Re-ranking initial signals based on similarity of their adverse drug event (ADE) profile[4] based on the Side Effect Resource (SIDER) database.[5]

The framework was applied to four serious ADRs, acute renal failure (ARF), acute liver injury (ALI), acute myocardial infarction (AMI), and gastrointestinal bleeding (GIB), and was evaluated according to a published reference standard (RS) containing known positive and negative ADRs based on available knowledge.[6] The combined statistics in step 2 is compared with statistics from each resource and from a random system based on the RS using area under the receiver operating characteristic (ROC) curve (AUC) and its relevant significance test. We also report precision and recall at the well-known cutoff value, which is 0.05 for one-sided pvalues of EHRs and FAERS and for the combined pvalue of the combined system, as well as AUC for each ADR. The re-ranking results from step 3 are then evaluated using top K precision.

Results

We restricted our positive and negative control test cases to those that had at least one person exposed and diagnosed with an ADR of interest in the EHR and at least one case report in FAERS, resulting in 104 positive and 176 negative controls. The results show that the combined system achieved an AUC of 0.73, which is not significantly different from 0.77 based only on FAERS, but is significantly better than 0.51 based only on EHRs and better than 0.53 based on a random system. The performance for the 4 ADRs are shown in Table 1. The recall of the combined system was better than or the same as the two individual resources for all 4 ADRs. Among them, ARF achieved the best recall while ALI had the worst. However, the AUC and precision of the combined system was between the individual systems.

On average, FAERS contributed 69% and the EHRs contributed 31% to the combined p-value based on variance. Table 2 shows true signals (TP) that were only detected by the combined system. Nevertheless, the combined system did not identify two TP, trandolapril and interferon beta-1a associated with ALI, which were detected by FAERS alone. There were no TPs detected using the EHR alone. We only re-ranked initial signals for which we had ADE profile information, amounting to 45 positive and 21 negative controls. Table 3 shows that re-ranking always achieved better precision in top positions of signals compared with the combined system.

Discussion and Conclusion

The main limiting factor of our study was the small EHR population we had access to, limiting EHR signal detection capability, and impairing performance of the combined system. In future work, we plan to include additional EHR data from multiple sites.

To our knowledge, the framework presented here is the first that aims to computationally combine diverse information from three different resources for ADR detection. Our preliminary results demonstrate that combining FAERS with EHR data using a computational approach was effective in achieving improved sensitivity, which is crucial for early detection. Furthermore, enhanced precision was obtained by re-ranking the signals using additional external knowledge.

Figures and Tables

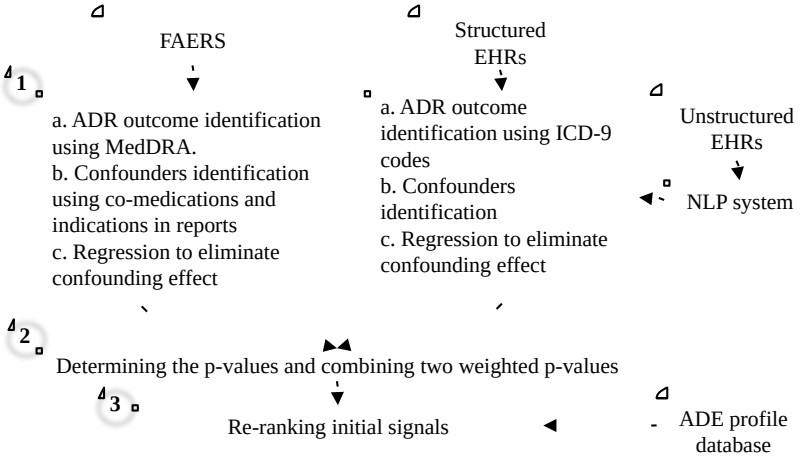

Figure 1 Methodological framework for generating, combining and re-ranking signals

Structured EHR data in this context refers to International Statistical Classification of Diseases (ICD-9) which are linked to each unique patient.

Unstructured EHR data in this context refers to EHR narratives, which are processed using the natural language processing (NLP) system.

ADR outcome is defined by Health Outcomes of Interest library provided by Observational Medical Outcomes Partnership (OMOP).

Detecting Epilepsy Diagnosis in Clinical Notes: A Comparison of Traditional Text Classification Methods

Todd Lingren, MS, Pawel Matykiewicz, M.Phil., Yizhao Ni, PhD, Shannon M Standridge, MD, Katherine D Holland, MD, Imre Solti, MD, PHD, MA, Tracy A Glauser, MD, John P Pestian, MBA, PhD

Cincinnati Children's Hospital Medical Center (CCHMC), Cincinnati, OH

Introduction and Background

Natural language processing (NLP) is essential to exploit the information in Electronic Health Records (EHRs) that may identify many diseases, including epilepsy. Several information extraction systems, such as the clinical Text and Knowledge Extraction System (cTAKES)[1] have been developed to make the Unified Medical Language System (UMLS) more accessible for biomedical NLP research. In this study we evaluated the effectiveness of using UMLS for the identification of 37 different epilepsy-related diagnosis and treatment markers from neurology clinic notes. We then compared this method with traditional text-extraction methods that used manually annotated clinical data.

Data and Methods

Two hundred and sixty-seven neurology clinic notes from 51 patients were selected from a previous study (575.67 tokens per note on average)[2]. Two different feature types were selected for comparison. The first feature set was created via traditional method of text classification, using unigrams, bigrams, and trigrams. We applied the National Library of Medicine stopword list[3]. All words were lower-cased, all numerals were substituted with the string NUMB for abstraction, and all non-ASCII characters were removed. The notes included 7718 unique ngrams. The second feature set was based on UMLS Concept Unique Identifiers (CUIs). CUIs were obtained using cTAKES (ver. 3.0) to process the clinical notes. cTAKES employs machine learning and regular expression UMLS dictionary lookup to obtain CUIs from clinical narratives. The feature set included 624 unique CUIs. Negated and non-negated CUIs were counted as distinct features.

The 37 different epilepsy-specific treatment and diagnosis markers (e.g., partial epilepsy, generalized epilepsy, specified seizure past frequencies, unsatisfactory control reasons, and various drug treatment types) comprise the gold standard labels and were added by three annotators. Each note can belong to multiple classes. Average inter-annotator agreement was 0.816 (Krippendorf's alpha). Classification was performed using cosine kernel SVM one-vs-rest in 15-fold cross-validation and multidimensional grid search parameterization. We scanned three feature selection methods using rigorous internal and external cross-validation techniques[4]: information gain (IG), IG ratio, and Pearson correlation coefficient; four feature weighting functions: identity function, IG, IG ratio, and Pearson correlation coefficient; cost (C) was screened at $2^{0.5}$ increments from 1-32; percent of retained features was also done using 21 point scale. For each label the grid had total 5292 cells[5]. The average number of features used in each classification was different between feature sets. CUI features used an average of 258 features (min 26/ max 515), 2644 ngrams (280/6235), and 2167 ngrams+CUIs (376/5778).

Results and Discussion

Performance was calculated using F1 measure (macro average over all classes). CUIs performed worse (0.672, sd 0.222) (Figure 1A) and ngrams features were best (0.815, sd 0.170) (Figure 1B). Using CUIs and ngrams together performed slightly worse than just ngrams (0.813, sd 0.180, Figure 1C). Paired T-test demonstrated that classification with CUIs is statistically significantly worse than ngrams (p-value 4.734e-08) and worse than ngrams+CUIs (p-value 7.323e-08). The difference between performance of ngrams and ngrams+CUIs was not statistically significant (p-value 0.6821). Features that rank in the top ten significant features more than ten models are shown in Table 1. Six of the top ten features in ngrams+CUIs set are similar to top-10 CUI or identical to top-10 ngram features. Top ten features were calculated using absolute values of support weight vector.

Traditional approach to text classification performed well when applied to detection of diagnostic and treatment-specific markers in clinical notes. Like previously suggested[6], using UMLS CUIs did not improve the classification result in a narrow domain. CUIs seem to represent clinical concepts well (Table 1), demonstrating promise for using CUIs a higher level meaning abstraction. Including CUIs did reduce the average number of features used in classification, which can mitigate possible overtraining. Future work is necessary to augment UMLS CUIs with additional domain-specific knowledge and consider other feature types such as medication codes (e.g. RxNORM)

for targeted classification of specific drug-related markers. Additional future work will focus on replicating the results on a larger data set.

ED Noise & Cognition Interruptions: Do We Have a Jackhammer in the Cockpit?

Mary L. Little, RN, MSN[1], Osman R. Sayan, MD[2], Edward H. Suh, MD[2], Vimla L. Patel, PhD[1,3]

[1]Dept. of Biomedical Informatics, Columbia University; [2] New York-Presbyterian Hospital; [3]New York Academy of Medicine, New York, NY

Introduction

Hospital noise level research has shown sound pressure levels (SPLs) have risen 0.38 dBs each year since 1960.[1] However, few studies address this trend and its effect on patients, staff, communication, and quality of care. The impact of excessive noise on cognitive functioning influences the use of technology. This trend of increasing SPLs affecting communication and cognition, calls for human factors engineering and environmental innovations to reduce noise, maximize user oriented information retrieval, within the electronic health record (EHR), and improve staff and patient experiences.

Methods

An integrated literature review from February–March 2014, produced over 2300 SPL citations which reduced to 13 articles when combined with ED or ICU keywords. Ancestor searches produced 18 additional articles. This pilot investigation of SPLs in the ED is a part of a larger baseline workflow information study of 8 interviews, and over 34 ethnographic shift-change observations with ED attending and resident level physicians. An iPad mini was transformed into a sound meter via SPL meter apps made by SPLnFF and AudioTools; observed decibel readings (dBs), in an A-weighted frequency were causation coded. Sound booth testing to compare app accuracy and effect of an external iMM-6 iDevice Calibrated Measurement Microphone was performed. The iPad mini was held away from the observer's body by 12-18 inches to minimize interference in SPL readings. An extension of this pilot study is underway with greater measurement precision using a digital sound level meter.

Results

Several articles note an average of 73-77 dBs in ED and operating rooms, with occasional spikes of 90 dBs or more. SPLs greater than 60 dBs are associated with an increase in stay length for cataract patients,[2] decrease in mental efficiency, increase in communication based errors, and staff turnover. In the interviews, EHR tasks and inefficiencies were cited as major concerns. ED noise levels were only mentioned once, indicating the possibility of user belief in adjustment or acceptance of the ED noise levels despite literature citing the activation of the sympathetic-adrenal-cortical axis and production of stress hormones.[3] Sound booth testing showed the iMM-6 microphone falsely raised the SPL recordings by 7-8.3 dBs. Without the iMM6 microphone, average ED noise levels were 73.4 dBs. SPL recordings varied among the 3 ED areas based on patient capacity and proximity to the main corridor walking path. The loudest SPL readings occurred with overhead announcements, averaging 87-91 dBs, with a SPL_{max} reading of 108.1.

Discussion

Our initial data show that SPLs >95-100 elicited verbal complaints during the rounding process. These SPLs correspond to subway noise and occasionally a construction jackhammer at 3 feet away. Noise of this magnitude, at a critical time in team transition, affects information integrity, cognition and decision-making. There are several limitations in this pilot study which need to be addressed in future studies. While the Apple platform is extremely stable the apps may vary. Although both apps are highly rated,[4] only the AudioTools app has a recording feature. Additionally, more SPL measurements in various types of EDs and studies of the precise effects on provider cognitive functions are needed for a more comprehensive evaluation of ED noise and effect on technology use.

Sound Associations	dB Level	Hospital Noise Found at this Level
Washing Machine	40	None
Vacuum Cleaner at 1 meter	70	Staff conversations (avg), patient alarms
Garbage Disposal	80	Raised voices
Police Whistles, Subway	90	Paging announcements (avg)
Jackhammer at 1 meter	100+	Paging announcements (max)

Table 1 Comparison of Sounds. EPA hospital max is 45 dbs.

Conclusion

Aviation's sterile cockpit rule prohibits non-essential distractions during critical flight times. However, medicine has not emphasized solutions for the distracting and potentially harmful effect of excessive SPLs on cognitive functions of patients, staff, and workflow communications. This preliminary study using sound meter apps as an effective exploratory tool, highlights the need for more research in this area including interactions with EHRs for provider information retrieval, effective alerts, and safe care team transitions. Use of noise reduction solutions such as sound absorbing panels and volume limiters on audio announcements and other communication devices could be implemented. We need to keep the jackhammers out of our cockpits during the takeoff and landing period of patient handoffs in care team transition.

A Hybrid Electronic Surveillance Design Pattern for Public and Population Health

Authors John W. Loonsk, MD FACMI, Hadi Kharrazi MD PhD, Jonathan Weiner DrPH, The Center for Population Health IT, Johns Hopkins Bloomberg School of Public Health

Introduction

The integration of information technology into public health surveillance has proceeded, as in many other industries, as a combination of both the digitalization of existing paper work processes and the development of new work processes where information technology has presented opportunities for rapid advancement. Current electronic surveillance methodologies represent only an initial step in the digitalization of these public health systems and redundant and competing surveillance investments are plentiful. This analysis of existing electronic surveillance approaches has identified the elements of a new hybrid design pattern to improve integration, minimize provider infrastructure needs, and improve overall public health reporting.

Methods

An analysis of public and population health surveillance needs and existing health information technology surveillance applications and implementations was performed. Syndromic surveillance, biosurveillance, registry, case reporting, and reportable condition reporting systems were all analyzed for common information technology needs and elements. Current and developing data and technology standards were also studied and common attributes were documented.

Results

The analysis of existing surveillance approaches and applications identified numerous common elements and complementary needs. Several issues were identified that contributed to the current lack of integration and this picture for electronic public health surveillance systems. And surveillance in the U.S. can still be incomplete and untimely. There are variations in reporting regulations in different States, categorical disease programs with differing data expectations and standards, and changing case definitions in public health emergency settings. More recently, there are also health department IT resource challenges in the face of the rapid advancement of Electronic Health Records (EHRs) in clinical care and newly developing clinical care population health management activities from the Affordable Care Act (ACA) and other new payment methods.

Discussion

This analysis has identified a new hybrid surveillance digital design pattern that can address current electronic surveillance issues. The design pattern melds elements from syndromic surveillance and traditional case reporting. It uses trigger tables for the automated initiation of sensitive, but non-specific data reporting, and centralized decision logic for the identification of more specific, jurisdictional and condition-oriented reports. Because the decision logic is provided centrally, it can be more readily maintained and updated in a rapidly changing emergency situation. Since the initial reporting is automatically generated, there is the opportunity to address the historic yield issue from clinical care

case reporting. Automation of follow-up to that early indication can minimize or eliminate additional work expectations for health department staff.

Crowdsourcing ICD-11 Sanctioning Rules

Vincent Lou[1], Samson W. Tu MS[1], Csongor Nyulas MS[1], Tania Tudorache PhD[1], Robert J. G. Chalmers MB FRCP[2], Mark A. Musen MD PhD[1]

[1]Stanford University, Stanford, CA, USA, [2]The University of Manchester, Manchester, UK

Abstract

It is difficult and time-consuming for medical professionals to develop and maintain large biomedical ontologies. In this work, we developed a crowdsourcing method for obtaining sanctioning rules for the post-coordination of concepts in the draft ICD-11. Our method utilizes the hierarchical structures in the domain to improve the accuracy of the sanctioning rules and lower the cost of the crowdsourcing process. We used a Bayesian network to model workers' skills, the accuracy of their responses, and our confidence in the acquired sanctioning rules. Furthermore, we developed a method to maximize the quality of the sanctioning rules within a fixed budget for paying workers.

Introduction

The draft ICD-11[1] includes the capability for coders to specify the details of a disease using a combination of ICD codes and qualifiers such as a disease's severity or anatomic location. To ensure the integrity of coded data, such post-coordination requires *sanctioning rules* that specify legal combinations of codes and qualifiers[2]. For a large classification like ICD-11 that has tens of thousands of codes and thousands of terms in the value sets of qualifiers, manual curation of sanctioning rules by subject matter experts (SMEs) poses a formidable challenge. We developed a crowdsourcing method to generate a high-quality draft of the sanctioning rules that SMEs can verify and edit.

Methods

Crowdsourcing involves three steps: 1) defining the microtasks, 2) dividing the overall task into microtasks and publishing the microtasks on a crowdsourcing platform, and 3) collecting and combining answers[3]. Given a disease, we define a microtask as asking anonymous workers on the Amazon Mechanical Turk platform[4], in exchange for a small payment, to answer multiple-choice questions about possible anatomic locations of the disease. For the overall task of obtaining sanction rules for all diseases, we utilize the hierarchy structure of both diseases and anatomic locations to minimize the number of necessary questions. For example, if the disease cannot occur at a location, we don't need to explore the location's children. When we are acquiring the sanctioning rules for a child disease of a previously constrained parent, we start searching from the permitted anatomic locations of the parent instead of top-level locations while giving the workers the option to indicate that other anatomical locations are possible. We use Bayesian networks to model the confidence level on a sanctioning rule, given available workers responses. Initially we asked for responses from 10 workers for each question. With the Bayesian network, we stop asking for more workers once a confidence cutoff is reached. Modeling each worker's accuracy rate further reduces the number of responses needed for a given cutoff. Finally, to maximize the accuracy of sanctioning rules within a given budget, we developed methods to trade accuracy against cost by using reinforcement learning to develop an agent who constantly adjusts the confidence cutoffs during the crowdsourcing process.. Before obtaining sanctioning rules for a new disease, the agent updates the cost distributions for each probabilistic cutoff, compare the result with remaining budget, and choose the 'best' cutoff to maximize a reward function that rewards the number of "finished" diseases and penalizes the number of "unfinished" diseases that can't be tested because of budget limitation.

Results

We performed two feasibility studies using 11 sub-branches of skin diseases in the draft ICD-11. First we used hierarchical pruning techniques to generate microtasks and the 'majority vote' method to aggregating responses. Second we re-analyzed the data obtained in the first experiment using the Bayesian and budget-constraint methods to aggregate answers and to set the stopping confidence levels. Compared to a gold-standard set of sanctioning rules provided by an expert dermatologist, the sanctioning rules crowdsourced in the first experiment have sensitivity and specificity of 0.81 and 0.97 respectively. For the second experiment, on questions where cutoffs can be adjusted, a 69% cost saving was achieved with an accuracy loss of 6%.

Discussion

Our experiments show that crowdsourcing, incorporating Bayesian networks and machine-learning techniques, is a promising method to efficiently acquire sanctioning rules for ICD. Our method can be applied to acquire the constraints between any two class hierarchies.

Quantifying Information Redundancy in Common Laboratory Tests

Yuan Luo, MS[1], Jason Baron, MD[2], Peter Szolovits, PhD[1], Anand Dighe, MD[2]
[1]Massachusetts Institute of Technology, Cambridge, MA, USA
[2]Massachusetts General Hospital, Boston, MA, USA

Introduction: Traditionally, redundant testing can be defined as tests that clinicians cancel after becoming aware of prior results [1]. However, other factors such as bundled tests from automated instruments increasingly contribute to redundant common laboratory tests, which are thought to lead to expanding health care costs or clutter the diagnostic picture at the presence of multiple inaccurate or even inconsistent results. We hypothesize that there may be a broader source to redundant testing – information redundancy. We characterize information-redundant tests as providing diagnostic or clinical information that largely overlaps with other concurrent tests on the same patient. Understanding the potential redundancies in various laboratory tests may be useful in enhancing test selection and result interpretation. In this study, we investigated the degree of information redundancy for erythrocyte sedimentation rate (ESR), given the results of other tests commonly ordered alongside ESR. The ESR is a non-specific marker of acute phase reactant and can be increased in a variety of inflammatory as well as some non-inflammatory conditions. In this report, we predict ESR from other laboratory results, using predictability as an indicator of information redundancy.

Methods: This study used data from inpatient, outpatient and emergency department testing at the Massachusetts General Hospital for specimens collected over a 3 month period with approval from the Institutional Review Board. The final dataset included ESR results and any results from 38 other selected tests that were performed on the same accession (collection) as each ESR test. The 38 others tests, as listed in Table 1, were primarily selected to comprise the tests most commonly performed alongside ESR and included C-reactive protein, CBC parameters and routine chemistry testing. We also included patient age and gender in our dataset and excluded ESR results that were associated with no other laboratory tests.

The final dataset consisted of data from a total of 6486 test collections, which is randomly split into a training set of 4541 collections and a test set of 1945 collections according to a 7:3 ratio. Besides ESR, each collection had a median of 28 of the 38 other tests measured (20-37, IQR). We applied a two-step process to predict ESR. The first step used multiple imputation (MI) to infer results on any of the 38 other tests that were not performed on any particular collection. The second step used regression to predict ESR from age, gender and imputation-completed results of the 38 other tests. We experimented with different MI methods including unconditional mean imputation (Mean), Multivariate Imputation by Chained Equations (MICE) [2], and a random forest based MI algorithm, MissForest [3]. After imputation, we also experimented with different regression methods to predict ESR, including linear regression (LR), Bayesian linear regression (BR), random forest regression (RFR) and Lasso.

Results: Table 2 shows the performance of different imputation-regression combinations on the training and held-out test set respectively. The best performance on held-out test data is achieved at an R^2 (coefficient of determination) of 0.702 when using MICE to impute each variable conditioned on only highly correlated other variables (correlation ≥ 0.25) followed by using random forest regression on the imputation-completed test results, and demonstrates the presence of substantial information redundancy. Note that the random forests based algorithm, when used in either imputation or regression, tends to overfit. This can be seen by comparing the training-testing performance discrepancies of MissForest with other imputation methods, as well as by comparing that of random forest regressions with other regression methods.

Discussion: To put the above results into context, we randomly shuffled the ESR values. The R^2 between shuffled ESR and original ESR is 0.001 ± 0.000. The $|R^2|$ for imputation-regression on the shuffled ESR all have mean ≤ 0.05 and confidence interval ≤ 0.005. These data corroborated our hypothesis that the ESR provides information in at least some patients that overlaps substantially with the results of other concurrent tests. We selected ESR as a proof-of-concept, as it would likely provide information that substantially overlaps with other common tests. We plan to apply similar techniques to a wide-range of tests and we envision this approach will ultimately provide a useful foundation for clinical decision support. For example, defining a patient-specific "pre-test" distribution of results for each test, given the patient's existing test results, may be informative in deciding which tests to order. In addition, it will be useful to correlate imputed results with clinical information and outcomes to assess the possibility that imputed ESR may actually provide a better assessment of physiologic or pathologic states than measured ESR.

Table 1 Description of explaining variables used for ESR regression.

Variable Description	Variable Description
Patient age	Mean cell volume
Patient gender	Percent monocytes
Absolute basophil count	Percent neutrophils
Absolute eosinophil count	Percent nucleated red blood cells
Albumin level	Absolute nucleated red blood cells
Alkaline phosphatase level	Plasma anion gap
Absolute lymphocyte count	Plasma blood urea nitrogen (BUN) level
Absolute monocyte count	Plasma chloride level
Absolute neutrophil count	Plasma creatinine level
Percent basophils	Plasma glucose level
Plasma calcium level	Plasma potassium level
C reactive protein (CRP) level	Plasma bicarbonate level
Percent eosinophils	Platelet count
Globulin (plasma) level	Plasma sodium level
Hematocrit	Red blood cell (RBC) count
Hemoglobin level	Red blood cell distribution width
Percent lymphocytes	Aspartate transaminase (AST) level
Mean cell hemoglobin	Alanine transaminase (ALT) level
Mean cell hemoglobin concentration	Total bilirubin (plasma) level

Table 2 Regression results with different imputation-regression combinations on training and held-out test data sets respectively. Performance metrics include mean square error (MSE) and coefficient of determination R^2. In MICE-full, imputing every variable is conditioned on all the rest variables. In MICE-sel, imputing each variable is conditioned on only highly correlated other variables (correlation ≥ 0.25). MICE and MissForest are run 100 times and their results are in the format of mean $\pm$ 0.95 confidence interval. Best performance is highlighted with bold face.

Evaluate the Effectiveness of Mobile Health Intervention Program for the Senior Population Suffering from Hypertension and Hypercholesterolemia in Taiwan

Wu M.P, Director, MN[1], Chang P.L, Prof, PhD[2], Lee C.H, MD, PhD[3]
[1]Department of Nursing, Taipei City Hospital, Zhongxing Branch, Taiwan; [2]Institute of Biomedical Informatics, National Yang-Ming University, Taiwan; [3]Department of Surgery, Taipei Veterans General Hospital, Taiwan.

Introduction

The objective of this study is to evaluate the effectiveness of a mobile health program targeting seniors with a high risk of hypertension and hypercholesterolemia. Taiwan has gradually become a country with a high percentage of senior citizens. With changes in diet and living habits, the number of seniors suffering from hypertension and hypercholesterolemia is on the increase. In recent years, the use of mobile medical application for self-healthcare management has been increasing among the senior population. In this mobile Health program, the participants would be learning how to use the mobile phone and the medical healthcare application (App) for updating their relevant personal health records (for instance: measure blood pressure, pause, physiologic index, time of taking medicine, Chronic Disease Management etc.) at home. Call center will send a text message to the participants if any unusual was found in the uploaded data. This medical application system has reached the efficacy of disease prevention, health alert and early treatment by enabling participants to measure and control their own health, thus reducing unnecessary needs for medical consultations, which alternately contributes to the more efficient use of limited medical resources. It is for the aforementioned reasons that this study can be regarded as innovative and influential.

Method

The study samples were selected from residents living in the Shilin District of Taipei City, Taiwan, aged from 50 to 70 year- old adults. All of our participants were physically diagnosed with high- risk of hypertension and hypercholesterolemia. We used a structured questionnaire as our study tool, the contents of the questionnaire including participant background, Chinese version Hypertension & High Cholesterol Management Self- Efficacy Scale Questionnaires and The Summary of Hypertension & High Cholesterol Self- Care Activities Questionnaires. The participants would be taking the mobile application (App) and medical information service integrated course. Following the end of the interventional program, the participants would have to complete assessment at the baseline and there would be a 6-month follow-up with their personal cases.

Results

66 participants (mean age= 61.01) were evaluated throughout a 6- month study period. The results indicated that there were no change in BMI, Triglyceride and HDL-C. In addition, LDL-C slightly dropped. However, the SBP ($p< 0.001$), DBP ($p< 0.001$), Self- Efficacy Scale ($p= 0.031$) and Self- Care Activities Questionnaires ($p< 0.001$) had significant improvement between the baseline and the 6- month follow- up. (Table 1)

Discussion

Reliable instruments were used in this study to measure the effectiveness of the mobile health program with high-risk of hypertension and hypercholesterolemia in elderly population in Taiwan. The related application was tended to have a positive effect on the participants' self- healthcare control and helped them to maintain a higher level of healthy behavior in both physical and mental respects. This mobile health program should have a good effect on hypertension and hypercholesterolemia participants or elderly population. Although there is no statistically significant difference in LDL-C, a slightly progress can be seen from the result of the 6-month follow-up through the intervention of the mobile health program. Furthermore, we can use information relating to medical technology as well as the health education program to build a better health and medical network system in the future so that the senior participants with a high risk of hypertension and hypercholesterolemia can achieve a better quality of life.

Semantic Loss in Consolidated CDA Exports for Meaningful Use Stage 2

Joshua C. Mandel, MD[1,3], John D'Amore, MS[2], David Kreda[3]
[1]Boston Children's Hospital, Boston MA; [2]Diameter Health, Newton MA; [3]Harvard Medical School, Boston MA

Introduction: Stage Two of the Meaningful Use incentive program requires eligible providers and hospitals to use the Consolidated Clinical Document Architecture (C-CDA) to communicate clinical data between electronic health records (EHRs)[1]. As part of a national certification program, EHRs must be capable of producing C-CDA documents that pass specific testing criteria[2,3]. While these criteria are designed to provide a basis for interoperability across distinct electronic health record technologies, they omit several key factors for real-world interoperability. The SMART (Substitutable Medical Applications & Reusable Technology) Platforms team developed the SMART C-CDA Scorecard, a tool to evaluate C-CDA documents for adherence to best practices for interoperability. To assess the utility of this tool and catalog issues affecting real-world interoperability, the SMART Platforms team invited health information technology vendors to participate in a time-limited SMART C-CDA Collaborative.

Methods: We contacted 107 vendors of health information technology to submit a sample C-CDA document with fictional patient data. Forty-four organizations responded to the invitation and 17 technologies submitted at least one C-CDA sample. We evaluated each technology using the SMART C-CDA Scorecard, which grades performance across six domains: general issues, lab results, medications, problem observations, social history and vital signs. For each domain, multiple rubrics examine successful execution of best practices, such as "Vital signs are expressed with Unified Code for Units of Measure (UCUM)." Based on issues identified, we further elucidated error types and frequencies by manual inspection. We shared findings directly with eleven vendors who elected to participate in individual review sessions.

Results: For the technologies examined with the SMART –CDA Scorecard, the average score was 61% with a minimum of 37% and a maximum of 100%. The three most common errors observed in C-CDA submissions were 1) extraneous precision of datetime values, 2) use of erroneous codes from Unified Medical Language System(UMLS) and 3) medications not expressed with RxNorm semantic drug codes (Table 1). Manual inspection and discussion with vendors confirmed observations and provided context for errors.

Discussion: Based on our work, C-CDA documents are likely to omit key clinical information and require manual reconciliation in the second stage of Meaningful Use. In particular, we asw alarming errors in the use of dynamically bound vocabularies such as Systematized Nomenclature of Medicine (SNOMED), Logical Observation Identifiers Names and Codes (LOINC), and RxNorm. We recommend 1) that the certification process of EHRs should incorporate terminology validation when evaluating C-CDA documents, and 2) that producers and consumers of C-CDA documents should routinely implement real-time data quality services to track implementation issues as they occur. In addition, vendors found the SMART C-CDA Scorecard a useful tool in the review of their sample documents, and they expressed interest in integrating this functionality into their internal testing and development process.

Table 1: Error Frequency among 17 Technologies Submitting C-CDA Documents

Best Practice for C-CDA Implementation	Technologies with at least one violation
Sensible date and time precision	14
SNOMED, LOINC and RxNorm validate from UMLS	11
Medications expressed with RxNorm semantic drug codes	11
Lab results encoded in top 2,000 LOINC codes	8
Vital signs expressed with "required entries" template	8
Document uses C-CDA 1.1 templates when applicable	7
Problems encoded in HITSP SNOMED 16,000 subset	7
Problem statuses are internally consistent	6
Vital signs use appropriate UCUM units	6
SNOMED, LOINC and RxNorm display correct names	3
Only structured smoking status observations are used	3
Vital signs are encoded using correct LOINC codes	3
Smoking Status uses correct SNOMED subset	1
Smoking Status uses correct template	0

Patient-initiated secure messaging: Effects on chronic care process and clinical outcomes in a natural experiment

Sean McClellan, PhD, Palo Alto Medical Foundation Research Institute; Mountain View, CA, USA
Laura Panattoni, PhD, Palo Alto Medical Foundation Research Institute; Mountain View, CA, USA
Ming Tai-Seale, MPH, PhD, Palo Alto Medical Foundation Research Institute; Mountain View, CA, USA

Introduction: We studied the effect of patients sending secure electronic medical advice request messages to providers on process and clinical outcomes, among patients diagnosed with diabetes, hypertension, or hyperlipidemia. Prior research conducted in integrated delivery systems has shown substantial benefits of electronic messaging for patient health, but few longitudinal studies to date have examined the effects of implementing messaging in fee-for-service environments, where incentives for providers to use messaging for chronic disease management may differ. To estimate the effect of messaging, we exploited a natural experiment, where a large multispecialty practice in California eliminated a user fee for messaging of $60/year and initiated incentives for doctors to securely message patients about medical advice requests, resulting in increased rates of patient-provider messaging. We hypothesized that patients initiating any messages would have moderately improved process and clinical outcomes relative to others and that intensity of messaging would be positively associated with outcomes.

Methods: Longitudinal observational study from 3/2009-3/2012 using a "clean user" design, in which all patients in the study had activated their online portal before 2/2011, and none had paid to use messaging previously. The study included three cohorts of patients with diabetes (N=4,224), hypertension (N=15,504), or hyperlipidemia (N=21,728), based within a large multispecialty practice in California. Outcomes included both process and clinical measures for blood pressure, HBA1c, and LDL levels. Messaging was measured by whether or not patients initiated any email threads, categorized into quartiles in order to test differences in messaging intensity. The effects of messaging were identified through differences-in-differences analyses using generalized least squares on propensity score-matched samples, to account for the possibility of unobserved differences between treatment and control groups. Outcomes for patients initiating threads were compared before and after sending messages became free to patients, relative to controls. Covariates included patient age, insurance, Charlson score, and number of visits and phone calls to the group, and also characteristics of patients' assigned primary care providers (PCP), including gender, experience, continuity, and department. Standard errors were clustered within patients.

Results: Patients that messaged initiated an average of two threads per year. In multivariate analyses on matched samples, for each cohort, the probability of completing needed tests consistently increased by between 3 and 9 percentage points for patients initiating message threads, relative to controls. For example, in the diabetes cohort, the probability of receiving an HbA1c test increased by 2.8 percentage points (CI: 0.2,5.3) for patients sending only one message/year and by 5.4 percentage points (CI: 2.9,7.9) for patients sending four or more messages/year. However, we found no evidence that messaging was consistently associated with improvements in blood pressure, HBA1c, or LDL levels.

Discussion: By exploiting a natural experiment, we found that initiating secure medical advice requests was associated with clear improvements in the process of care for patients with diabetes, hypertension, or hyperlipidemia, but was not associated with improved clinical outcomes within the first year. Secure messaging may foster patient engagement and compliance above other online portal functionalities, such as reminders. However, improving clinical outcomes may require other interventions.

Analyzing and Comparing Clinical Work Systems with Cognitive Work Analysis: Lessons Learned

James L. McCormack, PhD, Paul N. Gorman, MD
Oregon Health & Science University; Portland, OR

Introduction: Recent studies have shown that information and communication technologies, including electronic health records (EHRs), can negatively impact patient safety, efficiency, effectiveness, and user satisfaction when they are poorly tailored to the local work practices and contexts of ambulatory care. Yet little is known about how independent medical practices choose to handle external clinical information (received in paper, electronic, or verbal forms), and what sociotechnical capabilities and constraints shape these choices. This presentation describes the lessons we learned applying the Cognitive Systems Engineering framework of Cognitive Work Analysis (CWA) to describe and compare four real-world clinical work systems that are used to handle external test results, referral communication, and outside care summaries.

Methods: CWA[1] was used to analyze and compare qualitative data from four independent primary care practices that included 24 unique interviews with providers and staff, and observations from 20 days in the field. They ranged in size from 1 to 8 providers; all used commercial EHRs and had attested to Stage 1 Meaningful Use. We selected CWA for three reasons. First, unlike traditional workflow studies, CWA is a formative approach that analyzes work systems in terms of the domain constraints and capabilities that shape local work practices. CWA also offered a rigorous and systematic framework to describe and compare both social and technical factors including organizational and environmental characteristics and the specific capabilities and limitations of personnel, facilities, equipment, and software. Finally, CWA has been used in industry and the military to inform the design of complex adaptive systems[2], but has rarely been applied in ambulatory care settings; a recent review found only one paper that used CWA in primary care out of a total of twenty-eight healthcare studies[3].

Results: We found that the broad perspective and unique representations offered by CWA provided a systematic framework to describe and compare the relevant constraints and capabilities across four diverse physician practices. Our use of CWA resulted in three considerations for improving the design of processes, artifacts, and technology: 1) Balance the unique affordances of paper, verbal, and electronic media; 2) Prevent technology from becoming a barrier to individual and team situation awareness; and 3) Empower and encourage staff and providers to design, adapt, and evolve local work practices.

Discussion: Our decision to use CWA presented many challenges. First, while books and papers describe the perspective, theory, and the framework, they rarely specify research procedures. Second, in contrast to previous healthcare studies[3], we attempted all five of the analytic stages described by Vicente[1] with limited time and resources. Our broad approach to data collection made it difficult to fully characterize individual cognitive strategies and competencies, the impact of team structure, and the details of specific information artifacts and media. Finally, extension of CWA by researchers and practitioners has created several variations in terminology and representational techniques from which to choose[3]. We will discuss these and other theoretical, methodological, and practical considerations in our presentation.

Conclusions and Acknowledgments: Cognitive Work Analysis, despite the many challenges, is a promising analytic framework for use in informatics studies. Although our application of CWA had several limitations, it succeeded in providing a sociotechnical map of information handling in primary care that could be used in future investigations and to inform the (re)design of processes, artifacts, and technology. This work was supported by pre-doctoral training grants from the National Library of Medicine (T15-LM-7088-18-ST) and the Oregon Clinical and Translational Research Institute (5 TL1-RR-024159-05). Special thanks to Gavan Lintern and Kenneth Funk.

Introduction

Informatics-based strategies to improve quality of care through electronic health records (EHRs) have had mixed results.[1,2] Failure to apply principles of decision psychology and behavioral economics to EHR design may contribute to these equivocal results. Recently, there has been interest in using knowledge from this field to inform design,[3] and EHR design in particular might stand to benefit.[4-6,7] We hypothesized that novel EHR-based clinical decision support (CDS) and automated performance feedback that build on lessons from behavioral economics could improve antibiotic prescribing practices for acute respiratory infections (ARIs) in primary care settings.[8]

Methods

We recruited 342 clinicians from 49 sites in three health systems and provided education in antibiotic prescribing guidelines to all participating clinicians. Each clinic site was randomized in a 2 x 2 x 2 factorial design to receive 0, 1, 2, or all 3 of the following interventions: (1) "Accountable Justifications": upon initiating an antibiotic prescription for an ARI, clinicians were prompted to record an explicit justification that appeared in the patient electronic health record; (2) "Suggested Alternatives": upon initiating an antibiotic prescription for an ARI, clinicians received an order set of non-antibiotic treatment choices; and (3) "Peer Comparison": each provider's rate of inappropriate antibiotic prescribing relative to top-performing peers was reported to the provider periodically by email. We customized antibiotic prescribing measures and decision support specifications to each health system based on preexisting workflow each of the three different EHR systems in use. We created a clinical data research network to manage the peer comparison intervention and monitor data quality and decision support. We measured antibiotic prescribing rates for likely viral ARIs over an 18 month intervention period.[8]

Results

At the time of analysis, participating clinicians had generated 26,783 visits for ARIs that were inappropriate for antibiotic treatment during the 18-month intervention. In these visits, 68% of patients were female, with an average age of 49 years. Adjusting for baseline prescribing rates, clustering, and patient characteristics, clinicians in the control group prescribed antibiotics in 29% of these visits. In comparison, prescribing rates were 21% among providers exposed to Accountable Justifications (relative reduction 25% versus control; adjusted OR 0.66, 95% CI 0.55-0.79); 29% in the Suggested Alternatives group (relative reduction 0%; adjusted OR 1.02, 95% CI 0.80-1.31); and 23% among providers exposed to Peer Comparisons (relative reduction 17%; adjusted OR 0.71, 95% CI 0.55-0.91). There were no significant interactions between suggested alternatives, accountable justifications, or peer comparison.

Discussion

Of the three interventions, the Suggested Alternatives was the least effective, and arguably most similar to conventional CDS tools using a standard alert-based design triggered by the ARI diagnosis. While only subtly different from traditional decision support, the Peer Comparisons and Accountable Justification interventions appealed to professional and social norms, which may account for their greater effectiveness. Additionally, the elicitation of reasoning in the justification process may engage a more deliberative thought system, since documented rationales are visible to others, in contrast to simple warning alerts that are easily dismissed without clear consequence. In conclusion, it is both feasible and effective to incorporate principles of behavioral economics into informatics-based interventions. These interventions may be more effective than traditional clinical decision support.

Supplemental figures

Exhibit 1 - Odds of antibiotic prescribing

Intervention	Odds Ratio	P>|z|	[95% CI]	
Suggested alternatives	1.02	0.854	0.8	1.309
Accountable justification	**0.66**	<0.001	0.555	0.792
Peer comparisons	**0.71**	0.009	0.55	0.919

Alerts for Low Creatinine Clearance: Design Strategies to Reduce Prescribing Errors

Brittany L. Melton, PhD, PharmD[1], Alan J. Zillich, PharmD[2-5], Michael Weiner, MD, MPH[2,4,5], M. Sue McManus, PhD, NP[6], Jeffrey R. Spina, MD[7,8], Alissa L. Russ, PhD[2-5]

Introduction

Creatinine clearance is a common marker for kidney function and is regularly used to determine doses of medications that may be renally cleared or nephrotoxic. The use of alerts for creatinine clearance has been shown to reduce prescribing errors associated with renally dosed medications. However, the manner in which such information is presented can affect the usefulness of the alerts. *The objective of this study was to apply human factors principles to the design of creatinine clearance alerts. We hypothesized that the redesigned alerts which incorporated human factors principles would improve usability and reduce prescribing errors compared to an original alert design.*

Methods

Twenty VA prescribers completed two 30-minute prescribing sessions for fictitious patients in a counter-balanced, crossover design. One session used the original alerts based on the VA's electronic health record system, and the other used the redesigned alerts. Each session involved three medications that required adjustment or cancellation due to reduced creatinine clearance: spironolactone, ibuprofen, and allopurinol. In the original design, the alert was presented prior to any medication selection, while the redesigned alerts appeared only after a renally dependent medication was selected and prescription information had been entered. The redesign also included additional details about potential risks to the patient. For usability, we analyzed video data and asked prescribers to rate the perceived efficiency of viewing related lab results; this item was analyzed with the Wilcoxon signed-rank test. Correct and incorrect actions for each medication were determined *a-priori* and were used to evaluate prescribing errors. We assessed prescribing errors using Wilcoxon signed-rank and McNemar tests. This study was part of a larger investigation that evaluated prescribing outcomes for various types of alerts. Previous literature has shown that 20 participants uncovers about 99% of usability issues for a given software design.

Results

For usability, prescribers did not perceive any difference in the efficiency of viewing lab test results between the two designs ($p=0.113$). However, 9 (45%) prescribers stated that they would ignore the original alerts because they were not in the process of ordering a renally cleared medication at the time the alert appeared. Participants made significantly fewer prescribing errors when using the redesigned alerts compared to the original alerts ($n=26$ and $n=47$, respectively, $p=0.001$). When using the original alerts, 15% of participants made only one prescribing error while 50% made an error for all three medications. However, with the redesigned alerts, 45% of participants made one error and only 1 (5%) participant made an error for all three medications. Prescribing errors were significantly reduced for ibuprofen and allopurinol with the redesigned alerts versus the original alerts ($p=0.008$, $p=0.012$, respectively, for each medication). There was no significant difference in prescribing errors for spironolactone.

Discussion

These results support the hypothesis that applying human factors principles to creatinine clearance alerts would reduce prescribing errors. Although others have noted that alerts should appear early in the prescribing process to reduce interruptions and support workflow, our results indicate that prescribing errors were reduced when alerts appear closer to the time of decision-making, in this case, later in the medication ordering process. Overall, incorporation of human factors principles into creatinine clearance alerts can reduce prescribing errors and thereby improve safety for patients with reduced renal function.

Congestive Heart Failure Information Extraction Framework (CHIEF) Evaluation

Stéphane M. Meystre, MD, PhD[1,4], Youngjun Kim, MS[2,4], Andrew Redd, PhD[3,4], Jennifer Garvin, PhD, MBA[1,3,4]
[1] Department of Biomedical Informatics, [2] School of Computing,
[3] Division of Epidemiology, University of Utah, Salt Lake City, Utah
[4] VA Health Care System, Salt Lake City, Utah.

Abstract: *To help assess heart failure treatment and automatically extract clinical performance measures, we developed a natural language processing application to extract this information from clinical notes at the Veterans Health Administration. This application was evaluated with a corpus of 32962 notes from 771 patients and 98.9% of the patients meeting the performance measure criteria were accurately classified.*

Introduction: Congestive heart failure (HF) is the main cause of hospitalization for patient older than 65 and affects 5.8 million patients in the U.S., with high associated healthcare costs reaching more than $35 billion in the U.S. in 2008. Efforts to improve the treatment of HF and reduce associated costs include performance measures to assess treatment adherence to recommended care. The American College of Cardiology Foundation, the American Heart Association, and the Physician Consortium for Performance Improvement published such performance measures including "Left Ventricular Ejection Fraction (LVEF) Assessment" and "Angiotensin-Converting Enzyme Inhibitor (ACEI) or Angiotensin Receptor Blocker (ARB) Therapy." The ADAHF (Automating Data Acquisition for Heart Failure) project aimed at automating the extraction of such information from clinical notes. Natural language processing (NLP) can be used to extract various types of information from clinical narratives,[1] and we developed such an application to automatically extract clinical information for HF performance measures. The evaluation of the Congestive Heart Failure Information Extraction Framework (CHIEF) when classifying each patient as meeting the performance measure requirements or not is reported here.

Methods: The CHIEF is based on the Apache UIMA framework with modules for each type of information to extract from clinical notes. After text pre-processing (sentences detection, tokenization, part-of-speech tagging), a module extracts mentions and values of LVEF using machine learning (Margin Infused Relaxed Algorithm; MIRA[2]). The next module uses a medication names dictionary with fuzzy matching to extract medication names. Another module integrates RapTAT[3] to extract medication contra-indications or other reasons the patient should not be treated with ACEIs or ARBs. Finally, a last module uses all the extracted information extracted from multiple notes along with clinical note type information to classify the patient as meeting the performance measure or not. A set of rules is used for this last task. For the development and the evaluation of CHIEF, a large corpus of clinical notes from VHA (Veterans Health Administration) patients suffering from HF was manually annotated and split into a training corpus (notes from 314 patients) and a testing corpus (32962 notes from 771 patients). After training with the former, the latter corpus was used for the evaluation reported here.

Results: As presented in Table 1, when comparing the patient classification inferred by CHIEF using rules and the automatically extracted LVEF, medication, and contra-indications information, 98.9% of the patients meeting the performance measure criteria were accurately classified. Most information was accurately extracted. Only reasons for not treating the patient with ACEIs or ARBs were often missed, only detecting about 27% of them at the patient level.

Table 1: Patient level classification results

	Sensitivity	Positive Predictive Value	F_1-measure
Was LVEF assessed ?	1 (95% CI: 0.995-1)	0.990 (0.980-0.996)	0.995
Was the measured LVEF below 40% ?	0.968 (0.946-0.983)	0.952 (0.926-0.970)	0.960
Was the patient treated with ACEI or ARB ?	0.992 (0.981-0.997)	0.885 (0.858-0.908)	0.935
Was there a reason if not treated with ACEI or ARB ?	0.269 (0.199-0.349)	0.907 (0.779-0.974)	0.415
Performance measure met ?	0.989 (0.978-0.995)	0.987 (0.976-0.994)	0.988

Binomial exact confidence intervals used; F_1-measure is the harmonic mean of sensitivity and positive predictive value (with equal weight for each).

Patients Screening for Clinical Trials Using EHR Representation Similarities

Riccardo Miotto[1], Ph.D. and Chunhua Weng[1,2], Ph.D.

[1]Department of Biomedical Informatics, Columbia University, New York, NY, USA
[2]The Irving Institute for Clinical and Translational Research, New York, NY, USA

Introduction

Randomized controlled trials generate quality medical evidence but suffer from longstanding recruitment problems [1]. Existing solutions mostly focus on eligibility criteria processing to facilitate trial search by patients [2, 3] or patient search using electronic health records (EHR) by investigators [4]. An untapped opportunity is using "case-based reasoning" to identify patients similar to known trial participants. This study tested the feasibility of this idea.

Methods

Our methodology framework includes two parts: (1) the participants currently enrolled in a trial are used to estimate a trial representation capturing relevant patterns in the participants' EHR data; (2) other patients are ranked by their EHR data's relevance to this representation: the higher the rank, the more likely are them eligible for the trial.

We identified patients enrolled into 13 clinical trials performed at Columbia University as our gold standard. These trials covered assorted diseases such as Type 2 diabetes, HIV, and multiple myeloma. The number of participants per trial ranged from 3 to 119. We obtained the EHR data for these patients and for about 30,000 other patients selected at random from the Columbia University's clinical data warehouse for design and testing. Data for trial participants were limited to a time period ranging from before the beginning of recruitment to one year after. Our data included patient clinical notes, ICD-9 diagnosis, event codes, and lab values. Clinical notes were pre-processed to extract UMLS-based tags and summarized using topic modeling to reduce the sparseness of the data [5]. Topics were generated over a random subgroup of 10,000 patients using Latent Dirichlet allocation [6].

During evaluation, for each clinical trial, we ran a 2-fold cross validation experiment, where half patients were for training and the other half was for testing, together with the rest of the random sample. The EHR-based trial representation, which was estimated from the training set and then applied to the test set, can be obtained in various ways. In this study, for the sake of simplicity, we considered concepts frequently shared by the trial participants and we averaged the set of their values, where values could represent occurrences for diagnosis and event codes, topic probabilities for notes, and mean result values for lab. Test patients were then ranked according to their similarity to the trial representation. Similarity scores referred to a weighted linear combination of cosine similarities computed over individual data types and ranged between 0 and 1 (with "1" meaning "perfect similarity"). For each test fold we measured (1) the similarity among relevant patients and their similarity to irrelevant patients and (2) the ranks of relevant patients. We then report results averaged over all fold experiments for all trials.

Results

The relevant patients were similar among them (mean similarity of 0.578) and significantly dissimilar with the rest of the collection (mean similarity of 0.129). This confirms that participants enrolled in a clinical trial share some patterns in their EHR data. These patterns can be used to identify new potentially eligible candidates and to separate them from ineligible ones given the large difference in similarity. This benefits the recommendation of potential participants to a trial as showed by the retrieval experiment results reported in Table 1. The weighted combination approach ranked about 65% of the relevant candidates within the top 10 positions. Moreover, for each fold trial, we ranked at least one relevant patient within the top five positions. This is particularly significant because, in an applicable scenario, an investigator would be required to look at only the top of the recommended list to likely pre-screen new potential participants to the target trial.

Discussion

Results demonstrate the feasibility of using EHR representation similarity with participants to expedite patient screening with little additional actions from the investigators. This approach can be used to constantly mine patient data warehouses for discovering new potential participants or it can also integrate strategies matching EHR data and eligibility criteria towards more effective systems. Results were obtained using a very basic training techniques; more sophisticated approaches (e.g., classification, learning to rank, statistical modeling) might lead to better performance. Therefore, we believe this work could also point to new research directions involving the study of novel machine learning techniques to improve the EHR-based trial representation and, consequently, to leverage the trial participant recommendation.

Table 1: Retrieval experiment results in terms of precision-at-10 (P10), mean average precision (MAP), and mean reciprocal rank (MRR). "LwrBnd" refers to results obtained by randomly ranking the test collection, while "UppBnd" refers to the best results achievable if all the relevant documents were at the top of the ranking list. "wComb" is derived using a weighted linear combination of the cosine similarity scores achieved by events, diagnosis, note, and lab values, separately. The other algorithms simply ranked patients according to the similarity values based on only one data type (i.e., only diagnosis, only lab values, only code events, and only notes). These scores were strongly complementary with each other, leading to the significant improvement achieved by wComb.

	Ranking Algorithm	P10	MAP	MRR
Baseline	*LwrBnd*	0.004	0.001	0.005
	UppBnd	0.477	1.000	1.000
Ranking by Data Type	*onlyEvents*	0.046	0.096	0.137
	onlyDiagnosis	0.055	0.135	0.187
	onlyNote	0.106	0.186	0.267
	onlyLab	0.132	0.281	0.374
Linear Weighted Combination of Data Type Similarity	*wComb*	**0.304**	**0.558**	**0.717**

Applying Active Learning to Word Sense Disambiguation in a Real-Time Setting

Sungrim Moon, Ph.D.[1], Yukun Chen M.S.[2], Jingqi Wang B.S.[1],
Joshua C. Denny M.D., M.S.[2,3], Hua Xu Ph.D.[1]
[1]School of Biomedical Informatics, The University of Texas Health Science Center at Houston, Houston, TX, USA; [2]Department of Biomedical Informatics, [3]Department of Medicine, Vanderbilt University, Nashville, TN, USA

Introduction: Statistical natural language processing methods often require large annotated clinical corpora. However, it is time-consuming and costly to create such corpora in the medical domain. Active learning,[1] a technology that actively selects the most informative samples for annotation in an iterative fashion, has been applied to a wide variety of language processing tasks and showed promising results on reducing annotation costs and improving classification models,[2] including clinical Natural Language Processing (NLP) classification systems.[3-6] However, prior active learning studies in medical text processing were simulations using previously annotated data sets. The effectiveness of active learning for building clinical NLP classifiers in a real-time setting has not yet been investigated. In our study, we applied an existing active learning system developed in the general English domain to build word sense disambiguation (WSD) classifiers for clinical abbreviations, and evaluated its performance using real-time annotation experiments by a physician.

Methods: In this study, we used an existing active learning system called DUALIST, [7] which provides an interface between the annotator and learning machine for iteratively annotating samples (ambiguous abbreviations in this case). The system implements an uncertainty-based querying algorithm integrated with a multinomial Naïve Bayes classifier for active sample selection. Figure 1 shows a screen shot of the DUALIST annotation interface for WSD. We tested an Active Learning (AL) mode in DUALIST, which asks an annotator to label a batch of samples (N=5 in this experiment) on the interface, trains/re-trains the WSD model and then actively selects the next batch of informative samples for annotation at the back-end. In addition, we also tested a Passive Learning (PL) mode, which randomly selects samples at each iteration, as the baseline method. We compared AL vs. PL for building WSD classifiers of clinical abbreviations. We selected six frequent ambiguous abbreviations (CA, CC, DM, LAD, PE, and RA) and collected sentences containing these abbreviations from admission notes at Vanderbilt University Medical Center. For each abbreviation, 200 sentences were randomly selected and manually annotated to serve as an independent test set, and the remaining un-annotated sentences were used in a pool for active or passive learners. A physician was asked to annotate each abbreviation at the AL or PL mode, in a random order, for five minutes. We then generated learning curves (plotting the accuracy of a WSD classifier on the test set vs. the time of annotation) for the two learning modes for comparison. The Area under the Learning Curve (ALC) was also reported as a global score for measuring the learning process.

Results: Figure 2 shows the learning curves for the six abbreviations used in our study. In most of the cases, the learning curves of the AL mode were situated above or around those of the PL mode. Table 1 presents the accuracies of the final WSD classifier after five minutes annotation, as well as the ALC scores for different learning strategies. Out of the six abbreviation experiments, AL mode achieved higher final accuracy in five and higher ALC score in four as compared to the PL mode. The AL mode showed an average ALC score of 0.80, while the PL mode achieved an average ALC score of 0.78. The average accuracies were 0.88 and 0.86 for the final classifiers by the AL and PL modes, respectively. The average annotated sample sizes were 99.17 and 128.66 for AL and PL modes, respectively. The average number of re-training iterations in five minutes by AL and PL modes were 22.33 and 27.50, respectively.

Discussion: To the best of our knowledge, this is the first study that evaluates active learning for clinical NLP classification tasks in a real-time setting. We showed that the AL mode outperformed the PL mode for four out of six clinical abbreviation WSD tasks. In the case of the abbreviation RA, AL achieved an accuracy of 0.89 in 1.82 minutes, while PL required 5 minutes for the same task. Thus, AL decreased annotation time by 64% (3.18 minutes). In terms of the size of annotated samples, AL mode used 40 samples while PL needed 116 random samples to reach the same accuracy (a reduction of 66%). The superior performance of AL is more obvious in the early stages of the learning curves. Our findings demonstrated the practical value of active learning in building WSD classifiers.

Informatics for Integrating Biology and the Bedside (I2b2) Clinical Trials (CT) Patient Ascertainment Suite

Shawn Murphy MD, Ph.D. (1,3), Nich Wattanasin MS (2), Vivian Gainer MS (2), Susanne Churchill Ph.D.(2), Issac Kohane, MD, Ph.D.(3)

1 – Massachusetts General Hospital, Boston, MA, 2 – Partners Healthcare, Charlestown, MA, 3 – Harvard Medical School, Boston, MA.

Introduction – The i2b2-CT Software Suite is an informatics tool set designed to facilitate the selection of patients from existing healthcare data (electronic health records) for clinical trials. The i2b2-CT software application may be used as a stand alone application at any single healthcare entity with an i2b2 clinical research data warehouse. It will be linked in March of 2015 through a web based research network to allow identification of eligible patients from multiple institutions through the Shared Health Research Informatics Network (SHRINE).

Methods - An investigator first investigates the feasibility of a putative clinical trial by querying his/her institution's i2b2 instance [1] for the aggregate number of patients meeting selected inclusion/exclusion criteria. If he/she determines that a trial is feasible, the investigator can proceed to requesting a Limited Data Set (LDS) under a data use agreement for rapid patient screening to build a more thoroughly characterized subset of patients to understand if the patients are suitable for the clinical trial [2]. Once the patient population has been adequately reviewed as a limited data set and the clinical trial feasibility is ascertained, the investigator and/or his/her study staff will progress to viewing individual data from each of the patients selected from the LDS review following a full review of the Institutional Review Board to allow access to Protected Health Information for contacting the patients. Access to the data and contact of patients is governed by that institution's current Institutional Review Board (IRB) practices.

Results - The i2b2-CT project developed novel software applications to provide the investigator a friendly, intuitive interface for rapid line by line viewing of digested patient attributes, and the ability to drill deep into a individualized view that can appear very similar to what an electronic medical record could produce by using Substitutable Medical Applications and Reusable Technologies (SMART) [3]. The SMART apps can be customized for each data type, and a collage of these apps can be selected and rendered in a layout that displays diagnoses, medications, and images, and genomics on a specific patient. Thus for even the most novel forms of data or routine data, the display can be adapted and controlled.

Discussion – The i2b2-CT project is used to accrue patients for clinical trials. It is also valuable as a platform for generally validating phenotypes as part of "in-silico" studies that explore associations of phenotypes with the information gathered from samples as in a BioBank. The software can adapt to Patient Surveys and Reported Outcomes as well as routine Electronic Medical Record data. It can be used for multisite trials across institutions using SHRINE [4].

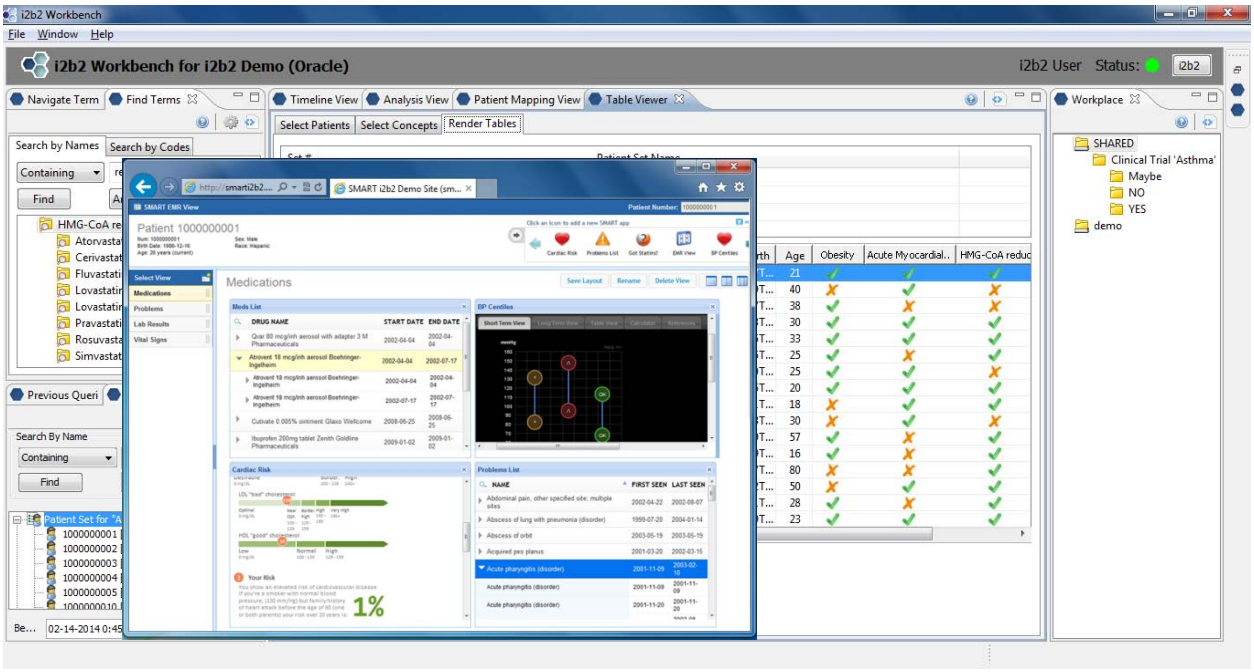

Figure shows the i2b2 Workbench where a patient set is investigated in detail using the customizable SMART electronic medical record view.

Use of Ontologies for Disease Management Clinical Decision Support Systems

Seyed Ali Mussavi Rizi, MD, MHA; Abdul Roudsari, PhD
University of Victoria, Victoria, British Columbia, Canada

Introduction: Ontologies have been used in many different capacities in health information systems. In this study we aimed to perform a systematic review of the literature on using ontologies for disease management clinical decision support systems (CDSS), and development and execution of clinical practice guidelines (CPG) and clinical pathways (CP).

Methods: A systematic review of literature was performed using MEDLINE and EBSCO Academic Search Complete database. "Ontology", "ontologies", "ontological" terms were used as the primary keywords, excluding "gene ontology", and results were combined with searches for terms related to CDSS, CPG, CP using literal and MESH terms. Only papers that presented development and characteristics of an actual system were included, thus any paper that only presented a theoretical approach, details of development of a certain ontology, or review articles were excluded. The selected articles were appraised and compared on the following attributes: the rationale for using ontology in the design; tools and formalism used; clinical usage; issues and challenges; implementation stage; evaluation and follow-up studies. Application of inclusion and exclusion criteria and assessment of articles were mainly performed by the first author (SAMR) in discussions with the second author (AR).

Results: The search strategy resulted in 141 articles. After review of the abstracts, 32 articles published from 1995 up to early 2012 were selected for full review. The articles could be divided into three broad categories: clinical practice guidelines (CPG) (14) clinical pathways (CP) (4), and general clinical decision support systems or expert systems (collectively CDSS) (14). In the CPG group, the general rationale for using ontologies was developing a flexible, reusable, shareable, and computable description of the CPG and domain with some reasoning capability. In the CP group, ontologies were used to describe the CP model, the terms, semantics, relationships, also knowledge about resources, outcome, and variance. The rationale in the CDSS group was more varied and included separation of domain knowledge from solver components, increasing sharing and reusability of components, computing semantic similarity, reasoning and classification capabilities of ontologies, making implicit knowledge explicit, and development of adaptive and personalized CDSS. Protégé family of tools and OWL family of languages were most commonly used as the tool and language for development of the ontologies. Ontology engineering methodology was explicitly identified only in 5 articles. Almost all of the articles presented the results of validation or evaluation of the system, albeit primitive. Only 7 (22%) of 32 systems were deployed at the time of publication.

Discussion: Results of this study show that although ontologies could be useful in developing different types of disease management CDSS, they introduce new challenges. For example, using ontologies to separate domain knowledge and problem solving methods provides means for reusability, rapid development and update of the systems, however it shifts the problem of maintaining rules to maintaining mappings between the components and introduces new problems of incompatible and sophisticated system design with a low tendency for adoption. Another problem in using ontologies in CDSS is the required expertise and interaction between medical experts and knowledge engineers. One study evaluated, and identified that Protégé proved to be unintuitive and difficult to use for domain experts. This observation requires further research to identify the optimal tools, expertise, and composition of teams required for ontology development. Finally, comparing characteristics of the systems reviewed against published guidelines on when ontological methods are the right choice shows that some of the systems reviewed could have benefited from simple rule engines or knowledge bases, rather ontology.

This review has few limitations. First, the term "ontology" refers to different concepts and does not have a universally accepted definition. We used the literal terms for search strategy without further specification which could lead to omission of relevant articles. Second, we only focused on published academic literature which could result in potential exclusion of commercial or proprietary systems that are not described in this body of literature and limit generalizability of the results. Lastly, inclusion, exclusion, and assessment of articles were mainly performed by one author that could introduce bias into the results.

Automated Clinical Trial Eligibility Pre-Screening: Increasing the Efficiency of Participant Identification for Clinical Trials

Yizhao Ni, PhD, Stephanie Kennebeck, MD, Constance M McAneney, MD, Judith W Dexheimer, PhD, Todd Lingren, MS, Qi Li, PhD, Haijun Zhai, PhD, Imre Solti, MD, PhD, MA
Cincinnati Children's Hospital Medical Center (CCHMC), Cincinnati, OH

Introduction and Background

Manual eligibility screening (ES) for a clinical trial typically requires a labor intensive review of patient records that utilizes many resources. Many barriers remain for automated screening and the progress seems to be reaching a plateau[1]. To address these barriers, we assembled state-of-the-art natural language processing (NLP), information extraction (IE) and machine learning (ML) technologies to develop an automated ES system. The objective is to develop a high sensitivity automated pre-screening system to identify patients who meet core eligibility characteristics to markedly streamline and focus the pool of candidates for manual screening.

Data and Method

We focused on clinical trials for pediatric patients who visited the Emergency Department (ED) at CCHMC between 1/1/2010 and 8/1/2012. We collected the eligibility criteria for 13 disease-specific ED clinical trials (inclusion criteria involved one or more diseases). We randomly sampled 600 patients who visited the ED during that timeframe and extracted 15 EHR attributes to represent their clinical status at their dates of visit (Tab. 1). Two physicians then reviewed the chart for each patient and the criteria of the open trials on the patient's date of visit and created a set of gold standard trial-patient matches (Inter Annotator Agreement=96.81%). The physicians reviewed a total of 3061 trial-patient pairs and found 74 matches (average eligible rate 2.42%).

We utilized the state-of-the-art NLP, IE and ML algorithms to build the ES system (Fig. 1). Given a clinical trial and the patient candidates, (1) the system first applied logical constraint filters (LCFs) to rule out ineligible patients based on structured attributes (e.g. age) derived from the trial criteria; (2) the text-based attributes of the pre-filtered patients were then processed, from which the medical terms and assertions were extracted using the clinical NLP tool cTAKES[2] and stored as patient pattern vectors; (3) the same process was applied to the trial criteria to construct the trial pattern vector; in addition, (4) the vector was extended with informative patterns extracted from EHRs of previously enrolled patients using ML techniques so as to capture potential hyponyms (e.g. football, soccer) relevant to the trial criteria (e.g. sport-related trauma) in the patient EHRs; finally (5) IE algorithms matched the trial vector with the patient vectors using TF-IDF similarity and returned a ranked list of patients based on the similarity scores.

We used three evaluation metrics to measure performance: (1) mean average precision (MAP) commonly calculated in information retrieval; (2) workload defined as the number of patients required to be reviewed from the system output to get all eligible patients (i.e. recall=100%); and (3) the recall curve on different cut-offs of the system output. For system comparison, the baseline was used to simulate the process without automated pre-screening. It was implemented by randomly shuffling the patient list for a trial. We then compared its performance with three variants of the ES system that cumulatively integrated the proposed components: (1) LCF that only used the LCF component to exclude ineligible patients and randomly shuffled the rest of the patient list for a trial; (2) LCF+NLP: the ES system specified in Fig. 1 without the ML component; (3) LCF+ NLP+ML: the ML component was also included. To train the ML component, we collected EHRs of 4,202 patients historically enrolled in the 13 trials during the study period and randomly sampled 1% to 100% of the data for training (c.f. Fig. 2.c). None of these additional patients were included in our 600 patient set.

Results and Discussion

Fig. 2.a shows the systems' average performance over all trials. The LCF had good capability in excluding ineligible patients (workload reduction 48%, 49 vs 95 screened patients). However, without information from clinical text, it was unable to match descriptive criteria (e.g. diagnosis) with patients' clinical status. By applying the NLP and IE algorithms on clinical narratives, the LCF+NLP system further improved the performances (workload reduction 86%). For LCF+NLP+ML we observed consistent improvement in performance when more training data was used (Fig. 2.b). In case of 2% training data (85 samples), it outperformed LCF+NLP significantly (Fig. 2.a). This result implied the great potential of ML in boosting the performance of the ES system. Finally the LCF+NLP+ML system (trained on 2% of the data) achieved 90% recall by screening the top 24% of the system output (Fig. 2.c), suggesting that the screening efficiency could be improved by 400% while missing only 10% of eligible patients.

Table 1. Structured (S) and text-based unstructured (US) attributes extracted from patients' EHRs.

Age (S)	Gender (S)	Spoken language (S)
Glasgow coma scale (S)	Vitals (S)	Acuity (1-5, 1:urgent; 5: not urgent) (S)
Patient pregnancy Y/N (S)	Guardian presence Y/N (S)	Chief complaint (US)
Diagnosis (US)	ED clinical notes (US)	Patient medical history (US)
Patient surgical history (US)	Patient family medical history (US)	Patient medication history (US)

An Electronic Patient Safety Checklist Tool for Interprofessional Healthcare Teams and Patients

Kumiko Ohashi, RN, PhD[1], Patricia C. Dykes DNSc, RN, FAAN, FACMI [1, 2], Diana L. Stade[1], Eddy Chen, MD[3], Anthony F. Massaro, MD[4,] David W. Bates, MD, MSc, FACMI[1] Lisa S. Lehmann, MD, Ph.D[1]

1General Internal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Center for Excellence in Nursing Practice, Brigham and Women's Hospital, Boston, MA; [3]Department of Medical Oncology, Dana-Farber Cancer Institute/Brigham and Women's Hospital, Boston, MA; [4]Department of Pulmonary Medicine, Brigham and Women's Hospital, Boston, MA

Introduction: Fragmentation of healthcare poses a threat to patient safety, and leads to inefficient care, which is low value care. Several studies have demonstrated the usefulness of checklists to improve the quality of care such as increasing treatment compliance and reducing complications and medical errors in the clinical setting. In the current model of care, however, physicians and nurses have separate patient care checklists to organize, manage, and hand off critical patient-based tasks. Physicians and nurses do not have integrated checklists to share their documents with each other or with other healthcare providers. The goal of this study is to facilitate and support interaction and communication among all the members of a patient care team by developing, implementing and evaluating an electronic Patient Safety Checklist Tool. Physicians and nurses will enter data into the Checklist Tool and the contents will be shared with multidisciplinary team members and patients and family to review and provide input. The Patient Safety Checklist Tool is an electronically integrated interdisciplinary suite of tools that will incorporate adaptations of existing validated safety checklists for healthcare providers to use during team rounds. Information dashboards can also be generated to provide a better overview of a patient's care for healthcare providers and patients than the current method of tracking a patient's hospitalization. Information will flow from electronic patient platforms to a Rounding Checklist and from the Rounding Checklist to the Care Team & Patient Dashboards. The Patient Safety Checklist Tool would allow all members of a healthcare team to add, edit, and view a patient's safety items (e.g., deep venous thrombosis (DVT) prophylaxis, patient falls, gastrointestinal bleeding prophylaxis etc.) and plan of care (e.g., planned procedures, imaging, labs, family meetings, etc.).

Methods: 1) A problem analysis phase consisted of the following: study team performing workflow observations, document review, interviews with healthcare providers, workflow analysis, team communication, utilization of safety bundles, and to do lists, and nine focus groups. Clinical documentation (e.g. physicians' notes, nursing plan of care, flow sheets, personal to do checklists, and notes on white boards) were reviewed to determine the contents of the Patient Safety Checklist Tool. 2) Using knowledge gained in the problem analysis phase we designed the Patient Safety Checklist Tool**.**

Results: The pilot content of the Patient Safety Checklist Tool is shown in Figure 1. Based on healthcare provider and patient feedback, patient risk/status reminder icons were developed for display in a web-based patient portal with detailed educational contents for patients and care partners. As a first pilot test, we implemented the Patient Safety Checklist Tool to support team rounding, communication, and documentation in a medical ICU.

Discussion/Conclusion: We found that there were some challenges with developing/implementing an interdisciplinary Patient Safety Checklist Tool particularly early on in the process. The key of successful implementation was assigning responsibility for specific content and ensuring completeness to avoid duplicated documentation or missing information. The Checklist Tool has potential to facilitate efficient and collaborative patient management. It allows healthcare providers, patients and families to access to the daily plan of care, and to eliminate patient harms. The checklist tool also focused on specific tasks that are essential to the provision of high quality and safe patient-centered care. Furthermore, there is potential for enhancing communication between providers, patients and families regarding specific patient safety information.

Feasibility of Distinguishing Older Adults with Fall Risk Using Motion Analysis

Amy Papadopoulos, DSc[1], Cindy Crump[1], Christine Tsien Silvers, MD, PhD[1,2], Bruce Wilson[1]; [1]AFrame Digital, Inc., Reston, VA; [2]Children's Hospital Informatics Program, Boston, MA

Introduction. Falls are the leading cause of hospital admissions for trauma in the U.S. and the primary etiology of accidental deaths in persons over 65 years.[1] While it is of great importance to reduce the overall number of falls and fall-related injuries, accomplishing this goal will require more dynamic methods for "getting ahead" of a fall through a greater emphasis on risk mitigation and prevention. One approach is by improving assessment and classification of a person's level of fall risk at any given point in time, along with recognizing on a more dynamic basis when that fall risk increases to enable earlier intervention with preventive measures. The purpose of this study was to establish the feasibility of accurately and unobtrusively determining fall risk using motion data collected from places on the upper body to differentiate between fall-prone and non-fall-prone older adults within a laboratory environment.

Methods. As part of an IRB-approved protocol, 30 subjects (10 young adults; 10 older, stable walkers; 10 older, known fallers) were recruited. For each subject, motion data were collected at Virginia Tech's Locomotion Laboratory using Inertia-Link wireless sensors (LORD MicroStrain, Williston, VT) taped to a battery pack and attached to the left wrist and trunk. The sensors collected both acceleration and angular velocity at those points. An electro-optical motion capture system with Qualysis software captured 100 image frames/second from each of six cameras while subjects walked three times each (1) at a normal pace on a 15.5-meter walkway equipped with force plates, and (2) on a treadmill for two minutes. Data were analyzed using software developed in MATLAB (MathWorks, Natick, MA). Stride time and stride length were computed using data from the optical system and force-plate anteroposterior heel position measurements for a single stride. Sensor data peak-to-peak values were calculated and correlated with baseline stride time. Peak forearm swing angle from the wrist gyroscope and peak acceleration from wrist and trunk sensors were calculated and correlated with baseline stride length. As a means for recognizing stability from only wrist acceleration data gathered while walking, a new method was attempted. This method involves first calculating the vector sum of the acceleration data gathered while the participant walked on the treadmill. The autocorrelation value was then calculated as a 2-second window taken from the beginning of the resultant data was cross-correlated with the remaining resultant data from the same individual. As the window was passed over the data, peaks in autocorrelation were noted, the time between peaks calculated, and the maximum peak value stored. The average time between peaks and the maximum autocorrelation value were used as features alone and together to differentiate fallers from other elderly subjects by using the Mahalanobis distance to determine to which group of data, fallers or non-fallers, the features were closest. Leave-one-out cross validation was used to test the new method, and the areas under the receiver operating characteristic curves (AUC) were determined.

Results. The feasibility of using a socially-acceptable wrist-based device to determine gait characteristics was demonstrated by establishing the correlation between arm-swing time and stride time (0.74 wrist gyroscope, 0.74 trunk acceleration, 0.66 wrist acceleration). Stride length was found not to correlate with the collected sensor values. The possibility of using a wrist-based sensor to differentiate fall-prone from non-fall-prone individuals was demonstrated using the autocorrelation method (AUC of 0.82 for the elderly only, 0.86 for all participants).

Discussion. Wrist acceleration data collected during walking were able to differentiate fall-prone from non-fall-prone individuals. This, combined with the previously established ability to automatically differentiate walking from other activities of daily living,[4] makes unobtrusive fall-risk assessment feasible via a small, wireless wrist device.

Missing Evidence for HIT Transformation in a Review of the Literature

Andrew B. Phillips[1], PhD, RN and Jacqueline A. Merrill[2,3], PhD, MPH, RN
[1]MGH Institute of Health Professions, School of Nursing, Boston, MA, [2]School of Nursing, [3]Department of Biomedical Informatics, Columbia University, NY, NY

Abstract
The complexity of healthcare creates barriers to transformation and inhibits a linear path towards change. This study examined the healthcare literature for evidence of technology transformation applying the theory of punctuated equilibrium (PE). Through an analysis of 477 articles from 2004 – 2012 we found no evidence to support technology transformation in health care. We hypothesize that the system creates barriers to authentic consumer engagement needed for change.

Introduction/Background
The complexities of the contemporary healthcare market create barriers to health technology transformation. Multiple payer-provider relationships and delivery models, the knowledge gap between patients and providers, and the complexities of medicine itself are representative of these barriers. Complexity inhibits a predictable linear path toward transformation. Instead healthcare behaves as a complex adaptive system, where change *emerges*, often exhibiting unexpected patterns with unintended consequences. An understanding of how change occurs within this complex system is important to the evaluation of delivery system reform. The landscape created by our nation's policy emphasis on *adoption* of health information technology (HIT) calls for an investigation of evidence of the transformative nature of HIT in healthcare.

Methods
We conducted an integrative review of the literature to examine published evidence for technology transformation in healthcare. Our framework was Gersick's theory of punctuated equilibrium (PE), which defines three distinct components of market transformation in complex systems: deep structure, equilibrium, and revolution (**Figure 1**)[1]. Five databases (MEDLINE/PubMed, Business Source Complete, Social Science Research Network, Web of Knowledge, and Factiva) were searched for publications from 2004 through 2012. Search terms encompassed multiple meanings for "technology" and "transformation" using MESH terms, key words, and free text. The Web of Knowledge database was used for an ancestry search on three foundational articles describing technology transformation and punctuated equilibrium in markets. Factiva was a source for relevant articles in the popular press. Descriptive and evaluative data were extracted and coded based on a uniform classification schema developed from Gersick's PE framework. Interator reliability between 3 coders was calculated for a subset of the data. Directed content analysis was used to evaluate and synthesize the coded data.

Results
From a total of 4,166 candidate publications, 477 met the study's inclusion criteria. 202 addressed Deep Structure, 224 Equilibrium, and 147 Revolution. Interator reliability was 0.73. Across the three components of PE ten themes were identified. The themes, descriptions and publication counts are summarized in **Table 1**: variations in the environment; market complexity; regulations; flawed risk and rewards; theories of acceptance and diffusion; barriers; ethical considerations; competition and sustainability; environmental elements, and internal elements.

Discussion
While there may be unpublished evidence pertinent to the study's conclusions not identified by this review, the 477 publications described a system tolerant only to incremental change. Contemporary technologies, workflows, imbalances, disparities, and system structure suggest a risk adverse environment with little movement toward actual system transformation. The theory of PE posits the need for *disruption* to counteract the resistance generated by known market characteristics (deep structure) in the absence of a clear superior alternative. We found no evidence of disruptive innovation. Instead, we found elements of deep structure perpetuating an equilibrium state of market fragmentation (e.g. vendor defense of market share creates a barrier to interoperable, user-responsive systems) and resistance to potentially transformative paths (e.g. sensible regulation or uniform standards). Our review identified reinforcing factors including uncertainties associated with highly variable delivery models and reimbursement systems, and inequitable returns on investment. Our nation's reform policies specifically were designed to avoid disrupting the employer-based health insurance system and to encourage incremental HIT adoption. Our findings, in concert with examples from other markets, suggest that consumers are critical drivers of transformation by demanding technologies and unrestricted access to data to use *as they wish* versus *as prescribed* by system gatekeepers who perpetuate market equilibrium.

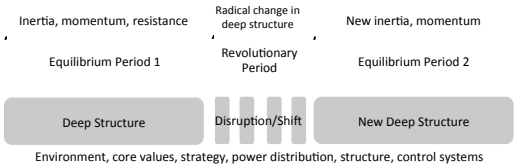

Figure 1 - Three components of Gersick's theory of punctuated equilibrium (deep structure, equilibrium and revolution)[1]

Table 1 - Summary of the Ten Themes Identified in the Literature by Punctuated Equilibrium Component. *Data sources can reflect more than one PE component or theme and not all data sources discussed a specific identified theme.

Identified Theme	Description	N*
Deep Structure		**202**
1. Variations in the environment	The environment of healthcare is defined by factors that influence the adoption and use of HIT, including provider location, size, and HIT vendor capabilities.	85
2. Market Complexity	Healthcare operates within a complex environment characterized by patient confusion, multiple social interactions, data complexity and complex reimbursement systems.	27
3. Regulatory	Regulations guide privacy and security, reporting, reimbursement, liability and standards.	43
4. Flawed Risk and Reward	Incentives to adopt HIT are flawed; inure more to payers and patients than to providers adopting the systems. Fee-for-service reimbursement norms create further disincentives.	24
5. Theories of Acceptance and Diffusion	Several models help describe the patterns of adoption and diffusion of technology within healthcare, including the Technology Acceptance Model and the Diffusion of Innovation theory among others.	27
Equilibrium		**224**
6. Barriers	Data sources highlighted the cost of HIT, lack of human and capital resources, and resistance to change from practitioners as barriers to transformation.	134
7. Ethical Considerations	Ethical considerations contributing to equilibrium include an obligation for technology to do no harm, benefit everyone and not limit ability to practice autonomously.	5
8. Competition and Sustainability	The market economy of the US demands a value driven business case for HIT adoption.	34
Revolution		**147**
9. Environmental Elements	Patient engagement and new models of care represent potential influencers of revolution within healthcare.	74
10. Internal Elements	Change requires effective management, practitioner champions, a shared vision, and a favorable organizational culture.	66

Automated Operative Skill Assessment Using IR Video Motion Analysis

Mihail Popescu, PhD, Christopher Cooper MD, Stephen L. Barnes, MD, FACS
University of Missouri, Columbia, MO

Abstract

One of the greatest challenges encountered during surgery training is objective evaluation of the acquired interventional skills. Expert evaluation by direct observation is subjective and costly. Our automated evaluation method is based on placing IR reflective markers on the surgeon's arms and hands and capturing motion using a Vicon system. The evaluation is performed by comparing the hand traces of a trainee to those of an expert surgeon.

Introduction

As operative interventions become more complex and diverse, acquiring the appropriate skills has become increasingly difficult, especially for low volume, high acuity procedural training. One of the greatest challenges encountered during procedural training is the objective evaluation of the acquired skills[2]. Various computerized methods have been investigated for skill assessment: electromagnetic sensors[2, 3], video camera and a set of surgical gloves with color coded fingers[1] and kinematic measurements recorded by a da Vinci surgical robot[4].

Method and Preliminary Results

We used a Vicon Tracker (www.vicon.com) and gloves with IR reflective markers to simultaneously track and visualize the motion involved in operative procedures. An example of a surgical procedure and its Vicon capture is shown in figure 1. There are 7 Vicon cameras in the environment (one circled in the middle-upper portion of figure 1.left) which make the caption procedure robust to occlusions. In figure 1.left, 5 IR markers are placed in key positions (shoulder, elbow, wrist, back of the hand and index finger) on each arm of a resident surgeon that performs the procedure. In figure 1.middle the marker positions are shown in 3D using a "ball-and-stick" representation.

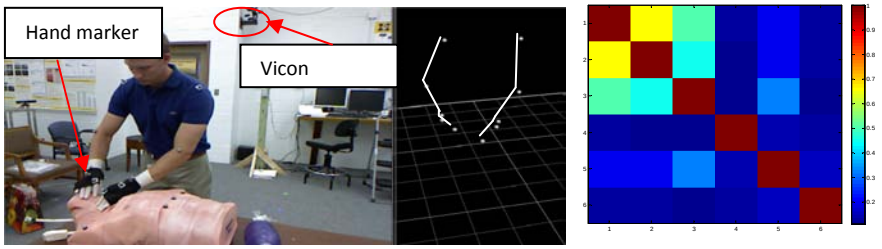

Figure 1. Surgical procedure captured using Vicon (left). 3D arms representation (middle). Similarity matrix for 6 cricothyroidotomies (right)

A cricothyroidotomy was performed 6 times by an experienced senior resident surgeon and instructor of the procedure in our simulation center. The first 3 repetitions ("good") were performed in conformity with the established procedure, while the last 3 ("bad") were conducted in an erroneous fashion. We used a procrustes analysis[5] approach to compute the similarity between two procedures (repetitions) based on the recorded marker traces. The result is shown in figure 1.right. We can see that the similarity between the first 3 repetitions (1, 2, 3) is higher than 0.5, while none of the "bad" ones (4, 5, 6) is more than 0.3 similar to any of the "good" ones. If a library of operative procedures were available, we could use the similarity approach to automatically assess the degree to which a new operative procedure is compliant (or not) to the ones from the library.

Conclusion

This preliminary experiment allows us to conclude that it is possible to automatically assess surgical skills using Vicon video data analysis through a comparison to expert performance.

Unsupervised Time-Series Clustering for Identifying Uncontrolled Type-2 Diabetic Patients

Patric V. Prado, B.S.[1], Chunhua Weng, PhD[2]
[1]Columbia University Mailman School of Public Health, New York, NY;
[2]Columbia University Department of Biomedical Informatics, New York, NY

Introduction

The Health Information Technology for Economic and Clinical Health (HITECH) Act, as part of the American Recovery and Reinvestment Act (ARRA) of 2009, has widened the adoption of Electronic Health Records (EHRs), ensuring the availability of a vast amount of potentially useful clinical information.[1,2] It is imperative to develop analytical methods to make sense of regularly collected EHR data and to generate actionable knowledge for clinical decision support. An example application is to identify patients with uncontrolled medical conditions and recommend them for care to clinicians. This study contributes an unsupervised time series clustering analysis method for identifying uncontrolled diabetics using three lab variables: A1C, Creatinine, and blood glucose values.

Methods

De-identified Hemoglobin A1C, Creatinine, and Glucose values were extracted from EHRs for 26,120 patients. We performed record deduplication and removed records with missing values. The dates associated with each lab value were converted to numerical distance in days from the first visit that recorded an A1C value. These dates were then binned into 120 days (to reflect the American Diabetes Association (ADA) recommendations for testing)[3], A1C (and later Creatinine) values which occupied the same 120 day period were averaged, and missing values were linearly imputed between two real data points. A distance matrix was calculated using a first order discrete wavelet transform for every patient's time series of values and then clustered using partitioning around medoids.[4,5] Using a silhouette width metric, the optimal number of clusters was estimated.[6] Glucose plasma values were similarly binned and average glucose values per time period were compared against A1C controlled/uncontrolled diabetic grouping. The data was then explored and intrinsically evaluated through plotting cluster group means and standard deviations, as well as using density plots to characterize total data distribution, weighted averages, and the proportion of every patient's A1C and Creatinine values under a cut-off signifying controlled diabetes or 'normal'. We chose 7 as the cutoff for A1C (signifying control), as recommended by the ADA standards.[3] As the value for normal Creatinine level is dependent on race, age, and gender[7]; the optimal cutoff was calculated using ROC analysis.

Results

Diabetics were clustered into controlled and uncontrolled A1C groups, with values discriminating around the ADA recommended 7% A1C value without any input as to its significance (**Figure 1**). 98.9% of the 'uncontrolled group' had their total average A1C value above 7% and 84.0% of the 'controlled group' had total values below 7% (signifying control). The proportion of patient A1C values < 7% were also calculated and graphed (**Figure 2**). About 92.6% of the uncontrolled group had less than 49% (ROC defined) of their values < 7%, while 89.1% of the controlled group had more than 49% of their values <7%. When the analysis was carried out to 20 time-points, similar results were observed. The total average Creatinine value showed the best separation between groups by the ROC defined 1.05 value (Sensitivity 95.7%; Specificity 95.92%) (**Figure 3**). There seemed to be no association between uncontrolled A1C and Creatinine values, perhaps due to data incompleteness. After expanding the analysis to include all patients, 3 clusters were prominent: a controlled group (values<1, classifies 98.4% correctly), uncontrolled group (>1, 77.8%), and a small but significant super uncontrolled group (> 2.22, 84.76%) (**Figure 4**). The glucose values, collected during the same time period as the A1C values, showed that 73.94% of the uncontrolled group had average glucose values above 154 mg/dL (corresponding to 7% A1C) and 63.66% of the controlled group had average glucose values below 154. The lack of higher correlation between glucose and A1C warrants further investigation and may be because these records are not complete and are obtained at point of care.

Discussion

These preliminary results show the promising use of time-series clustering methods for the identification of clinical groups that are reflective of more general patterns in laboratory values. As some studies show[8,9], because of the limited reliability of some point of care laboratory tests, general trends may be more clinically valuable than isolated individual measurements. Furthermore, the clustering of these patients along clinically significant values also show promise in the future utility of such a method with applications generalizable to other laboratory values and diseases.

[1]Baylor Scott&White Health - Dallas, Texas

Introduction

More hospitals are implementing Bar Code Medication Administration (BCMA), which has been shown to reduce medication errors by as much as 40%[1]. The potential high cost ($40,000 per BCMA bed[2]) and difficulties in implementation (resolving coordination challenges[3]) led our organization to use human factors specialists in developing a checklist to guide go-live preparation and readiness assessment efforts. The checklist was intended to be widely disseminated to every unit at every hospital in the system, used by staff not formally trained in human factors and help avoid workflow barriers and resulting workarounds via encouraging proactive evaluation of units.

Methods

Two of the organization's fourteen facilities had implemented BCMA, with the 12 remaining required to go-live within a constricted timeframe in order to meet requirements for Meaningful Use attestation. Therefore, the system was in need of a tool to quickly determine the order in which the facilities would go-live with BCMA. However, due to variances in the purchase and installation of hardware, an assessment of each facility's current state was required in order to inform the go-live timeline. It was determined that a checklist, which could be completed quickly with little training, was an ideal tool. To that end, a human factors specialist employed multiple methods in order to determine the most critical elements in need of evaluation for go-live feasibility. First, a contextual inquiry was performed on multiple units already live with BMCA in order to identify workflow challenges and better understand key barriers to efficiency (e.g., having adequate space close to the computer to spread out medications while scanning). Secondly, time and motion studies were conducted in order to quantify workflow before and after BCMA implementation, which allowed the system to evaluate the impact to nursing efficiency created by the additional steps needed for BCMA (e.g., log in to each inpatient room computer prior to scanning). Third, a cognitive walkthrough identified bottlenecks in workflow (e.g., halting the scanning process to interact with computerized alerts). Finally, staff surveys and semi-structured interviews provided subjective assessments of workload and opportunities for improvement. Based on these studies, an infrastructure readiness assessment checklist (Fig 1) was created. The checklist, completed by unit nursing managers, consisted of 15 items that covered three domains of BCMA: inpatient rooms (e.g. placement of computers installed at the bedside), medication rooms (e.g. mapping and evaluating nursing workflow for medication retrieval) and workstations on wheels, WoWs, (e.g. assessing environmental constraints for WoW utilization). The checklist reflected known barriers identified from the studies and previous go-lives in an attempt to proactively avoid negative impacts to staff workflow by having each facility assess the most commonly encountered issues: the technology, the staff, policies and needed education.

Results

The checklist was well-received by the 12 facilities in helping to understand potential challenges in BCMA implementation. It was viewed as an effective method to incorporate the human factors findings with lessons learned from previous go-lives and determine what each facility needed to accomplish in order to proactively counter known barriers created by BCMA go-live. Our organization decided to use the checklist to help evaluate the readiness of each facility by summing all 'yes' responses to checklist items for each unit, as one data source for determining the order in which facilities would go-live with BCMA.

Discussion

The checklist approach was an effective way to incorporate human factors into preparation of BCMA go-live. The checklist may be used by those with only basic awareness training in human factors (i.e. not formally trained) and may be widely deployed for all BCMA areas and can help organizations prevent negative impact to staff workflow and threats to safety resulting from workarounds created by suboptimal implementation strategies.

BCMA Implementation Infrastructure Readiness Assessment Checklist

Instructions:

The Baylor Health Care System BCMA Implementation Readiness Assessment Checklist is comprised of 3 sections of concerns: inpatient rooms, medication rooms, and workstation on wheels (WoWs). In order to better assess the readiness of your facility's infrastructure for go-live, we ask that you complete this checklist for each care area where BCMA will be utilized (one checklist per care area).

Scoring:

For each 'Yes' response, a point is given. There are no points awarded for a 'No' response. In order to calculate a score for each section, simply total all 'Yes' responses and fill in the associated 'Score' cells. The total number of 'Yes' values can be summed to create a global score when all sections are complete. The maximum score is 15 (the maximum score for each section is 5); with a higher score indicating a more thorough BCMA infrastructure assessment.

Facility: _____

Area of Care (please circle one): Med/Surg Tele ICU NICU PACU L&D Postpartum Dialysis

BCMA Implementation Infrastructure Readiness Assessment Checklist	Yes	No
Inpatient Rooms (for workstations installed at the bedside)		
Has *every unit* been evaluated for an installation location individually, including isolation rooms, accounting input devices (e.g. dongle, mouse, keyboard)?		
Have mock-up BCMA workstations been evaluated in the different identified locations and use scenarios evaluated (e.g. facing the Pt, avoiding family/visitors, etc)?		
Has the ergonomic adjustability of the BCMA workstation been considered?		
Does the area immediately surrounding the BCMA workstation contain adequate space for users to spread out and scan, prepare (e.g. crush), and sort medications?		
Have alternative computers been secured for situations in which the primary BCMA workstation is broken or malfunctioning?		
	Score:	_____
Medication Rooms		
Has the workflow of how nurses retrieve medications been mapped and evaluated?		
Was the option of profiling the Omnicells evaluated?		
Is there a process for storing medications that are not profiled in the Omnicell?		
Is a computer workstation readily available and located next to the Omnicell?		
Has the storage and charging processes of the BCMA scanners been evaluated?		
	Score:	_____
Workstation on Wheels (WoWs)		
Has the need for a WoW, environmental considerations (e.g. door width, in-room space, carpet halls, etc), and *all* Wow : staff ratios been evaluated (i.e. RN and RT)?		
Have the WoW requirements *of each unit* been evaluated (e.g. battery charging stations, extra batteries, WoW storage, network connectivity, etc)?		
Have infection control issues (e.g. disinfecting the device) been evaluated?		
Do the WoWs have adequate space for medication preparation (e.g. crush), administration (e.g. scanning), and storage (e.g. lockable drawers)?		
	Score:	_____
	Global Score:	_____ **out of 15**

Facilitating Optimal Patient & Family Engagement in Meaningful Use Stage 3

Jaclyn Rappaport, MPP, MBA [1]; Sara Galantowicz, MPH [1]; Anisha Illa, BS [1]; Andrea Hassol, MSPH [1], Charles S. Sawyer, MD, FACP [2], Jean Adams, RN, ACIO [2]; Sidney N. Thornton, PhD [3]; Shan He, PhD [3]
[1] Abt Associates Inc., Cambridge MA; [2] Geisinger Health System, Danville, PA
[3] Intermountain Healthcare, Salt Lake City, UT

Background: The Centers for Medicare and Medicaid (CMS) Electronic Health Record (EHR) Incentive Program incentivizes providers to adopt standards for "Meaningful Use" of certified EHR Technology. The Meaningful Use program is tiered into stages: Meaningful Use Stages 1 and 2 have entered implementation; objectives for Meaningful Use Stage 3 (MU3) are currently being developed by the Heath IT Policy Committee (HITPC), with a Notice of Proposed Rule-Making to be released in 2014. In partnership with the HITPC, the Agency for Healthcare Research and Quality (AHRQ) funded twelve projects to provide feedback to the HITPC to inform development of MU3 objectives; we report here on one of these AHRQ projects. Abt Associates Inc., in collaboration with Geisinger Health System and Intermountain Healthcare, focused on pilot implementation of select MU3 objectives and criteria. This presentation addresses objectives in the *Patient and Family Engagement* domain, which include: patients being able to "send summary of care documents to designated recipients"; to submit "patient-generated health information" online, and to "allow providers to receive, review, respond… and record patient-generated health data".

Methods: The two health systems pursued implementation of select MU3 objectives, customizing their HIT systems when necessary. Researchers held a series of bi-weekly, semi-structured telephone interviews with informatics leaders from both partner health systems over the course of five months to discuss implementation experience. They tracked and coded the qualitative data to identify and elucidate emerging themes. This process yielded: recommendations to improve the language of the MU3 objectives; recommended vendor functionality to support MU3; suggested evaluation metrics (including exemptions) for the objectives, and ways organizations could maximize the value of the objectives relative to their own strategic priorities. The bi-weekly calls with partners were supplemented by a one-time panel of health IT leaders from health systems across the national landscape.

Results: We found that integrating patient generated information into EHRs and information exchange poses significant challenges in terms of (1) validating the identity of the patient and their providers; (2) adjudicating and reconciling patient-provided content with existing electronic medical records, and documenting an existing patient-provider relationship; (3) obtaining and documenting patient authorization for exchange of their electronic medical information and (4) engaging patients meaningfully. The final report offered feedback to federal officials for consideration, including: ensuring patient-generated content is properly identified and reconciled into the medical record and authorized for sharing with health care teams; supporting a variety of methods for identifying patients, and for providers, using a national directory; and allowing patients to easily and securely access forums in which to exchange information about their healthcare (e.g., SMS communication or mobile applications on smart phones) with clear, patient-friendly instructions for doing so. EHR vendors, Health Information Exchanges, and other HIT service providers will all need to play a role in developing technologies and platforms supporting this evolution.

Discussion*:* The experience of MU1 and MU2 implementation underscores the need to elicit feedback from the field as part of MU3 rule-making. The goal of *Patient and Family Engagement* objectives should be to provide these stakeholders with accessible opportunities for communication, coordination and decision-making regarding their health care. Feedback on MU3 implementation highlighted that increased complexity in MU3 *Patient and Family Engagement* objectives will require that entry, validation and exchange of data using electronic tools be increasingly simple, accessible and secure. Healthcare providers, policy-makers, and vendors/ HIT service providers will need to collaborate to create innovative solutions to achieve these outcomes.

Introduction

Recent outbreaks and deaths caused by gram-negative rod multidrug-resistant organism (GNRMDRO) "superbugs" such as carbapenem-resistant *Enterobacteriaceae* (CRE) among hospitalized patients have elicited national attention. The Chief Medical Officer of England warns that antibiotic resistance could set health care back to the early 19th century. Unfortunately, in electronic health records and, especially, health information exchanges, microbiology culture data are often, in whole or in part, unwieldy text blobs, unsuitable for decision support and unanalyzable even for retrospective studies. The principal informatics problem is that most microbiology messages are not structured in standard HL7v2 format by the hospitals that send data; the messages and the database records take on a wide variety of forms and content. In consultation with infection preventionists (IPs) from diverse hospitals, our objective was to build a regional network to deliver alerts when a patient with a history of GNRMDRO is admitted to a hospital or emergency department (ED), to hasten initiation (when appropriate) of contact isolation.

Methods

We parsed data from 27 hospitals to build 1) an HL7v2 correction engine that deals with incorrect microbiology message structure and content, 2) an admission/discharge/transfer message processor with "global" identity matching, 3) decision support to identify superbugs of interest, and 4) secure email alerts to the IPs at the admitting institution. The HL7v2 correction engine builds upon our thorough review of the inbound HL7v2 structure/content patterns; it also uses open-source and project-tailored natural language processing to parse key data elements needed for the alerts: organism, antibiotics tested, minimum inhibitory concentrations, susceptibility interpretation, body source of the culture, and health care facility where drawn. The five GNRMDRO categories are 1) *Enterobacteriaceae* positive for extended-spectrum beta lactamase (ESBL-E), 2) CRE, 3) *Pseudomonas* resistant to 3 of 4 antibiotic classes, 4) *Acinetobacter* resistant to 3 of 4 antibiotic classes, 5) other GNR with pan-resistance. Because our method deals with microbiology data in general, we are also poised to send alerts for patients with MRSA and Vancomycin-Resistant Enterococci (VRE), and we can deal flexibly with other pathogens. We report here on the first 6 weeks of alerts. The 6 weeks were preceded by a 17-week run-in period in which the microbiology HL7v2 correction engine began generating its registry of patients. We were particularly interested in patient cross-over between institutions.

Results

In the first 6 weeks of the email alerts, the IPs were alerted to 63 distinct patients: 41 admitted to EDs, 21 to inpatient wards, and 1 to a pre-operative unit. Five distinct hospital systems were alerted, for patients admitted to 15 distinct hospital campuses. The GNRMDROs in the alerts were ESBL-E (N=53 [84%]: 46 *E coli*, 5 *K pneumoniae*, 1 *P mirabilis*, 1 *C freundii*), CRE (N=7 [11%]: 6 *K pneumoniae*, 1 *S marcescens*), *Pseudomonas* (N=2 [3%]), and other (N=1 [2%]). Body sources were urine 49 (78%), blood 6 (10%), wound 4 (6%), and 1 each for bronchoalveolar lavage, sputum, bile, or missing. For 19 (30%) of 63 patients, the admitting hospital system was different from where the GNRMDRO culture had been drawn. These 19 reflect 15 distinct pairs of "from, to"

locations {from the culture location, to the subsequent admission location}. Precision was 62/63, 98.4% (95% CI 95.4-100%). One patient had a correctly-parsed HL7 message with *E coli* ESBL, but the hospital sent a subsequent HL7 for the same culture, without ESBL.

Conclusion

Even in just 6 weeks, the amount of cross-over between health care facilities -- by patients colonized or infected with dangerous GNR superbugs -- is striking. The IPs find the alerts to be valuable, especially when the culture was from a hospital system different from the admitting institution. Based in part on a previous (VAX) version of MRSA and VRE email alerts in our region, this microbiology data "push" application may markedly hasten placement (at the admitting hospital's discretion) of relevant patients into contact isolation, and thereby may contribute to reducing the spread of life-threatening bacteria. Future plans include MRSA and VRE alerts, and analyses of recall and cost-effectiveness.

Successful Calculation of Kidney Failure Risk Using the Consolidated Clinical Document Architecture Standard

Lipika Samal, MD, MPH[a,b], Adam Wright, PhD[a,b], John D. D'Amore, MS[c], Beatriz Rocha, MD, PhD[a,b,d], David W. Bates MD, MSc[a,b,d]

[a]Brigham and Women's Hospital, Boston, MA, [b]Harvard Medical School, Boston, MA, [c]Diameter Health, Inc., Newton, MA, [d]Partners Healthcare System, Boston, MA

Introduction/Background

In order to deliver efficient, safe, and high quality patient care, electronic health records (EHR) must support chronic disease management. EHRs can improve disease management through clinical decision support (CDS). Today, most CDS is locally deployed within EHRs which requires specialized knowledge of EHR database structure and terminology. The limitation of this approach is that CDS tools can neither be operated independent of an EHR nor transported across practices. Another approach is to extract clinical information from the EHR and to input the data into CDS applications separate from EHRs.

Stage 2 of Meaningful Use (MU2) requires that 10% of transitions of care be accompanied by an electronic exchange of a summary document. [1] This summary of care record must conform to the Consolidated Clinical Document Architecture (C-CDA) standard. The move toward using standardized structured clinical documents brings two modernizations: 1) consistent tagged format and 2) consistent use of national vocabularies. Due to MU2, there will soon be widespread production of C-CDAs which can provide the clinical data necessary to drive CDS. We sought to develop an application to predict kidney failure risk using a C-CDA as input.

Methods

We identified a validated risk prediction model for kidney failure and implemented it as a browser-based application utilizing three open-source javascript libraries (Bluebutton.js, JQuery, and JQuery UI).[2] This application parses C-CDA documents, extracts the appropriate laboratory and demographic data, calculates both estimated glomerular filtration rate (eGFR) and kidney failure risk, and finally provides clinical decision support to the end user (Figure 1).

We tested the application using sample C-CDAs from five MU2 certified EHRs (Table 1). We manually added appropriate laboratory results to these five C-CDAs. Then, we ran further tests using five C-CDAs from the Partners EHR. The laboratory values were added to these additional test patients in the same manner as if they were generated by the laboratory information system for real patients. We compared the results for both sets of test patients against a calculator available as an online supplement to the risk prediction model.[2]

Results

We found complete agreement between risk estimates calculated manually and risk estimates calculated by the C-CDA application (Table 1).[2]

Discussion/Conclusion

We have demonstrated that a browser-based application can successfully calculate kidney disease risk by using a C-CDA as input. The application was created using open source libraries, an open repository of C-CDAs, and a risk prediction model from the biomedical literature. It can either be locally deployed on a device or be provided as a service.

We addressed several challenges during development. One challenge was to extract laboratory values which have multiple LOINC® codes. For example, eGFR may be calculated by two different equations and each has a different LOINC® code. Another challenge was that the application did not extract serum bicarbonate from a basic metabolic panel. We determined that the basic metabolic panel includes total carbon dioxide, rather than serum bicarbonate, as most clinicians refer to it. Further testing is needed to ensure all relevant concepts are appropriately mapped. A limitation is that the application has only been validated with laboratory results from the Partners laboratory information system. However, a strength of the application is that it can integrate with many potential clinical workflows since it uses common web standards. Therefore it can be validated across EHRs and institutions.

In a broader context, this C-CDA input method allows CDS development and dissemination disjoint from EHR vendor functionality and priorities. The adoption of data standards in MU2 makes possible application development for diverse clinical settings and purposes, even outside of the healthcare system.

Background

As EHR adoption increases throughout the United States, more data are becoming available for outcomes research and population monitoring.[1] Missing data in the EHR not only increase the risk of medical error, but also decrease EHR data quality for researchers, health systems and public health practitioners.[2] Missingness can occur in many ways. Data may appear missing because the provider did not collect information, information is recorded in a different part of the record than expected, data are in an unstructured field, or data are only entered in the paper record.[3,4]

The New York City Department of Health and Mental Hygiene (DOHMH) and City University of New York School of Public Health are developing the first EHR-based citywide chronic disease surveillance system, the NYC Macroscope, featuring key prevalence, treatment, and control indicators across 7 domains. The Macroscope is built on "the Hub," a distributed query network that includes 700 practices using one EHR product. Queries are run nightly and aggregate count results transmitted back to DOHMH. We examined missing data to quantify differences by indicator and patient population that could introduce potential bias.

Methods

For New York City residents aged 20 to 100 years who visited a Hub primary care provider in 2012 we calculated the percentages that had the following elements missing in 2012: blood pressure, smoking status, and total cholesterol lab results. To reflect national recommendations, only men 35 years and older and women 45 years and older were included for cholesterol. The percent of missing blood pressure and cholesterol was also calculated separately among those with diagnosed hypertension and hyperlipidemia, respectively.

Results

Among adults aged 20 to 100, recorded blood pressure was missing for 4.6% of patients, but only missing for 2.0% of those with an additional diagnosis of hypertension. For men 35 to 100 and women 45 to 100, cholesterol was missing for 45.5% of patients, but only missing for 32.0% of those with an additional diagnosis of hyperlipidemia. Among adults aged 20 to 100, smoking status was missing for 33.8% of patients.

Discussion

The amount of missing data varies widely across elements of the EHR. Blood pressure documentation was nearly universal, while cholesterol lab values were missing for almost half the patients recommended to have cholesterol screening. This discrepancy may be explained by a short lab lookback window (only 1 year when the screening recommendation is every five years) and the inability of some practices to receive lab results electronically. Higher risk patients had more data present in the record, which may reflect both more attention by providers and more frequent patient visits. These findings indicate that jurisdictions looking to use EHRs for population health monitoring may have the most success using more complete areas of the record like vitals or focusing on high risk populations that frequently utilize care.

Identifying Plausible Adverse Drug Reactions Using Knowledge Extracted from the Literature

Ning Shang, MS[1], Hua Xu, PhD[1], Thomas C. Rindflesch, PhD[2], Trevor Cohen, MBChB, PhD[1]

[2] National Library of Medicine, Bethesda, MD

INTRODUCTION Pharmacovigilance involves continually monitoring drug safety after drugs are put on the market [1]. To aid this process, automated methods for identifying strongly correlated drug/adverse reaction (ADR) pairs from data sources such as adverse event reporting systems or Electronic Health Records have been developed [2,3]. These methods are generally statistical in nature and do not draw upon the large volume of knowledge embedded in the biomedical literature. In this paper, we investigate the ability of scalable literature based discovery (LBD) methods to identify side effects of pharmaceutical agents. The advantage of LBD methods is that they can explain the plausibility of a drug-adverse event association, thereby assisting human reviewers to validate the signal, which is an essential component of pharmacovigilance.

METHODS We drew upon two large repositories containing knowledge extracted from the biomedical literature by two natural language processing tools, MetaMap [4] and SemRep [5]. We evaluated two LBD methods that scale comfortably to the volume of knowledge available in these repositories. Specifically, we evaluated Reflective Random Indexing (RRI) [6], a model based on concept-level co-occurrence, and Predication-Based Semantic Indexing (PSI) [7], a model that encodes the nature of the relationship between concepts and thus enables reasoning over drug-side effect relationships to recover causal relationships. The patterns of relationships between concepts are referred to as "discovery patterns" [8]. An evaluation set was constructed from the Side Effect Resource 2 (SIDER2) [9], which contains known drug-adverse event relations, and models were evaluated for their ability to "rediscover" these relations.

RESULTS Our results (Table 1) demonstrate that both RRI (MAP is 0.0520) and PSI (MAP is 0.0848) can recover known drug-adverse event associations, and PSI performed better overall (AUROC is 0.6841). With discovery patterns, PSI has the additional advantage of being able to recover the literature underlying the reasoning pathways it used to make its predictions. Taking rosiglitazone and myocardial infarction as an example, the evidence supporting a causal relationship has been retrieved: *rosiglitazone* INTERACTS_WITH *apolipoproteins_b* [10,11] INTERACTS_WITH *ldl_cholesterol_lipoproteins* [12] ASSOCIATED_WITH myocardial_infarction [13], etc.

DISCUSSION In this research, an emerging, scalable method of LBD that uses distributional statistics to infer and apply discovery patterns was adapted to evaluate the plausibility of drug-adverse event relationships for pharmacovigilance. The effective application of large amounts of partially accurate biomedical knowledge to this problem was facilitated by the scalable and robust nature of approximate inference in geometric space. This approach was shown to be more effective than a comparable co-occurrence-based baseline, and has the further benefit of permitting the retrieval of evidence underlying the assertions used by the system to make its predictions. Consequently, our approach provides the means to assist with expert clinical review by providing evidence supporting the plausibility of the connection between drugs and ADRs. Furthermore, the models we have developed can be applied to filter drug-adverse event signals that are detected in spontaneous reporting systems or EHR data, a direction we plan to explore in future work.

Integration of Generic Electronic Health Records: Moving from Technology Acceptance to Adaptive Structuration to Reciprocal Coordination[1]

Susan A. Sherer, Chad D. Meyerhoefer, Shin-Yi Chou, Mary E. Deily (Lehigh University)
Michael Sheinberg, Donald Levick (Lehigh Valley Health Network)

Introduction: Incentives provided through the American Recovery and Reinvestment Act spurred the adoption of electronic health records [1], which are now being integrated between multiple care settings. Our study addresses the following questions: How do users appropriate vendor-supplied electronic health records? How do they achieve coordinated care through integration of ambulatory EHR systems with hospital information systems?

Methods: We used a longitudinal qualitative multiple case embedded design [2]. Our field site was the Lehigh Valley Health Network, which implemented generic electronic ambulatory records within four obstetric (OB/GYN) practices that varied in patient demographics as well as previous level of record automation. These records were then integrated with the system at Lehigh Valley Hospital's Labor and Delivery (L&D) unit, beginning with the triage unit that evaluates patients during pregnancy. Data were collected from archival sources including meeting notes and workflow documentation and 75 one-hour interviews with both medical care providers and administrative staff in multiple locations at three points in time: (1) initial implementation of records and flow of discrete data from office system to the hospital system; (2) after hospital summary data were integrated into office records, and; (3) one year after both discrete and summary data were flowing between office and hospital record systems. We transcribed and coded all data within NVIVO, beginning with open coding, and then moving to axial and selective coding, using two coders to insure reliability and consistency [3]. Conceptual categories that described themes related to value, reengineering, facilitators, and unexpected consequences were created from the evidence [4]. We used the situated change perspective [5] to understand organizational transformation by analyzing the adaptive structuration patterns [6, 7], work-arounds [8] and the impact on coordination capabilities [9] and unintended consequences [10]. We used an iterative approach to develop a grounded theory that focused on relationships among concepts with strong inter-rater reliability as well as significant differences among respondent demographics (e.g. job title, office location) and implementation time.

Results: Performance and effort expectancy [11] were critical initial factors in the acceptance and use of these records, and varied among participants with different roles. Specific facilitating conditions that influenced these factors were awareness and champions. As the data were integrated, there were structural adaptations, including time and field shifting of data entry and avoidance of and inefficient data retrieval that led to unexpected consequences for coordination. Sequential coordination required the establishment and management of organizational policies; for example, sign-off adherence policies, since sign-offs triggered record availability. Additionally, the use of integrated information was impacted by trust in the data source. For example, users did not typically rely on discrete lab data that flowed between systems; instead they generally resorted to searching for source lab results. As the information flowed in both directions, system and process changes were instituted to achieve reciprocal coordination. System changes occurred when there were imposed-deep misalignments [12]. For example, there were data recording differences between care settings focusing on episodic vs. lifetime care. Process changes were instituted among participants who became more proactive. Reciprocal coordination required new roles and processes that took time and recognition of the importance of standardization.

Discussion: The lack of trust in shared data between multiple systems suggests that integration efforts should support rapid retrieval of source data rather than data flow between multiple systems. New systems should be facilitated via a common platform or one that provides easy retrieval and access to source data. Differences in performance and effort expectancy among roles should be evaluated before adoption, and matched with appropriate facilitators. More successful adoption occurs when complementary process changes are instituted along with the system, rather than after the system is implemented, since structural adaptations can negatively impact coordination. Data entry adaptations can lead to problems with record coordination, which can require organizational oversight. While commercial record systems may be designed to record clinical results, they require improved data retrieval capabilities or complementary investments in new processes. Cultural differences between care settings must be considered when integrating these systems. While organizational policies can support sequential coordination, reciprocal coordination requires buy-in from users, as well as mechanisms to support trust in the data. Shared system usage can support individual and organizational adherence to standardization, but this can take years to achieve.

How Can We Partner with Electronic Health Record Vendors on the Complex Journey to Safer Health Care?

Dean F. Sittig, PhD[1], Joan S. Ash, PhD[2], Adam Wright, PhD[3], Dian Chase RN, MSN[2], Eric Gebhardt, MBI[2], Elise M. Russo, MPH[4], Colleen Tercek, BS[2], Vishnu Mohan, MD, MBI[2], Hardeep Singh, MD, MPH[4]

Introduction

On January 15, 2014, the Office of the National Coordinator for Health Information Technology (ONC)[1] released the SAFER (Safety Assurance Factors for EHR Resilience) guides[2]. Our multidisciplinary group developed these 9 guides, each consisting of 10-25 recommendations covering several key facets of both EHR infrastructure (e.g., system configuration, contingency planning for downtime, system-to-system interfaces) and high-risk clinical processes (e.g., computer-based provider order entry with clinical decision support, abnormal test result reporting, patient identification, and clinician-to-clinician communication). As part of the iterative guide development and testing process, we conducted over 100 interviews and over 100 hours of field observation at eight U.S. healthcare organizations (HCOs). Following release of the guides, the EHRA (Electronic Health Record Association) responded with a detailed critique of these guides, noting that many of the recommendations would require new or improved features, functions and usability[3]. We performed an analysis of our data in an attempt to identify how HCOs were currently working or could work together with their vendors to make the EHR safer and more effective. Our goal was to create a robust foundation of knowledge to foster a HCO-vendor partnership and outline specific roles and responsibilities of EHR vendors in order for them to fully contribute to implementing and maintaining safe and effective EHR-enabled healthcare systems.

Methods

This qualitative study used rapid assessment data collection and analysis processes[4]. We identified all vendor-related quotes from over 2000 pages of interview transcript data previously collected during the SAFER project[5] using keyword searches of vendor names of the systems used at all of the sites (e.g., Cerner, Epic, LMR) coupled with generic terms such as EMR, EHR, vendor, electronic record, and HIT. To perform a content analysis, we divided our research team into 3 groups to review sub-sets of the interview transcripts. Each group member independently reviewed all the transcripts their group was assigned and then the group members worked together to reach consensus on the key themes identified. Next, the groups discussed their findings with the entire multidisciplinary research team to further clarify and refine the themes identified until a set of standard codes was agreed upon. Finally, using this combined thematic coding scheme, each group went back and reviewed and recoded (as necessary) their data. The final results were then reviewed and approved by the entire team.

Results

Table 1 lists and defines the 8 themes the team identified during the content analysis. These themes, ranging from new technical specifications to improved support and training, illustrate the complexity of creating and maintaining safe and effective EHRs. In many instances, representatives of the HCOs expressed a need to work more closely with their EHR vendors to address limitations in functionality and usability of their existing EHRs.

Discussion

Our analysis suggests that while the EHR Developer Code of Conduct[6] is a good start, further improvements in safety are likely to occur only with close partnership with vendors on the eight thematic areas we identified in our work. Within these areas, defining specific roles and responsibilities for vendors could achieve a shared understanding of how to achieve safer and more effective EHR-enabled health care.

Table 1. Key themes that EHR vendors must address if we are to achieve the safe and effective EHR-enabled healthcare system that healthcare organizations want and patients deserve.

Theme	Definition
Technical Functionality of EHRs	Features and functions that EHR developers are responsible for creating, for example CPOE functionality, system-to-system interfaces, system configuration capability (customizability)
Usability	Features of the user interface that describe the "look and feel" as well as the functions available to users
EHR Standards	Requirements, specifications, guidelines or characteristics that are used to increase availability, confidentiality, and integrity of data collection, storage, transmission, and reporting
EHR Testing	Methods to help users and organizations understand whether the EHR and all of its components are working as designed, intended, and required to provide safe and effective care
Workflow Processes	Issues related to how the EHR supports the clinical workflow by facilitating data entry, review, communication, or monitoring
Personnel to Support EHR Implementation and Use	Human resources involved in the design, development, testing, implementation, and evaluation of all aspects of the EHR-enabled healthcare delivery system
EHR Infrastructure	Computers, networks, cables, power, air conditioning, etc. required to support the EHR application
Clinical Content	Information provided to clinicians to help them select the most appropriate tests or treatments and document their actions

Quantifying the Utility of Medical Tests using Longitudinal EHR Data

Stein Olav Skrøvseth, MSc, PhD[1,2], Knut Magne Augestad, MD, PhD[1,3], Shahram Ebadollahi, PhD[2]

[1]University Hospital of North Norway, Tromsø, Norway; [2]IBM Thomas J Watson Research Center, Yorktown Heights, NY; [3]University Hospitals Case Medical Center, Cleveland, OH

Introduction: Increased adoption of Electronic Health Records (EHR) has resulted in availability of sizeable longitudinal medical data. This data could potentially be leveraged to model disease progression among other things.[1] In this work we use such longitudinal EHR data to quantify the value of medical tests performed as part of the routine patient care. A test is any procedure performed to increase the knowledge about the state of a patient; both for diagnostic or screening purposes. The information content of a test can be quantified in a data-driven way using information theoretic measures, contrasted to the knowledge-driven basis often inherent in other approaches relying on the value of information.[2] We define the utility of a test to be a function of the information content of the test over the impact of that test, such as cost, risk or discomfort to the patient.

Methods: We model a patient trajectory using a set of parameters $\boldsymbol{\theta}$. Available to us is a set of tests $\boldsymbol{\xi}$, each of which gives a result $\boldsymbol{y}$ modeled by a random variable $\boldsymbol{Y}$. The purpose of any test regime is to increase our knowledge of the parameters in the model. In an information theoretic framework this is equivalent to reducing the entropy of the posterior distribution of the parameters. Using observational data we design a classification or regression machine such that the probability $\boldsymbol{\pi}(\boldsymbol{\theta}|\boldsymbol{y},\boldsymbol{\xi})$ of a parameter $\boldsymbol{\theta}$ for a given value $\boldsymbol{y}$ of a test $\boldsymbol{\xi}$ can be estimated. Then, the expected information content of a test in a particular phase is the expected reduction in entropy of that test,[3]

$$\boldsymbol{\Delta}(\boldsymbol{\xi}) = \boldsymbol{S}(\boldsymbol{\theta}) - \boldsymbol{E}_{\boldsymbol{Y}}[\boldsymbol{S}(\boldsymbol{\theta}|\boldsymbol{Y},\boldsymbol{\xi})].$$

To validate the concept, we extracted the full EHR from the gastrointestinal department at the University Hospital of North Norway through 2004-2012 and identified 990 patients who underwent surgery for colorectal cancer along with all blood samples taken in the course of the patient's hospitalization. The patient model is binary with $\boldsymbol{\theta}$ denoting second surgery within 30 days post index surgery. Specifically, we coupled the information content to second surgery for anastomosis leakage (AL), a very severe complication for these patients.[4] The patients' pathways were divided into time periods relative to the point of index surgery, and for all tests of any one kind taken during that period, the information gain was computed.

Results: The information gain for C-reactive Protein (CRP) in the different temporal phases is shown in Figure 1, left. Corresponding validations were done for other tests. The maximal information content for this test related to second surgery is on days 3-4 post surgery, while tests performed prior to 1 day post surgery contain close to zero information. Figure 1, right side, shows the likelihood $\boldsymbol{\pi}(\boldsymbol{\theta}|\boldsymbol{y})$ as function of $\boldsymbol{y}$ (denoted *Value*), relaying the reasonable conclusion that higher CRP is associated with higher probability of resurgery.

Discussion: Blood tests are a very cheap and common procedure carrying little to no negative impact. However, their commonplace usage means there is a large amount of data in any EHR on which to base the current approach. The methodology can easily be expanded to other tests, in particular different modalities of radiology that carry costs in terms of economy, discomfort and radiation risks. Additionally, the simple binary patient model used in the current work can be replaced with arbitrarily complex patient models by adjusting classifiers or regression machines accordingly. The main challenge with this approach is having sufficient data for training the classifier and estimating entropy. Also, we assume that that the system is stationary such that the entropy can be consistently estimated, which may not always be the case as healthcare is a constantly evolving enterprise. When using several tests as input there may be significant overlap in their information content which can be separated out using, e.g, independent component analysis (ICA) or similar techniques.

In our analysis, the information content of CRP related to second surgery was associated with higher values of CRP taken on day three after the index surgery. CRP is known to generally increase post surgery,[5] though the connection to utility as defined here has not been made. Our results correlate well with the real world clinical knowledge that there is a utility to CRP 3-4 days after surgery.[6] The information theoretic approach provides a data-driven way for quantifying the information content of tests. Test utility may play a major role when applied to test associated with high negative imapct for healthcare or the patient.

Identifying Metastases from Pathology Reports in Lung Cancer Patients

Ergin Soysal, MD, PhD[1], Jeremy L. Warner, MD, MS[2], Joshua C. Denny, MD, MS [2], Hua Xu, PhD[1]

[1]School of Biomedical Informatics, University of Texas Health Science Center at Houston, Houston, TX; [2]Dept. of Biomedical Informatics, Vanderbilt University, Nashville, TN

Introduction

Metastatic patterns at the time of cancer recurrence are one of the most important prognostic factors in estimation of clinical course and survival of the patient. However, this critical information is rarely recorded in a structured format in cancer registries. This paper describes a system for identifying metastases and their location from free text pathology reports, which offers an attractive solution to this unmet clinical research need.

Methods

We selected 540 pathology reports from 262 patients with lung cancer in the cancer registry who had no metastasis at the time of initial diagnosis and later returned to clinics with metastatic lesions at an unknown site. A physician reviewed each pathology report to identify metastatic lesions. Among those, a random group of 100 patients (217 reports) were separated for use as test subjects for evaluation. Recall and precision values were calculated by comparison of the system output against a physician review on the test subjects.

Diagnosis sections of pathology reports were modeled around the specimen entity (Figure 1) in relation to other named entity classes such as body location/structure, procedure, or histological type. Location information is further classified into metastasis sites such as liver, bone and lymph nodes. Corresponding SNOMED CT® (SCT) concepts were used to create concept subsets, based on "*is a*" relationships to these generic parent concepts – e.g., the histological type subset was formed by concepts that have "*is a*" relationship to |Malignant neoplasm| 367651003 or |Malignant neoplastic disease| 363346000. The system lexicon was prepared from the SCT concept descriptions with respect to these class hierarchies, recursively. For every lexeme, probabilities were calculated for each given class. The lexicon was further enriched by synonyms from UMLS® and variations using LVG and the SPECIALIST[1].

The pathology reports were processed with *sentence boundary detection*, *tokenization* and *section header identification* modules to identify the *diagnosis sections*. Then, *part of speech tagging*, and *chunker* modules generated the phrases (Figure 2). At this stage, phrases were reprocessed for the negation and tumor grade terms using a dictionary based lookup. The identified phrases were then assigned to a class based on naïve Bayesian probabilities calculated for the lexemes forming the phrase using the physician's gold standard. For a given phrase with n lexemes $l_1, \ldots l_n$, the probability of being a member of a class C is calculated as $p(C|l_1, \ldots l_n) = \prod_{i=1}^{n} p(C|l_i)$, where the probability of class C for a given lexeme l is $p(C|l) = (p(l|C) \times p(C))/(p(l))$.

As the final step, rule-based information extraction was performed to identify metastases and their sites with respect to the specimen entity and its relationships (Figure 2). The diagnosis section had certain patterns that can be modeled as finite number of entity flows. Therefore, each entity class was accepted as a state. This approach also provided an advantage for rule based handling of negations. At the end of each path, detected entities were linked to each other with proper relationships based on generic classes, and stored as instances.

Results

The system was tested on 217 reports from 100 patients, who had metastatic disease at an unknown site. Results were compared to physician extracted information. Recall and precision values for metastasis detection were 82.69% and 87.76% correspondingly. Metastasis site detection was found to have a recall of 89.62% and precision of 93.13%. Finally, detection of lymph node involvement had a recall of 83.87% and a precision of 86.67%.

Discussion

We have demonstrated that an NLP approach using naïve Bayes can identify the site of metastatic recurrence with high precision and recall. There are many potential applications for such a tool, like recoding "*unknown metastatic site*" records in existing tumor registry data. The tool could also be generalized to any pathology narrative text programs to provide "rapid learning systems" for cancer care, with a vision of providing clinical decision support based on data collected in near-real-time at a national scale[2].

Uncertainty and Information Seeking in a Diabetes Online Community

Si Sun, MS
School of Communication and Information, Rutgers University, New Brunswick, NJ.

Abstract
This study offers insights into the types of uncertainty that led diabetes patients to seek information in a large online community. A total of 1,440 threads in 2013 were analyzed, 453 of which reflected various types of uncertainty related to information seeking. Uncertainty was classified according to categories identified in existing literature. Among the four major types of uncertainty located in everyday settings, only two are observed in the online environment. This difference points to patients' possible concerns with and the personal difference that eliminates the necessity of online information seeking.

Background
The self-management nature of diabetes treatments combined with the complex and unpredictable symptom patterns make the experience of uncertainty an inevitable part of many aspects in patients' daily lives. This uncertainty, usually resulted from a gap in patients' knowledge could lead patients to seek and share information. Recently, these information seeking and sharing activities have increasingly carried out online. In fact, patients turn to the Internet for health information more often than they communicate with doctors. Many theories of uncertainty and their applications examine why people seek or not seek information as ways to solve a problem or cope with a disruptive event. However, little is known about how information seeking in online environment compares to that in offline settings as influenced by types of uncertainty.

Methods
The dataset used in this study includes 1440 threads from patients in the online community of Diabetic Connect, one of the largest diabetes social networking sites in the United States. The last response to these threads range from January 2013 to June 2013. Text analysis is conducted to identify the types of uncertainty patients mentioned in the thread starters, and the results are compared with Middleton's[1] categorization of uncertainty in type 2 diabetes. The uncertainty related to information seeking is identified with an indication of a cognitive gap, such as "I don't know" and "I'm totally lost", or an affective symptom[2], such as "Afraid", "overwhelmed", and "scared ". This cognitive gap or affective symptom usually follows with explicit or implicit support seeking. For example, a patient expressed need for new information "Newly diagnosed…what did you have for meals? Need some good ideas PLEASE"; another patient also noted her affective symptoms when soliciting help "I get so confused because I … keep getting told I will not feel low or have low BG when taking [medicine]. Anyone else feel lows when while taking [medicine]?" (The quotes above are slightly modified to assure patient privacy.)

Preliminary Results and Discussions
Of the 1440 threads analyzed, 453 thread starters include at least one expression that indicates uncertainty. Other threads that do not indicate uncertainty may (a) share health information collected by patients, (b) share personal experiences, (c) post Q&A on how to use website features of the online community, or (d) call for participation in community activities. The thread starters expressing some level of uncertainty encompass types of uncertainty also identified by Middleton, including (a) health-related uncertainty, such as complex and unpredictable symptoms patterns, diagnosis, treatment and regimen, and prediction and decision making; and (b) personal identity construction and maintenance. However, some types of uncertainty, including (c) social life related uncertainty, such as information sharing and perceived stigma, and (d) financial issues, are not observed in this sample.

This difference may be the result of patients' decision-making concerning whether to share information online for the purpose of information seeking, because topics such as stigma and financial issues are usually considered too sensitive for public discussions. Individual differences may also be a cause for this difference: (a) patients who perceived social stigma may avoid discussing about diabetes in public; (b) patients who interact with others online may have fewer issues with information sharing; and (c) patients who have access to the Internet may be less financially stressed. An interview study is necessary to determine which of the above speculations are true.

Implications
This investigation of the types of uncertainty prompting patients to seek information online versus those in everyday lives enables a rich understanding of the underlying reasons for patients to choose different channels when communicating about various health-related issues. This perspective could help information professionals and healthcare providers understand patients' information needs and the suitable channels for delivering support for these needs.

Phenome-wide Association Studies Using NLP-Derived Phenotypes

Pedro L. Teixeira MS[1]; Robert Carroll MS[1]; Lisa Bastarache[1]; Peter J. Speltz[1]; Joshua C. Smith, MS[1]; Joshua C. Denny, MD, MS[1,2]
Depts. of [1]Biomedical Informatics and [2]Medicine, Vanderbilt University, Nashville, TN

Introduction: Electronic health records (EHRs) are becoming a powerful tool for clinical and genetic research. In addition to standard phenotype-based genetic studies, EHR-linked biobanks enable phenome-wide association scans (PheWAS). Using PheWAS, one can rapidly search for associations between a genotype and many phenotypes – highlighting potential pleiotropy. Prior PheWAS leveraged ICD9 billing codes as the basis for phenotypes. However, much health information may only be found within narrative EHR text – at potentially increased granularity and accuracy. This work shows that PheWAS performed using NLP-derived phenotypes from problem lists (PL), discharge summaries (DS), and history and physical (H&P) notes, without per-phenotype refinement, can replicate and sometimes improve upon the original ICD9-based method.

Methods: Vanderbilt's BioVU, a DNA biobank, is linked to a de-identified form of the EHR known as the Synthetic Derivative. We used PL, DS, and H&P notes of the first 6,260 European-American individuals entered in BioVU. Each of these documents is typically typed as narrative text. Notes were mapped to SNOMED-CT concepts using the KnowledgeMap Concept Indexer (KMCI) and SecTag, which identifies section context for concepts. We ignored concepts that were negated, possible, and those predicted to be associated with individuals other than the patient (family or otherwise). In addition, we further refined this set to the following UMLS semantic types: findings, diseases or syndromes, therapeutic or preventive procedures, signs or symptoms, neoplastic processes, pathologic functions, and congenital abnormalities. Finally, the less structured format of DS and H&P notes led to a higher rate of false positives using KMCI. We improved performance by limiting results to unambiguous matches with KMCI and the following high value sections (and their subsections): history of present illness, past medical history, hospital course, and assessment and plan. We used concepts via two routes of differing granularity. The first treats each unique CUI as a phenotype, while the second aggregates similar CUIs into a single phenotype by mapping them to ICD9-based codes and then to the existing PheWAS hierarchy of phenotypes. The mapping was constructed from a combination of the ICD9-CM to SNOMED-CT maps available through the National Library of Medicine. Both the 1:1 and 1:many mappings were used to maximize concept coverage. PheWAS was then run using the R PheWAS package for the same five SNPs on the same population as in the original PheWAS demonstration paper. These SNPs are known to be associated with rheumatoid arthritis (RA), multiple sclerosis (MS), coronary artery disease (CAD), carotid atherosclerosis (CAS), Crohn's disease (CD), and atrial fibrillation (AF). All analyses include age and gender as covariates and used logistic regression assuming an additive genetic model. Phenotypes were only considered if there was a minimum of 20 cases.

Results: Of the individuals examined 6,232 had at least one note type, 6,145 had PL, 4,026 had DS, and 5,536 had H&P. Table *1* presents the resulting p-values and odds ratios for the five SNPs across the various NLP-based methods in comparison to the original PheWAS paper or relevant GWAS results. NLP-methods have shown similar performance or better across all five SNPs. Substantial improvements in p-value were seen for both AF and RA with both granular concepts and ICD9-aggregated PheWAS concepts. Additionally, the NLP-methods demonstrated associations with concepts more granular than seen with ICD9 aggregation. One such concept was "relapsing remitting multiple sclerosis" with rs3135388 at a p-value of 8.04E-08 and an odds ratio of 5.59 in addition to its association with "generalized multiple sclerosis" at a p-value of 1.63E-04 and odds ratio of 1.75. The former is well above a Bonferroni-corrected threshold of significance of 1.90E-05. Of note, not all NLP sources performed similarly. Fewer cases are detected for NLP-based methods with discharge summaries performing particularly poorly across all diseases except AF.

Discussion: We have shown that NLP-based PheWAS can replicate associations seen with both traditional GWAS and the original ICD9-based PheWAS method. There is improvement for some diseases but issues with acronym disambiguation introduced NLP errors in some documents, especially shorter documents (such as PL) hindering accurate context-based word-sense disambiguation. In addition, the coverage changes depending on document type and condition. For example, typically chronic and less granular concepts are documented in PL. NLP-based methods will likely benefit from further increasing the number of document types included given appropriate filtering of less reliable unstructured text within the EHR.

Table 1. Comparison of NLP-Based PheWAS to Original ICD9-Based Method. The table shows a comparison of cases detected, OR, and p-values across the five SNPs examined with the various forms of NLP-based PheWAS: CUIs mapped to ICD9-based PheWAS codes or fully granular CUIs from a variety of sources. The last uses a more stringent minimum of 2 CUI occurrences to define a case.

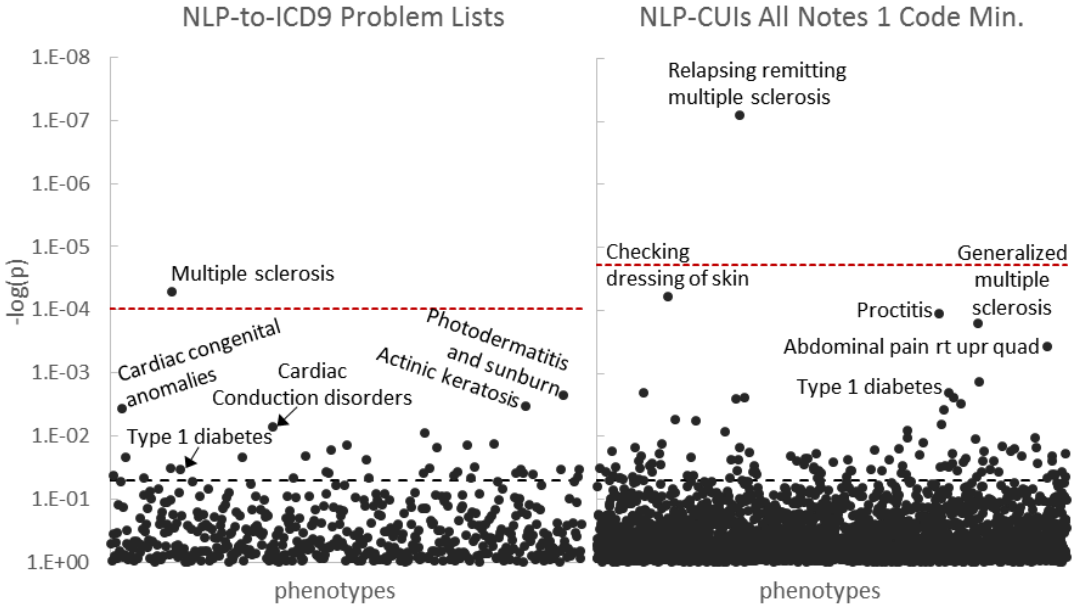
Figure 1. Manhattan Plot of NLP Collapsed to ICD9 Codes and Granular CUI-Based Phenotypes (rs3135388). Phenotypes with some of the most significant p-values are labeled for NLP-derived concepts mapped to ICD9-based phenotype codes (problem lists) and granular NLP-based concepts - cases have a minimum of one code (all notes). The most significant for each is MS (5.17E-05) and relapsing remitting MS (8.04E-08) respectively.



Integrated Data Management System for Medical Registries: A Case Study using RexDB®

Charles Tirrell[a], Frank J. Farach[a], Meredith Yourd[a], Owen McGettrick[a], Oleksiy Golovko[a], Leon Rozenblit[a]
[a] Prometheus Research LLC, New Haven, CT

Summary: Disease- and procedure-specific registries are powerful tools for the improvement of long-term patient care. Unfortunately, registries are typically too expensive for smaller practices and organizations to develop and maintain. We describe an affordable and scalable alternative: an open source solution that can integrate institutional (EHR) and primary research data.

Introduction and Background: Medical registries are growing both in importance and value with rapid increases in (a) the amount of data on each patient and procedure, (b) the value of tracking outcomes, and (c) the desirability of sharing information between health professionals. Registries enable researchers to track individual patient and outcomes and evaluate cohort-level statistics that guide the improvement of patient care. Prominent examples of recent registry systems include the Intelligent Research in Sight (IRIS) Registry™ [1] and the National Cardiovascular Data Registry® (NCDR) [2]. Two difficulties prevent wider adoption of registries. First, registry applications are expensive to develop, and, where levels of change are high, even more expensive to maintain. Second, the heterogeneity and complexity of source data, especially from electronic health record (EHR) systems, makes it expensive to transform and integrate data using traditional methods. We set out to develop an approach that addresses both difficulties by using an existing open-source stack specifically designed to support heterogeneous research data under conditions of rapid protocol change.

Methods: We developed an integrated registry data management system based on the Research EXchange DataBase (RexDB), an open source (AGPLv3) stack initially developed to help for the acquisition, curation, exploration and sharing of human biomedical and behavioral research data. RexDB allows analysts (without help from programmers) to configure custom data structures, extract-transform-load (ETL) processes, and front-end application screens and workflows. ETL processes utilize HTSQL, an analyst-friendly, open source query language, which allows users to navigate, explore and manage, complex datasets with a simple query syntax. This approach allows analysts who are close to the data and to the end-users to configure auditable data transformations, in contrast to typical approaches using SQL or a programming language that relies on extensive and expensive communication between user, analyst, and programmer. In addition, the RexDB platform employs layers of functionality to support the secure management of ePHI data, as well as being developed using highly secure and industry tested open source packages that ensure the security at all levels of the application.

Results: Our initial implementation delivered two procedure-specific registries: interventional and diagnostic. Each of these registries accepted data from external EHRs, filtered the results, and transformed the data to integrate properly with a normalized, transactional data structure. A configuration mechanism allowed users of the system to configure new registries, including additional forms for data entry and visit-types with required procedures. Finally, an integrated data exploration tool allowed users to generate custom datasets based on registry participation, disease conditions and item-level data values from form data entry. Users could generate analyst-configured and ad hoc custom reports based on these datasets and share them with external researchers. Importantly, each registry took approximately three days to configure, including setting up the initial ETL processes from a single EHR system; each custom EDC form took approximately an hour per page; and each report took approximately an hour per logical condition. User-experience reports on the system will be available by the time of the meeting.

Discussion: Our initial findings suggest that the RexDB design philosophy of empowering the analyst can address both major difficulties blocking registry adoption. We have found that the level of configurability presented to analysts in RexDB is novel compared to other software platforms, where there are significant limitations placed on the ability to create custom data models, workflows, ETL processes, and screens. Additionally, the configuration format and tools that drive this customization has been shown to have a short learning curve with semi-technical individuals, which leads to a much shorter development time for deploying user-focused system customizations. We plan to apply this technology stack to additional registries for a wider perspective. Surprisingly, adapting the core RexDB study management suite to meet the needs of registry management and reporting required only a slight modification of a previously developed “research study management” model. To understand this further, we plan to explore the relationship between clinical registry and research data models in the future. This case study also suggests that using an open-source stack has the benefit of aligning incentives between the technology services vendor and the registry customer: Because the vendor cannot use intellectual property to lock in a customer, they are continually motivated to deliver high levels of service.

Maintenance of a Standard Pharmacy Terminology within a Controlled Medical Vocabulary Server

Michael Totzke, Jon Herbert RN, R. Dean Woolstenhulme MS, LAc
3M Health Information Systems, Murray, Utah

Introduction: The 3M Healthcare Data Dictionary (HDD) functions as a master reference terminology, which integrates and supplements multiple other standard vocabularies.[i] By mapping concepts to a central terminology, a terminology server like the HDD allows translation of data between standard terminologies, between legacy, or site-specific terminologies, and between standard and legacy terminologies. One of the several drug terminologies that the HDD incorporates is RxNorm. RxNorm is a standardized drug nomenclature developed and maintained by the National Library of Medicine (NLM) designed to help translate among multiple other standard drug terminologies. With the selection of RxNorm as the drug terminology standard required to meet Meaningful Use criteria, it has become necessary for the HDD to maintain RxNorm's drug data from a more longitudinal perspective. Our former process for maintaining RxNorm dealt solely with mapping of the current version, without regard to managing changes over time.

Methods: The concept identifier in the HDD is the Numeric Concept IDentifier (NCID) and we map the RxNorm RXCUI to our code based on concept meaning. The NCID denotes a unique concept in the HDD. The RXCUI denotes a unique concept in RxNorm, whereas the STR is the human readable description, and the RXAUI is the description numeric identifier. When an RxNorm concept is mapped to the equivalent HDD concept, the RXCUI/RXAUI/STR triplet is loaded as descriptions on the NCID. There were three basic steps at the beginning this project. To begin with, we needed to ensure that the current RxNorm triplets mapped in the HDD were in a state to be compared with the native RxNorm triplets (from the source terminology). We had to remove old RxNorm data that we hadn't maintained, and so we inactivated any RXAUI or STR value that was not associated with an active RXCUI on an NCID. This is because, of the three types of values, the RXCUI was the only code that we had been tracking on a monthly basis. Next, there were active RXCUIs mapped to NCIDs that didn't have an RXAUI and STR, or had only one or the other, that needed to be added to the HDD. Once we had triplets on every NCID where an active RXCUI was mapped, we could make our comparison. Our approach to this was to create a series of queries, as database views, in our ORACLE database, that would do all the comparison work of the two sources of data, RxNorm and the HDD.

Results: There were various types of outcomes in which the comparisons passed or failed. The first type of failure was a complete triplet missing from the HDD. The second type of failure to match was when there was an active RXCUI mapped to an NCID, but the RXAUI and the STR were inactive in the RxNorm source table. This occurs when the STR, or term, for the RxNorm concept was altered which means that the RXAUI also changes, but the RXCUI was conceptually the same. This type of change most often was the result of some type of cosmetic change, such as capitalization of a word. But there were also many of this type which resulted in a change of concept meaning. One example of this is RXCUI 80163, which changed from *Alanine 2.07 MG/ML* to *Alanine 20.7 MG/ML.* The next two types of failure were the result of either the RXAUI *or* the STR being changed, and the other not changing

Discussion: Mapping maintenance of a standard pharmacy terminology is extremely important to data quality. The impetus for changing our RxNorm mapping process came from several places, the most important of which was the need to improve the quality and consistency of the mapping. We realized that simply adding new RXCUIs when they were new, or simply removing RXCUIs when they were inactivated in RxNorm, perpetuated potentially serious data problems. Through this new process, we were able to find errors and inconsistencies in our own data, including identifying duplicate concepts (e.g. RXCUI 1309219 *poppyseed oil* and RXCUI 1432299 *poppy seed oil*), and errors in RxNorm data as well.

Semantic Role Labeling for Modeling Surgical Procedures in Operative Notes

Yan Wang, MS[1], Serguei Pakhomov, PhD[1, 2], James O. Ryan, MS[4], Genevieve B. Melton, MD, MA[1, 3]

[1]Institute for Health Informatics, [2]College of Pharmacy,[3] Department of Surgery, University of Minnesota, Minneapolis, MN; [4]Department of Computer Science, University of California Santa Cruz, Santa Cruz, CA

Introduction

The application of NLP systems to process clinical text continues to attract researchers who aim to extract valuable information from large numbers of clinical notes and to automatically provide necessary information to users in a timely and scalable fashion. In analyzing operative notes, linguistic features including the presence of extensive predication often with action verbs were previously found to be key to utilizing these notes[1]. We previously created PropBank style PAS frames for a set of top action verbs from operative notes[2], which were used as to as a framework for operative note SRL. In this study, we adapted and customized a SRL system for modeling surgical procedures in operative notes. Our adapted SRL system will be used in downstream tasks such as modeling of procedure phases, summarizing and presentation to provide important surgery information in a succinct and easily comprehensible fashion for clinicians.

Method

A Maximum Entropy (ME)[3]-based SRL model was trained on an annotated corpus collected randomly from 3,000 Laparoscopic Cholecystectomy and 6,481 notes from six other gastrointestinal surgical procedures for 20 top surgical action verbs. The Predicate Argument Structure (PAS) of the action verb in each sentence was annotated using the surgical PAS frames created previously[2]. A combination of additional features were use to augment the performance of the system, as follows. Extra syntactic phrases were also collected from syntactic output produced by MetaMap[4] for detecting noun phrases in biomedical text by using SPECIALIST minimal commitment parser[5]. The ME SRL model was trained using the Unified Medical Language System (UMLS) semantic types[6] of the head word as a new feature based on a set of heuristic rules for semantics type groupings. Finally, an adapted unlexicalized PCFG syntactic parser was used to obtain better syntactic parse trees for operative notes, which provides necessary syntactic information for SRL model training.

Result

Our SRL system along with two existing SRL systems (ASSERT[7]- a constituency-based SRL system trained on Wall Streat Journal corpus and - ClearNLP[8] - a dependency-based SRL system trained on a PropBank annotated clinical corpus including MiPACQ[9]) were evaluated. ASSERT had the lowest performance with a precision of 63%, recall of 54%, and F-measure of 58%. In comparison, ClearNLP had better performance with a precision of 69%, recall of 59%, and F-measure of 64%. Our ME SRL system trained on operative notes showed improved performance with a precision of 69%, recall of 82% and F-measure 74%. This was consistent with microaveraging and macroaveraging analyses, along with analysis by semantic role type (Tables 1 and 2). Table 2 shows the SRL system performance on different semantic role types such as Arg0 - a core argument usually specifies the agent of an action, ArgM-CAU - which indicates the reason of an action and ArgM-DIR – a semantic role shows the path of the motion. As shown in table 2, the SRL system performs very well on detecting core arguments of surgical actions, which contain the most important details about surgical actions.

Discussion

Our study demonstrates that a ME SRL system trained on annotated operative notes has improved performance over existing SRL tools. The corpus specifically annotated with domain PAS used in this study provided a robust training set for the ME engine to derive accurate model parameters. Future work will include scalable automatic acquisition of PAS frames for more predicates to obtain wider coverage of most surgical actions and to extend PAS frames to include nominal action predicates.

Introduction: The process of finding accurate phenotypes (e.g., congestive heart failure) from heavy volumes of imperfect practice-based electronic health record (EHR) data is a crucial enabling step for clinical and genetic research using EHRs. Billing codes often have been used in traditional phenotyping since most patients with the disease should be assigned a relevant code for the billing purpose. However, due to their inaccuracy or incompleteness, using billing codes alone may result in low specificity or sensitivity. Work from collaborative phenotyping groups such as the Electronic Medical Records and Genomics (eMERGE) Network suggest that a combination of diagnosis codes with other EHR components, e.g. medication and clinical notes, shows an improved performance on multiple disease phenotypes. In this study, we tested a logical hypothesis that algorithmic combinations data from multiple components of EHR may improve the accuracy, and possibly recall. We evaluate the phenotyping performance of three major components of EHR – billing codes, keywords in clinical notes, and specific medications -- on a broad spectrum of pre-selected diseases.

Methods: This evaluation was conducted by using de-identified EHR data at Vanderbilt. ICD9 codes were retrieved from administrative claims data and aggregated with phenome-wide association codes (PheWAS) codes. We defined primary notes as problem lists, discharge summaries, or history and physical notes (H&P). Keyword searches and simple rules were performed on primary notes to determinate if a patient has a positive mention of the disease. The list of specific medications was obtained through MEDI, is a freely-available, computable medication-indication resource. Medication data in our EHRs are often embedded in clinical narratives and were obtained through employing MedEx in addition to electronic prescribing data. Ten diseases were selected for this evaluation study: atrial fibrillation (AFIB), Alzheimer's disease, breast cancer, gout, and human immunodeficiency virus (HIV) infection, multiple sclerosis (MS), Parkinson's disease, rheumatoid arthritis (RA), type 1 diabetes (T1D), and type 2 diabetes (T2D). For each disease, subjects were classified into one of the seven categories based on the evidence presented in their EHRs, i.e. 1. ICD only, 2. primary notes (PN) only, 3. medications only, 4. ICD and PN, 5. ICD and medications, 6. PN and medications, and 7. ICD, PN, and medications. A group of 25 patients per disease category (a total number of 175 patients for each disease, 1750 patients for the ten diseases) were randomly selected for physician chart review. Review results were used to estimate precision, recall, and F-score of each component. Kappa scores between reviewers were between 0.68-0.90.

Results: The precisions for single components alone were inconsistent and inadequate for accurately phenotyping (0.06-0.71). Limiting to patients with ≥2 diagnosis codes improved the average precision to 0.84. We observed a more stable and higher accuracy when using ≥2 components (mean±standard deviation: 0.91±0.08). Primary notes offered the best recall (0.77). The recall of diagnosis codes was 0.67. Again, two or more components provided a reasonably high and stable recall (0.59±0.16). Overall, the best performance (F score: 0.70±0.12) was achieved by using ≥2 components. Although the overall performance of using diagnosis codes (0.67±0.14) was only a slightly lower than using ≥2 components, its precision (0.71±0.13) is substantially worse than using ≥2 components (0.91±0.08).

Discussion and Conclusion: Our results show that use of multiple modalities of EHR data derived from available computable resources improved upon use of a single resource for precision and F-score. Using multiple ICD9 codes substantially improved ICD code precision to 0.84±0.12. Medications alone were not sufficient to diagnose disease, even for highly specific meds such as HIV drugs. We suggest that multiple EHR components should be considered for future phenotyping efforts. These methods may extend to many other diseases. More work is needed to eliminate false positives for some diseases, especially in PN.

Table 1. Precisions for various categories based on chart review results. The "only" categories refer to that category without other mentions; e.g., "ICD only" refers to patients with ICD codes without a Med or PN mention; "ICD" refers to patients with any ICD (they may also have Med or a PN mention. PN=Primary Notes; SD=Standard Deviation

CONSIDERATIONS of DUAL PROCESS THEORIES for EHR DESIGN

Charlene Weir, PhD[1,3] Bryan Gibson, PhD[1], Alan Morris, MD[3], Jorie Butler,PhD[2], PhD,[1] Matt Samore[1] and Jonathan Nebeker, MD[1,3]

[1]IDEAS Center of Innovation, SLC VA, [2] GRECC, SLC VA [3]Dept. of Biomedical Informatics, University of Utah,

Introduction

In order to maximize the promise of EHRs, increasing attention is being focused on the redesign of the electronic health record.(1-3) One major goal is to enhance the cognitive support of clinicians and workflow in order to improve the quality of care, enhance safety, and expand the usefulness of the EHR.

Dual Process theories.(4, 5) posit two memory systems: 1) a network of associations that function through spreading activation to support rapid pattern-matching (System 1); and 2) a slow, rule-based, conscious system that functions through active reasoning (System 2). Both systems are continuous and simultaneous processes with humans generally motivated to preserve cognitive resources by avoiding System 2 processing, unless necessary.(4, 6, 7) Our goal is to expand the discussion of EHR design by reviewing the empirical psychological literature to incorporate a dual process a "matching hypothesis" for the design of decision support. We propose that maximizing rapid automatic processing is only the first step and that the next two priorities are to support higher levels of reasoning and the self-regulation of attention. Each issue is discussed below.

Support for Adaptive Control of Information Environment. As noted above, System 1 and System 2 processing occurs simultaneously and continuously. Managing attention resources in relation to the uncertainty of the information space in order to reach the epistemological goals of accuracy and speed is complex when there are multiple clinical priorities. Literature on adaptive control will be reviewed.(8)

Rich Contextual Displays. Expert decision-making uses pattern-matching mechanisms characteristics of the powerful associative memory system. However, if the information-space is impoverished or displays too rigid, clinicians engage in active search processes, which take substantial effort. Literature related to "feeling of knowing" integrated displays, and situational mental models will be presented.(9, 10)

Goal-based processing. Human information processing is contextual, goal-based, and linked to action. Simulation tools are one aspect of goal-based processing that is neglected in EHR design, despite the importance of simulation in human thought. Literature on simulation will be presented and linked to issues of clinical decision-making.(11-13)

Planning and Action (Decision-Making). Care planning software should support both planning and action. Research in decision-making have identified that information is handled differently at different times in the decision-making sequence. Literature on action support will be reviewed.(14, 15)

Support for Establishing Common Ground Across the Team. Common ground refers to the shared understanding between co-workers regarding their knowledge of the goals, intentions and responsibilities of each other. Many clinical work-arounds are instantiations of processes to establish common ground (16). Literature related to dual process impacts on establishing common ground will be reviewed in order to show how to improve clinical coordination.(17)

A Framework for Analyzing Inpatient Nursing Costs

John M. Welton, PhD, RN[1]
[1]University of Colorado College of Nursing, Aurora, CO

Introduction

Traditional methods of measuring nursing time (intensity) and costs do not address patient level nursing care. Most hospital cost accounting procedures use department or cost center averages known as nursing hours and nursing costs per patient day (NHPPD, NCPPD). This method is problematic for several reasons, first, there is no way to allocate nursing time or costs to individual patients. Second, the use of NHPPD/NCPPD do not measure individual variances in nursing care for patients within a medical diagnosis or Diagnosis Related Group (DRG). Essentially all patients are allocated the same "average" nursing care for each day of stay within the cost center. Because hospitals are reimbursed based on these diagnoses, there is no link between how nursing resources are expended for different patients, their related costs, the billing for inpatient care and payment to the hospital. Third, there is a compelling need to better identify cost drivers within the healthcare system and registered nurses make up over 25% of hospital expenditures[1]. Lastly, there is an emergent need to devise new methods to extract nursing related data from existing electronic health records (EHR) and combine these data with other operational, clinical, financial, and quality data systems to dovetail with other emerging operational informatics techniques and develop nursing business intelligence and analytic tools.

Methods

The University of Colorado College of Nursing formed a consortium of hospitals and healthcare systems in 2013 named the Colorado Collaborative for Nursing Research (CCNR). This brings together nurses and other clinicians and leaders from various healthcare settings to devise methods to share data to address common problems. One primary deliverable is to devise a framework to identify nursing direct care time and costs and allocate these to each individual patient to overcome the issues identified above. The value of this work is the ability to link several key measures of nursing care to each individual patient: the actual hours of care provided; the cost of that care using either a standard cost or the actual wage of the nurse and aides; the overall assignment of nurses to patients, and the distribution of the assignment to the scheduled nursing staff and aides for a particular shift.[2]

The cost model is based on original work conducted by the Yale team that developed the DRG to separate nursing costs into a nursing cost center based on patient level nursing intensity,[3] however this feature of the DRG was never implemented. More recent work by Kaplan and Porter out of the Harvard School of Business present a framework for patient level costing models in healthcare.[4] We draw from these collective work to guide the development of a patient level nurse costing model.

In two pilot studies conducted at separate intuitions, data were extracted from several existing EHR components: 1. The Clairvia (Cerner Corp) nurse staffing and scheduling software; 2. Existing human resources data to identify nurse characteristics and wages; 3. Discharge summaries to identify patient characteristics and diagnoses; and 4. Admission/Discharge/Transfer (ADT) information. Using Thompson's approach, the ability to identify the actual hours of care is based on the assignment of each nurse to a patient from which a cost using actual or standard wage can be applied. This method is more robust and explains a higher portion of variance of actual nursing care hours delivered that other methods such as nurse to patient ratios.[2]

Results

The key nurse and patient specific variables are detailed in Table 1. A few key metrics derived from these data are shown in Table 2 and include both nursing time and cost as well as other useful metrics about nurses and the care they deliver to patients. These new data derived from the nursing assignments can provide a rich analytic environment as well as near real-time data about internal operations and nursing resource management. In one of the pilot studies, nursing costs per patient day were found to vary between \$132 - \$1,455.[5] In the second pilot, 20% of the patients consumed 50.4% of all nursing hours and costs.[6] Also, for adult patients on the medical/surgical floors, nursing hours and costs per day declined by hospital length of stay from 6.7/\$334 for 1 day of stay, 5.2/\$260 for 7 days, 4.9/\$\$244 at 14 days, and 4.8/\$242 at 21 days.

Further development of both the data collection methods as well as analytics is anticipated. This includes adding nursing quality and performance metrics. For example, future models will be able to measure the demand for nursing

care and the actual care (time and costs) delivered using nursing terminologies in the Nursing Outcomes Classification tool mapped to nursing assessment data.[7] Metrics will identify varying patterns of care, for example more care than is needed is inefficient and extra time and costs can be calculated to aid resource decision making to provide the most efficient level of staffing based on patient needs rather than nurse to patient ratios. Also, nursing care time and costs will be benchmarked across different care settings aligned with key outcome goals such as length of stay and quality measures tied to value-based purchasing.

Table 1. Core Data from Nursing Data Extraction

Entity	Label	Comment
Nurse Characteristics	StaffID (PK); Role (RN, LPN, Aide); Unit experience; Wage; Hospital experience; Nursing experience; Assigned unit; Work category (FT/PT, per diem, traveler);	Main table for nurse characteristics
Patient Characteristics	PatientID (PK) Age, Sex, MSDRG, Hospital length of stay,	Main table for patient characteristics
Nurse-Patient Assignment	StaffID; PatientID; UnitID; Shift ID; Patient acuity; Demand nursing hours required; Nursing hours delivered; Nursing costs	Association table for nurse:patient assignment Nursing costs = time * wage

Note, a full list of all variables can be found at: http://links.lww.com/JONA/A303

Table 2. Nursing Care Metrics and Analytics

Patient Level	Unit Level	Hospital Level
• Direct nursing care hours and costs per day and per case. • Nursing acuity level (demand for nursing care) • Sum of nursing direct care time and costs per case • Mean experience level of provided nursing care.	• Mean assignment (# patients per nurse); direct care hours and costs all nurses and aides • Mean nursing experience level and sum and percent of hours by nursing degree (e.g. BSN) • Sum and percent of hours and costs for float or per diem.	• Mean direct nursing care time and costs per DRG/Diagnosis • Mean nursing hours and costs by day of stay. • Nursing time and cost variability over time and comparison of demand vs. actual care hours delivered

Conclusion

A method to extract nursing direct care time and costs from the nurse to patient assignment is proposed. Initial pilot study results confirm both the suitability of these methods to measure patient level nursing time and costs and extract data from existing EHRs. This method is vendor agnostic and can provide a more robust data environment to examine nursing care at the individual nurse-patient level of analysis. Further discussion is needed to identify ways to widely disseminate and test this model in a variety of patient care settings to identify and benchmark nursing care.

Exploring Bayesian Network Development Using Unsupervised Machine Learning for Patient Risk Assessment

Bruce Wilson, MBA[1], Christine Tsien Silvers, MD, PhD[1,2], Cindy Crump, MA[1], Loretta Schlachta-Fairchild, RN, PhD, FACHE[3], COL Jeffrey S. Ashley, AN, PhD[4]
[1]AFrame Digital, Inc., Reston, VA; [2]Children's Hospital Informatics Program, Boston, MA; [3]iTelehealth, Inc., Cocoa Beach, FL; [4]Center for Nursing Science and Clinical Inquiry, Walter Reed National Military Medical Center, Bethesda, MD

Introduction. Unsupervised machine learning methods were used to explore predictive Bayesian networks[1] in a research program to develop a mobile real-time patient risk management tool. Scoring systems or models to predict mortality have been described but typically only use data from the first 24 hours in an intensive care unit (ICU).[2-4] This work explores ICU outcome prediction using data from both the first 24 hours and beyond, as a stepping stone toward ultimately predicting need for early intervention in those with chronic diseases, which accounted for 84% of all health care spending in 2006 and cost $315.4 billion for just heart disease and stroke in 2010.[5]

Methods. Time-series data for 29 patient measurements—including physiological vital sign, laboratory values, demographic data, work history, and outcomes—were retrospectively collected for each patient in an IRB-approved protocol. Patients had been admitted for burn, infection, hypovolemia, and traumatic brain injury during a five-year period ending in October 2007. Bayesian networks were developed using a constraint-based unsupervised machine learning development package (FasterAnalytics, DecisionQ Corp.). Prior to training networks, the time-series data were pre-processed by (1) removal of invalid values, (2) transformation of each patient time series into a single unified dataset, and (3) definition of temporal "observation windows." Cross-validation and area under the receiver operating characteristic (ROC) curve (AUC) analyses were used to identify which set of time windows and data transforms produced the most predictive model. Bayesian networks were validated using a leave-one-out cross-validation methodology. Each test set's predictions were then used to calculate an ROC curve by feature of interest.

Results. Data were collected from 650 patients throughout their ICU stays. Models using hospital admission data alone showed that all patients appeared to have an equal chance for a positive outcome; models developed from chosen time frames prior to the known outcome, however, showed that electronically-collectible patient parameters, such as glucose, respiratory rate, and blood pressure, can be used to differentiate risk and estimate patient outcomes. Cross-validation analysis yielded a mean AUC of 80.4% for predicting outcome in this preliminary work.

Discussion: The initial results are promising; however, the modeling work has identified some limitations and additional requirements. First, the current models required substantial optimization in order to arrive at the best results. Additional research will involve testing additional reference time windows, data transforms especially temporal abstractions, model pruning techniques, and further experimentation with feature selection. Identification of decision thresholds that take prevalence into account and optimization of predictive values should also be explored. Second, clinical validation is necessary through review of clinical practice, along with a prospective, randomized, controlled clinical trial of the best candidate prediction models. While the study datasets are from an ICU, Bayesian network models have the potential to shed light on which easy-to-collect measurements might be highly correlated to identifying changing patient risk stratification using lightweight mobile monitoring tools.

Evaluating Living Situation, Occupation, and Hobby/Activity Information in the Electronic Health Record

Tamara J. Winden, MBA[1,5], Elizabeth S. Chen, PhD[3,4], Elizabeth Lindemann[1], Yan Wang, MS[1], Elizabeth W. Carter, MS[3], Genevieve B. Melton, MD, MA[1,2]

Introduction: Social and individual behavioral factors play an important role in diagnosis, prevention, health outcomes, and quality of life[1,2]. As defined by the World Health Organization, "social determinants of health are the conditions in which people are born, grow, live, work and age"[3]. Living situation information, such as residence type, with whom the patient lives, housing density, physical living conditions, and social support, all have been shown to have significant impact on a patient's health outcomes[4,5]. In addition, occupation and hobbies/activities can adversely impact health[6,7]. Within electronic health record (EHR) systems, social determinant documentation may be entered as structured data or unstructured text (e.g., in clinical notes or free-text data entry fields). Building upon previous work[8], the goal of this study was to evaluate the documentation of living situation, occupation, and hobbies through analysis of specific ancillary notes as well as other structured and unstructured sections of the EHR.

Methods: Progress and consult notes from a publicly accessible data source, MTSamples.com (MTS), and the University of Pittsburgh Medical Center (UPMC) NLP Repository were annotated to extract general social history sections and sentences. Each sentence was then annotated using an annotation schema developed specifically for living situation, occupation, and hobbies/activities (Table 1). These "training" data served to validate the annotation schema, which was then used to annotate inpatient social work notes from the Epic® Systems Corporation EHR in 2013 at Fairview Health Systems (FHS) which included patients who consented to have their medical records used for research. Specifically, 100 social work inpatient notes were randomly extracted from the EHR and annotated to classify living situation, occupation, and hobbies/activities information. Lastly, the EHR was queried for structured occupation information documented within the social history module for all inpatients for 2013.

Results: A total of 691 progress and consult notes were evaluated from MTS (n=491) and UPMC (n=200). A total of 558 social history annotations were then further classified, by consensus of two reviewers, into 10 topic areas covering living situation, occupation, and hobbies/activities as well as related exposures. This analysis identified 546 unique sentences related to the topic areas. Of the total notes evaluated 10.4% had at least one sentence related to residence, 20.2% had references to living density or cohabitation, and approximately 24% had sentences related to occupation (Table 2). Evaluation of the 100 social worker notes showed 40.0% had at least one sentence related to residence, 39.0% had social support, and 34.0% had living density. Lastly, the structured field for occupation from the FHS EHR was found to be populated in only 0.03% of inpatients in 2013.

Discussion: Our evaluation of the MTS and UPMC progress notes demonstrates that the topic areas of living situation, occupation, and hobby/activities are being documented in the EHR with occupation-related sentences found in 24% and living density in 20.2% of notes. Exposure-related sentences are found much less frequently. The social work notes showed higher levels of documentation especially related to Social Support. Evaluation of additional notes and note types including physical and occupational therapy as well as other structured, semi-structured, and unstructured sections of the chart is in progress.

Conclusion: Social determinants are important considerations in the provision of care and are also becoming more important as in terms of population health management. The contributions of this work represent a first step towards further informing biomedical standards for the representation of social determinants in the EHR, as well as the design of clinical documentation tools.

Table 1: Annotation Schema for Living Situation, Occupation, and Hobbies/Activities

Topic	*Definition (Example Sentence)*
Residence	Dwelling types, physical residence. (*"The patient lives at a skilled nursing facility."*)
Living Conditions	Sanitation, safety. (*"The patient was living in a home which was reported to us to be without any heat or light and a good deal of excrement and urine in the building.")*
Living Density	With whom the patient lives. (*"The patient lives with her daughter.")*
Social Support	Assistance in support of care or activities of daily living. (*"The patient lives with her family being helped by the family and friends.")*
Living Situation Exposure	Exposures related to living situation. (*"He lives in a home where there are smokers."*)
Animals	Presence of animals in residence, domesticated animals as well as livestock. (*"At this time, there is also exposure to indoor cats and dogs."*)
Occupation	A regular activity performed for payment, career, profession, vocation, employment, or non-paid vocations such as full-time student, stay-at-home mom, retired, unemployed. (*"He was an IT software developer, but he has been out of work."*)
Occupation Exposure	Exposures related to occupation. (*"This is a 91-year-old male with a previous history of working in the coalmine and significant exposure to silica…"*)
Hobby / Activity	A hobby or activity, paid or non-paid, engaged in as a means of passing time; an avocation. (*"Hobbies: Computers, hiking, camping, fishing."*)
Hobby / Activity Exposure	Exposures related to hobbies or activities. (*"He likes to refinish old furniture so he works extensively with lead paint."*)

Table 2: Percent of total notes and number of sentences. [Percent of total unique notes (# individual sentences)]

	MTS	*UPMC*	*TOTAL "Training"*	*FHS*
Residence	6.3% (35)	20.5% (48)	10.4% (83)	40.0% (54)
Living Conditions	0% (0)	1.5% (6)	0.4% (6)	0% (0)

Automated Identification of Unsuspected Lung Nodule Findings in Radiology Reports with Natural Language Processing and Text Classification

Ryan Wise MSc, Jonathan Duckart MS, Jianji Yang PhD
Portland VA Medical Center, Portland, Oregon, USA

Abstract

Detection of lung nodules on radiology images is the critical first step in timely follow-up and cancer diagnosis. Detection is hindered by the difficulty of identifying findings buried in radiology reports. An automated text classification algorithm is developed to detect these cases. The algorithm achieves a 94% recall in recognizing lung nodules. Future work is needed to integrate the algorithm into the workflow of the care coordinator for patient follow-up.

Introduction

Lung nodules on radiographic images are important indicators for potential malignancies and can lead to early detection and treatment of lung cancer. The Portland VA Medical Center (PVAMC) implemented an Unsuspected Radiologic Findings (URFs) Pathway in 1996 to ensure the timely communication, evaluation and diagnosis of lung nodules[1]. In 2013, a web-based lung-nodule-tracking registry was implemented to facilitate population-level management of URFs. In order to expand the URF program to facilities where no URF diagnostic code is used, an automated algorithm is needed to identify URF cases from free-text reports. In addition, an algorithm can further improve PVAMC's detection of URFs by identifying cases with missing URF codes.

Past work on automated identification of lung nodules in radiology reports include keyword-based[2,3] and rule-based[4] natural language processing (NLP) systems. In this work, however, we addressed the problem using text classification with machine learning algorithms[5,6]. The machine-learning approach allows greater flexibility in training the system over time to be sensitive to inter-facility differences in report and dictation styles, helping the system to achieve a degree of portability not possible in hard-coded rules and keywords.

Methods

The URFs Pathway program at the PVAMC has created an annotated corpus of reports, consisting of image studies where any part of the chest can be seen. Roughly 5% of those are coded to reflect a positive URF. We used this corpus and the Scikit-learn module[7] to build a bag-of-words model to classify image reports as either positively or negatively indicating URFs. Optimizing recall of positive URF findings was our criterion for model selection.

Benchmarking to identify the best algorithms. A random selection of 10,000 cases from the corpus were used to train and test 11 different classifiers, and the results were compared to choose models for further tuning.

Final Model. The linear-kernel support vector machine (SVM) was selected for further optimization. The development and testing process pipeline are depicted in Figure 1. The development phase used 10,000 cases divided into 6,500 for 3-fold cross validation and 3,500 for testing. Preprocessing steps included regular-expression matching to collapse related concepts into single features in order to achieve greater statistical efficiency (Table 1). For example, measurements in the text notes, such as "3.5mm by 2.01mm" or "sub-1mm," would each be replaced by the single "MEASURE" feature. Two feature-selection models (a linear SVM with L1 penalty and a chi-squared feature selector) were used to obtain the most discriminative features for the classifiers. An inverted class-rate sampling technique was used to balance the two classes. The grid search program in Scikit-learn[7] was used to choose the regularization parameter that optimized recall. Finally, an SVM with an L2 penalty was trained and evaluated using a different set of 50,000 cases, with 32,500 used in training and 17,500 in testing.

Results

Table 2 shows the top six performers from the 11 benchmarking algorithms. The SVM with L1 penalty had the highest recall and F1 scores for URF-Positive cases. The performance for the final model is presented in Table 3. There was a 15% improvement in URF-Positive recall from the base model, accompanied by a drop in precision.

Discussion

While the performance of the final model is promising, further improvement on the model can be made in several areas, such as including relevant patient information into the feature set, e.g. smoking status, age, and gender. In addition, a user-feedback mechanism can be built into the registry to allow care coordinator to flag the false-positive results for routine model retraining and improvement. The trade-off made in focusing on higher recall at the expense of precision means that the care coordinator will need to review more false positives at first, but by improving the model using user feedback, a better precision could be achieved. Finally, exporting the model to other facilities with no codes for URF will require further evaluation of performance, and the model may need to be retrained and retuned after further user feedback. In conclusion, this automated text classification algorithm could be used to augment the current URF process at PVAMC and start URF monitoring processes at other facilities.

Acknowledgements
The authors would like to thank Drs. Aaron Cohen and Steve Bedrick for the valuable suggestions and comments to help improve the performance of the classifiers. The authors would also like to thank Judy McConnachie for her input and support.

Figure 1. Processing pipeline.

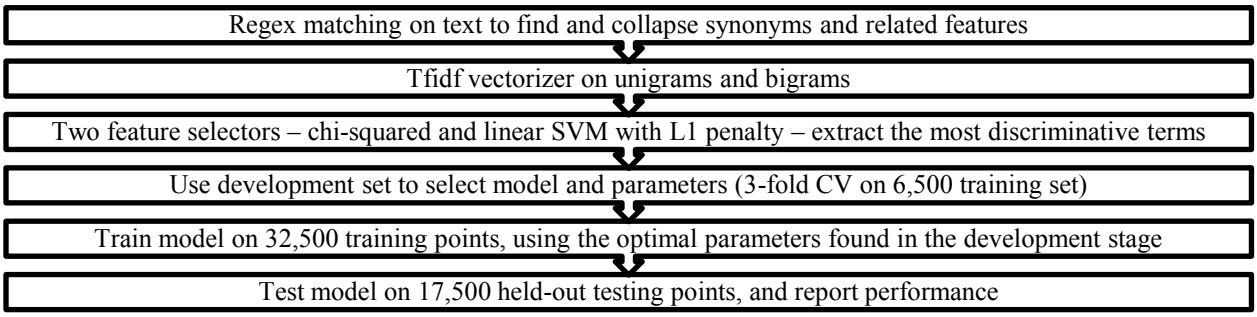

Table 1. Examples of term variations that were collapsed to related concepts.

Collapsed Concept	Regular Expression (examples)
MEASURE	(2.4mm, 2 by 5.5cm, 1.0 x 2.4cm, sub-1mm)
NODULE	nodul\w*("nodule," "nodular," etc.)
DATE	[0-9]+?[-/][0-9]+?[-/][0-9]+
LUNG	(lobe, lung, pleural, lingular, pulmonary, word beginning with pneumo-, etc.)
CANCER	(?:cancer|carcin|metastat)\w*

Table 2. Benchmarking algorithms. Table only displays the top six performing classifier results. Linear SVM with L1 penalty is the best performer on recall of URF-positive cases (underlined). SGD: Stochastic Gradient Descent, SVM: Linear Support Vector Classification.

Classifiers	L1-penalty SVC	L1-penalty SGD	L2-penalty SVC	L2-penalty SGD	Elastic-net penalty SGD	Naïve Bayes
URF-Positive Recall	**0.82**	0.79	0.78	0.78	0.78	0.77
URF-Positive precision	0.97	0.99	0.97	0.97	0.99	0.97
URF-Positive F1-score	0.89	0.88	0.87	0.87	0.87	0.86

Table 3. Performance of our tuned linear SVM with L2 penalty and regularization parameter C=0.9. Recall is the target for optimization. The final model reached a recall of 0.94 (underlined), with precision at 0.54. Performance of model on classifying both URF positive and negative cases, and the weighted average is reported.

	Precision	Recall	F1-score	Support
URF-Positive	0.54	**0.94**	0.69	772
URF-Negative	1.00	0.96	0.98	16,728
Weighted Average	0.98	0.96	0.97	17,500

Understanding Local Drivers of Health Outcomes: The North Carolina Community Health Information Portal

Charlene A. Wong, MPH[1], Deb Aldridge, MSN, RN-BC[2]
Annette Dubard, MD, MPH[1], Chase Haddix, MHA[1]

[1]Community Care of North Carolina, Raleigh, NC;
[2]Community Care of Southern Piedmont, Concord, NC

Background

Healthcare providers, public health workers, and community planners increasingly recognize the need to combine, analyze, and display health information in ways that promote understanding of clinical, social, and economic determinants of health. Geographic information system applications have proven to be highly impactful in targeting ways to improve health outcomes.

Methods

With federal funding from the Office of National Coordinator Beacon Award, Community Care of North Carolina, Southern Piedmont Beacon Community, NC Institute for Public Health, American Academy of Family Physicians' Robert Graham Center, and HealthLandscapes, Inc. collaborated to design a web-based geospatial visualization tool that integrates several public and clinical health indicators sourced from numerous databases including the US Census Bureau, Centers for Disease Control and Prevention, NC State Center for Health Statistics, Centers for Medicare and Medicaid Services Chronic Condition Warehouse.

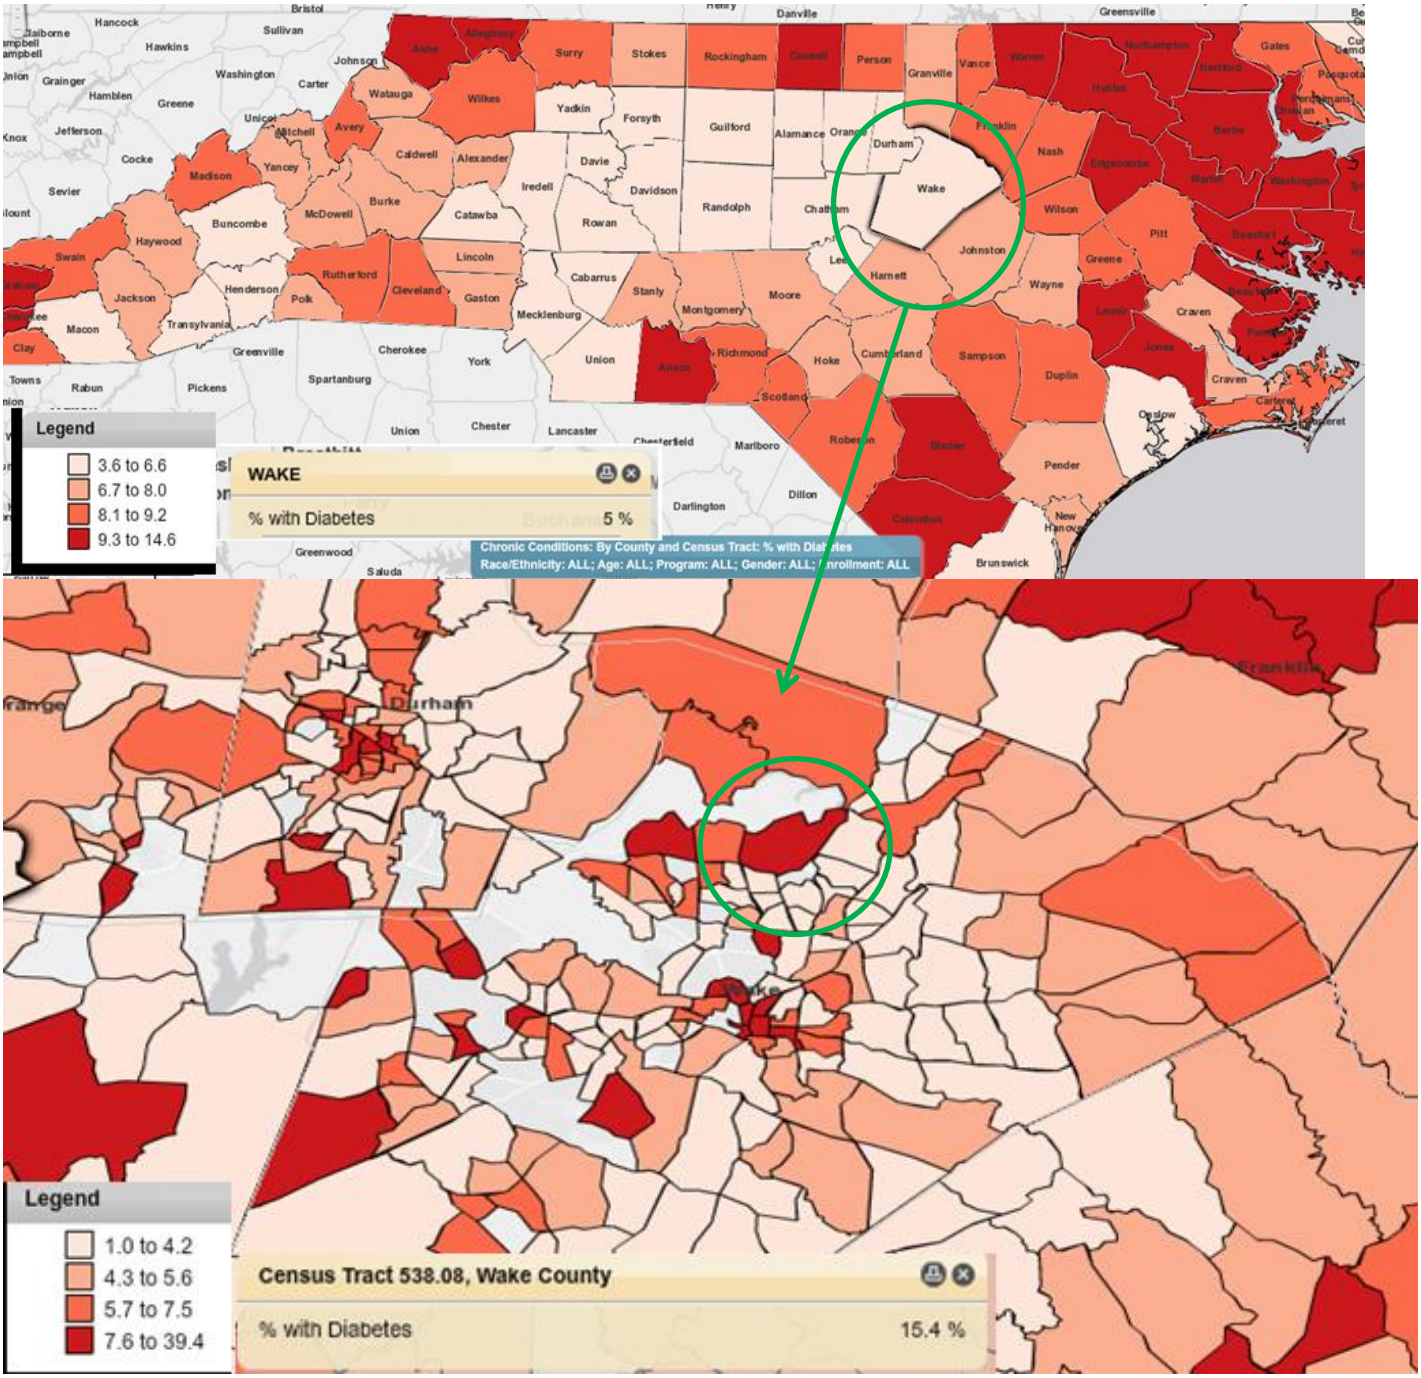
Results

The North Carolina Community Health Information Portal (NC-HIP, https://nchip.n3cn.org/) contains over 230 public and clinical health indicators including Medicaid and Medicare demographics, disease prevalence, cost, utilization and quality indicators; and general population indicators of socioeconomic and public health status. NC-HIP can geographically display disease burden at the health referral region, county, or census-tract level within North Carolina (Figure 1). Additionally, users can upload their own health data and compare their data with pre-loaded health indicators. Unique to NC-HIP, users can filter select Medicaid indicators based on gender, age, and race/ethnicity to examine health disparities at the local level.

Conclusion

NC-HIP equips healthcare providers, public health workers, policy-makers and other stakeholders with extensive health-related information to effectively respond to community needs through innovative data visualization. By revealing correlations between disease, social determinants, and access to care, NC-HIP serves as a resource for compiling a Community Health Needs Assessment (CHNA), guides optimal allocation of healthcare resources, and catalyzes targeted quality improvement activities at the local level.

Figure 1. Diabetes prevalence among Medicaid beneficiaries seen at the county level (top image) and at the census-tract level (bottom image, census tracts displayed for Wake County, NC only). Darker colors indicate greater diabetes prevalence. (Data source: Medicaid Paid Claims)



Identifying Clinical Decision Support Failures using Change-point Detection

Introduction: Evidence suggests that CDS can improve health care quality, safety, and effectiveness (1). However, unintended consequences and safety issues around CDS have also been reported (2). In prior qualitative studies, we identified several cases where CDS systems failed, in many cases without being noticed. Some of these failures led to patient harm. We sought to develop a method for detecting CDS failures.

Methods: Change-point detection is a simple form of anomaly detection aimed at identifying changes in sequential and time series data. We used five years of data on alert firing from Brigham and Women's Hospital (BWH)'s outpatient electronic medical record system. We built Poisson change-point detectors for each alert separately. Change-point detectors assume that data is generated by a consistent process and then look for points where it is likely that the generating process underwent a change in expected rate (3).

Results: Figure 1 shows the firing rates for four alerts from BWH. The blue bars show anomalies detected using change-point analysis. Of the anomalies, one was previously known to both clinical leadership and the EHR development team, one was known to the EHR team only, and two were previously unknown. We investigated each of these four anomalies, and found:

1. System-wide spike in alerts: Panel 1 shows a representative alert for chlamydia screening which reveals a large spike in the total number of alerts in a two-day period on June 15 and 16, 2009. The same spike is seen in all alerts at BWH. We found that a bug was introduced after a software update, causing incorrect and repeated alerts to appear – sometimes dozens per patient. The EHR team received several support calls and, after two days, resolved the bug by reverting to an earlier version of the code. Although the EHR team resolved the bug, they did not alert users or clinical leadership about the issue after resolution.
2. Lead screenings for 2 year-olds: At BWH, clinicians are alerted to screen children for lead at ages 1, 2, 3 and 4. Panel 2 shows the firing rate for the lead screening alert for 2 year olds. We found a large anomaly from 2009 to 2011, where the alert slowed abruptly, stopped and then abruptly resumed. Interviews with clinical, risk management and technical staff revealed that no one was aware of the issue before we identified it. Manually maintained change logs show no edits to the alert since 2006, and the root cause has not been identified.
3. Amiodarone/thyroid stimulating hormone (TSH) testing: BWH uses an alert to remind clinicians to monitor TSH in patients receiving amiodarone. In November, 2010 BWH changed the internal code for amiodarone, but only for new orders. The logic of the rule was not updated when the code was changed, so the alert continued to fire for patients already on amiodarone, but not patients newly started on the drug and the rule started slowly failing in November, 2010, represented by the slow decline in the graph. In February, 2013, we discovered the error coincidentally during a demonstration of the system and reported it to the Partners knowledge management team, who fixed it immediately, leading to the step-change in firing rate.
4. Aspirin and coronary artery disease: This alert suggests starting aspirin in patients with coronary artery disease who were not already receiving antiplatelet therapy. Upon investigation, it appears that this spike was due to a malfunction in the drug classification service, which caused the alert to fire for patients with CAD, even if they were already taking aspirin. The problem resolved when the classification services were fixed in response to a non-alert-related issue. No BWH staff were aware of the issue previously.

Discussion CDS malfunctions represent a real threat to patient safety. These relatively simple change-point detection algorithms we developed identified four actual CDS anomalies, only one of which was previously known. In future work, we plan to expand our system to include more sophisticated models for anomaly detection, to run it on additional types of CDS and to design and develop a real-time dashboard for detecting anomalies before they lead to widespread patient harm.

Figure 1: Firing rate of four alerts at BWH over a five-year period (weekend days in black, weekdays in blue) with anomalies indicated (horizontal blue bars show detected anomalies, green bar shows known anomaly).

Layered Spaces for Clinical Information Retrieval

Stephen Wu, PhD, Dingcheng Li, PhD, James Masanz, MS, Hongfang Liu, PhD
Mayo Clinic, Rochester, MN

Introduction

In clinical natural language processing (NLP), significant attenion has been directed toward and information extraction (IE) techniques; systems such as cTAKES[1] typically require some tailoring to specific use cases. In contrast, clinical information retrieval (IR) techniques intentionally generalize across use cases – in the form of queries. We hypothesize that clinical IR techniques can benefit by the inclusion of existing NLP techniques. To test this hypothesis, we introduce several NLP-based "layers" for IR in a language modeling framework, evaluating on a cohort identification task as introduced by the TREC Medical Records Track[2].

Methods

Our retrieval models use a language modeling approach, which embodies the intuition that a user will imagine a document that he/she wants, then write a query to match it. After preprocessing as in Figure 1, we include the following layers via interpolation (with example queries):

- Text: A standard Query Likelihood model[3]. For example, "patients who have a carotid endarterectomy".
- Concepts: UMLS CUIs produced in cTAKES. For example, "C0014099 C0014098 C0014098" where cTAKES yields both unique CUIs on "carotid endarterectomy", plus the latter one on "endarterectomy".
- Dependencies: Dependency parse nodes and arcs produced in cTAKES. For example, the dependency arcs "have↷endarterectomy carotid↶endarterectomy".
- Topics: Inferred from an LDA model with 800 topics.

Documents were retrieved from the TREC-med data set[2].

Results

Table 1 shows retrieval performance in MAP (mean average precision) from the inclusion of various layers. It is clear that the basic Text layer is the most useful of all tested layers, followed by Concepts, Dependencies, and Topics. The concept space yields the largest gain in performance over a baseline model, as it appears to complement the Text space well. Surprisingly, Topics (latent semantics), Dependencies (dependency arcs), and an overall combined model do not yield significant improvements on performance. It is important to note that the implementation details and data representation have a significant effect on system performance. We optimized for the Dirichlet smoothing parameter, but not for the number of LDA topics, the dependency parse representation, or linear interpolation coefficients.

Discussion

Our results imply that alternative representations of documents, no matter how linguistically sound or medically salient, have yet to completely replace text search. State-of-the-art language modeling systems[4] achieve excellent performance without the use of other layers (MAP=0.412). While work on alternative layers has shown promise[5, 6], they are rarely as optimized as the text layer, and further work needs to be done to capture their full potential.

Mining electronic health record data to detect drug-repurposing signals for cancers

Hua Xu Ph.D.[1], Qingxia Chen, Ph.D.[2], Jeremy Warner M.D., M.S. [3,4], Xue Han, M.S.[2], Min Jiang M.S.[1], Anushi Shah, M.S.[4], Melinda C. Aldrich, M.P.H., Ph.D. [5,6], Qi Dai, M.D.[6], Joshua C. Denny M.D., M.S. [3,4]

[1]School of Biomedical Informatics, The University of Texas Health Science Center at Houston, Houston, TX; [2]Department of Biostatistics, [3]Department of Medicine, [4]Department of Biomedical Informatics, [5]Department of Thoracic Surgery, [6]Division of Epidemiology, School of Medicine, Vanderbilt University, Nashville, TN, USA;

Introduction: Rapid growth in the implementation of large electronic health records (EHRs) has led to an unprecedented expansion in the availability of longitudinal datasets for epidemiologic and genomic research.[1] An exciting, but largely unexplored application of EHRs is to use them for drug repurposing studies, which seek new indications for existing drugs.[2] For example, recent evidence suggests metformin, a first-line therapy for type 2 diabetes, improves cancer survival improves cancer survival [3,4] and decreases cancer risk [5,6] versus other glucose-lowering therapies, indicating its clinical promise as a cancer therapeutic and an antineoplastic agent. We hypothesize that potential new indications of existing drugs, if real, can be quickly detected using EHRs, with the help of informatics tools and methods.

Methods: We linked a de-identified version of the Vanderbilt Tumor Registry to the Synthetic Derivative (SD) database, a de-identified copy of Vanderbilt's EHR. We identified a cancer cohort (excluding non-melanoma skin cancer) of 65,869 individuals. We limited drugs that were associated with more than 5,000 subjects in the SD, resulting in 301 generic drug ingredients. We further removed over-the-counter drugs, antineoplastics, and drugs used in supportive care of cancer patients, resulting in 226 drugs. For each drug, we identified cancer subjects who were exposed vs. unexposed to the drug using MedEx, a medication information extraction system for clinical text. Other covariates and outcomes included patient demographics (age, sex, race), tumor information (e.g., tumor type and stage), and time from cancer diagnosis to death or last medical record date (censored). To adjust for co-morbidity, we also included ICD 9 codes (mapped to disease groups) associated with each patient. We then examined each drug for its association with cancer mortality using Cox proportional hazards models controlling for the above covariates. We ranked all 226 drugs based on the size of the hazard ratio (HR) from Cox models. For the top 20 ranked drugs associated with reduced mortality, we manually searched Google or PubMed for prior evidence of the association.

Results: A total of 43,310 individuals were exposed to the 226 drugs included in this analysis. Table 1 shows the top 20 drugs that were predicted to be associated with improved cancer survival in this study. We found strong associations for a number of statins, angiotensin receptor blockers (but not angiotensin converting enzyme inhibitors), beta-blockers, and a few other medications. Metformin was ranked 18th. Among these 20 drugs, we found supporting evidence for 13 drugs. Some evidence was strong, e.g., the National Surgical Adjuvant Breast and Bowel Project is conducting a phase 3 study of rosuvastatin (ranked 1st in our study) versus placebo in patients with surgically removed stage I or II colorectal cancer to determine whether recurrence can be prevented. Much of the evidence is relatively weak. For example, sildenafil, ranked 7th in our list, is associated with a publication suggesting that it enhances the sensitivity of cancers to standard chemotherapeutic drugs.[7] If we further filter the drug list by p-value, thirteen of them have a statistically significant p-value ($<2.2x10^{-4}$, using Bonferroni correction for multiple comparisons with type-I error rate of 0.05). Among them, nine drugs have strong or weak evidence from literature, showing they could be related to cancer survival.

Conclusion: By linking a tumor registry to a large EHR database, we conducted a large scale screening of 226 drugs for their potentials for cancer therapy. Using the Cox model, we ranked drugs according to their potential to reduce mortality. Manual review showed supporting evidence in the literature for some top-ranked drugs, indicating the application of EHRs for drug repositioning. More data is needed to validate these associations for potential clinical use. With broader application of informatics methods in EHR data extraction and analysis, we envision rapid generation of large datasets for drug repurposing discovery and validation.

Table 1. Top 20 drugs that were associated with improved cancer survival, as predicted by this study. Drugs were ranked based on Hazard Ratio. Insignificant p-values ($<2.2x10^{-4}$) were highlighted in grey.

Rank	Drug Name	Literature Evidence	Hazard Ratio (HR)	HR 95% CI		P-value
1	rosuvastatin	Yes – strong	0.6014	0.5158	0.7013	8.66E-11

Operationalizing patient-generated health data: Home blood pressure monitoring as an example

Shipeng Yu, PhD[1], J. Marc Overhage, MD, PhD[1], Paul Tang, MD[2]
[1] Siemens Health Services, Malvern, PA [2]Palo Alto Medical Foundation, Palo Alto, CA

Introduction

Patient-generated health data (PGHD) are health-related data that are created, recorded, gathered, or inferred by from patients or their designees to help address a health concern. It is widely believed that engaging patients to play a more active role in their health and to collect PGHD can lead to better outcomes and more efficient care, but in order to achieve those benefits we need to better understand the workflows that will allow health care providers' electronically accepting and incorporating patient-generated health information into their clinical workflows. Home blood pressure monitoring is a good example of PGHD: the data are high volume, frequent and use in practice is not well understood and for which automation may play an important assistive role.[1] The objective of the current study is to explore the effectiveness of some automated trending algorithms on HBPM data, and to retrospectively compare with the intervention logs from clinicians acting as dedicated care managers who monitored these patients without the automated tool in order to shed some light on future research of operationalizing PGHD and seamlessly integrating PGHD and data generated through clinical encounters.

Methods

We used data drawn from EMPOWER-H, a trial of patient centric care management of hypertension, for this study. The 142 patients participating in this study were to record their BP measurements twice daily and share them with care managers who reviewed that data and used their clinical judgment to intervene with patients and their PCPs. The time frame for this study was from March 2012 to January 2013. We explored three trending algorithms to fit the HBP data from each patient in the study period, separately for systolic BP (SBP) and diastolic BP (DBP): the *Moving Average* method computes the mean BP measurements over the past 14 days at every time point; the *Polynomial Fit* method conducts a 5-degree polynomial fit to the BP measurement data; and the *Gaussian Process Fit* method does a customized, non-parametric functional fitting to the BP measurement data. We then designed an automated alerting system where an alert was generated if either SBP or DBP 14-day moving average is above a predefined threshold (135 for SBP and 85 for DBP) for 14 continuous days. Once an alert was generated, the algorithm waited for 14 days to be activated again for further alert generation. We then compared the alerting algorithms with care managers' interventions that involved a medication change or suggested clinic visit or consultation. For each alert that was generated, we looked at whether there was an intervention within 7 days before or after the alerting date. We can then compute the accuracy of the alerting system treating the clinician's interventions as the gold standard.

Results

The 14-day moving average method generated 477 alerts in total, about 3.5 alerts per patient for the 10 month period. 56 patients (39%) did not have any alert, and 86 patients (61%) had at least one alert, out of which 19 patients (13%) had more than 10 alerts. Out of the 477 alerts, 113 (24%) had an intervention within 7 days before the alert, 88 (19%) had an intervention within 7 days after the alert, and 168 (35%) had an intervention within 7 days before or after the alert. Out of the 86 patients that had at least one alert, 28 (33%) had no intervention in the 7-day radius of any alert, 26 (30%) had interventions for at least 50% of the alerts, and 2 (2%) had interventions for 100% of the alerts (Figure 1).

Discussion

The initial results revealed that the algorithm did not generate any alerts for about 40% of the patients suggesting that their hypertension was under control. The concordance between the alerts generated by our algorithm and the patient states that triggered timely medical intervention was limited (around 35%). A careful review of all alerts for a selected subset of 10 patients indicated that often times the clinician elected not to make any changes in medical treatment at the time because the clinicians were aware of other considerations (e.g., patient preference not to change medications, desire to try lifestyle modification, patient undergoing stressful circumstances). We would expect to generate better alerts if the algorithm incorporated knowledge of these factors.

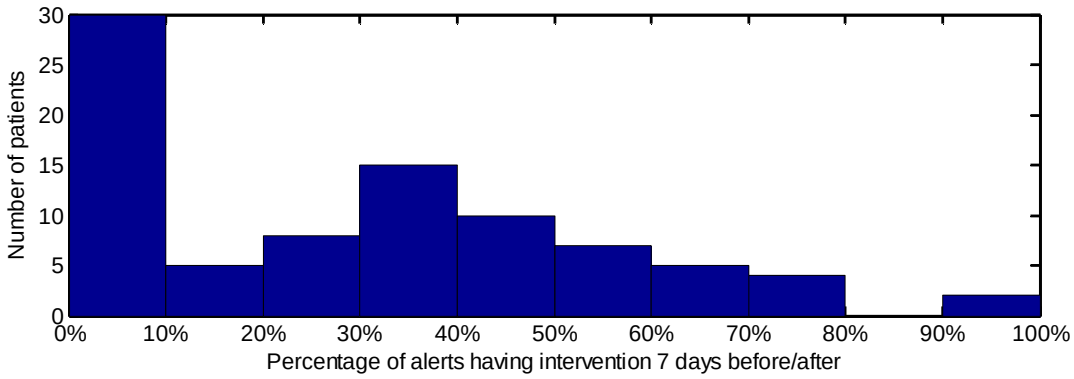

Figure 1 -- Clinicians did not intervene at all for 28 patients in whom the algorithm generated alerts and for two patients clinicians had intervened in all cases in which the algorithm generated an alert. Overall, alerts corresponded to clinician's interventions in about a third of cases.

Domain Adaptation for Semantic Role Labeling of Clinical Text

Yaoyun Zhang, Ph.D., Buzhou Tang, Ph.D., Min Jiang, MS, Jingqi Wang, MS, Yonghui Wu Ph.D., Hua Xu Ph.D.
School of Biomedical Informatics, The University of Texas Health Science Center at Houston, Houston, TX, USA

Introduction

Semantic role labeling (SRL), which extracts a shallow semantic relation representation from different surface textual forms of free text sentences (e.g., in "*liver biopsy*", "*liver*" is the source of the "*biopsy*" event), is important for understanding natural language.[1] While SRL approaches and corpora in open English domains are plentiful, few SRL studies have been conducted in the medical domain. This is probably due to the lack of annotated clinical SRL corpora, which are time-consuming and costly to build in the medical domain. Our study investigates domain adaptation techniques for clinical SRL. We want to leverage SRL resources from newswire and biomedical literature to improve performance and decrease annotation cost for clinical SRL. To the best of our knowledge, this is the first work introducing domain adaptation algorithms to address the task of clinical SRL.

Methods

Datasets: The PropBank corpus generated using newswire of financial domain and the BioProp corpus from biomedical literature specific to proteins were the source domain datasets. MiPACQ,[2] a clinical corpus with manually annotated SRL information, was the target domain dataset. **Algorithms:** Three state-of-the-art domain adaptation algorithms were employed: (1) transfer self-training (TransferSelf), utilizing top n-source domain instances with highest similarity to the target domain for enrichment of the target training set;[3] (2) instance pruning (InstancePrune), merging the source domain dataset with the target training set after removing the top n-most different instances from the target domain;[4] (3) feature augmentation (FeatureAug), amplifying target training features with weight-adapted source domain features.[5] **Evaluation:** The SRL performance using different domain adaptation algorithms with state-of-the-art open domain SRL features[6,7] was evaluated using 10-fold cross validation on the MiPACQ corpus by precision, recall and F-measure. The performance of the two subtasks argument identification (AI) and classification (AC), together with the combined task is reported. Three baselines; using the source domain only, target domain alone and direct merging the source and target domain datasets for training were produced and compared. To assess the effect of sample size, we also generated learning curves (plots between training sample size and F-measure) for different methods.

Results

As displayed in Table 1, domain adaptation using both the outside resources, PropBank and BioProp improved the SRL performance on MiPACQ. The FeatureAug algorithm with PropBank as the source domain dataset achieved a statistically significant higher F-measure as compared to the baseline using MiPACQ dataset only (F-measures of 82.83% & 81.53% respectively), indicating that domain adaptation algorithms could improve SRL performance for clinical text. Use of the FeatureAug algorithm leveraging the PropBank corpus with MiPACQ required lower amounts of the dataset for training (<50%) to perform at a comparable level as the baseline of MiPACQ alone (90%) (Figure 1). This demonstrates that annotation cost of clinical SRL can be reduced significantly by leveraging existing SRL resources from other domains.

Discussion

In this study, we address SRL of clinical narratives as a domain adaptation problem. We used two existing SRL corpora outside of the clinical domain and evaluated three state-of-the-art domain adaptation algorithms for the task of SRL of clinical text. Our results showed that domain adaptation strategies not only improved the performance of SRL on clinical text but also reduced annotation costs.

Further, different domain adaptation algorithms may be effective for different source domain datasets. FeatureAug achieved the best performance on PropBank, while InstancePrune achieved the best performance on BioProp. PropBank is assumed to be more diverse from the clinical domain as compared to BioProp. PropBank also has a larger dataset than MiPACQ (~9:1), thus increasing contribution of more useful features as well as noise distinct from the features of MiPACQ. As illustrated in Figure 2, increased sample size of PropBank decreased SRL performance without domain adaptation. Nonetheless, the feature weighting mechanism of FeatureAug facilitated the choice of effective features from PropBank, demonstrating a larger tolerance for domain gap. The data size of BioProp is smaller than MiPACQ (~1:6.4), with a lower feature distribution when merged with MiPACQ. InstancePrune achieved better performance by removing dissimilar instances along with potentially noisy features from BioProp.

Introduction The fundamental basis for EHR driven phenotyping is to represent a query or algorithm, such that it may be executed against a repository of clinical data. Hence, the overarching goal of this project is to formally evaluate existing phenotype algorithm representation models, identify gaps, and where applicable, propose and implement extensions. To achieve this objective, we evaluated the National Quality Forum (NQF) Quality Data Model (QDM)[1] and HL7 Health Quality Measure Format (HQMF)[2] for the Measure Authoring Tool (MAT)[3], star schema and ontology for Informatics for Integrating Biology and the Bedside (i2b2)[4], and temporal abstraction ontology (TAO)[5] for Eureka! Clinical Analytics (Eureka)[6].

Materials and Methods

Phenotype algorithm: The "Methotrexate (MTX) drug-induced liver injury" phenotype algorithm shown in Figure 1 was selected for this evaluation task because it was a relatively simple algorithm that includes the complexity common to many more complicated phenotypes, such as, 1) multiple criteria (inclusion and exclusion), 2) multiple data types (diagnosis, medication, laboratory, etc.), and 3) temporal relationships.

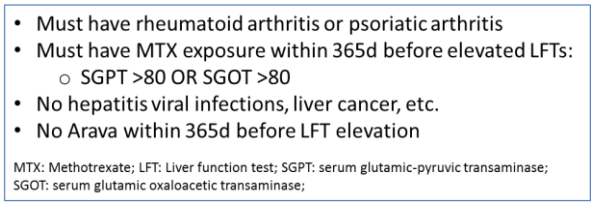

Figure 1. MTX drug-induced liver injury algorithm

Information model comparison: Three well-used phenotype authoring tools (MAT, i2b2 and Eureka) were explored in this study to identify gaps among the information models behind them by representing the MTX algorithm in each. QDM (used by MAT) is an information model describing clinical concepts in a standardized format. The star schema (used by i2b2) is designed to capture arbitrary data types and allow for rapidly developed analysis queries by incorporating with the i2b2 ontology (also called metadata) that is integral for querying the data. TAO (used by Eureka) provides a model for specifying phenotypes in terms of categories of codes, thresholds in value and slope, and both frequencies and sequences of both events and observations. During the implementation process, a list of major features for capturing semantics of phenotype algorithm has been identified and compared these three information models. The feature matrix for comparison is shown in Table 1.

Discussion In our evaluation, we have identified several strengths and limitations for the information models using in the three authoring tools. All of them have the capability to represent phenotyping algorithms for both machine and human consumption, and have their own advantages compared to the other two. For MAT, representation of terminology value sets within the QDM as code lists external to the measure definition, which are assigned a globally unique identifier, allows for their re-use. In addition, QDM requires strict definitions of value sets – code sets, code set version, a code and description for each entry. For i2b2, the query can be easily transformed and implemented against the backend clinical relational database. For Eureka, it includes well-defined temporal pattern types that cover a majority of temporal events occurring in phenotype algorithms. Phenotypes are composed from discrete building blocks (e.g., rheumatoid arthritis diagnosis codes, LFT value thresholds) that may be reused in other phenotypes. Additionally, we identified several limitations, including lack of support for specifying natural language processing (NLP) constructs and significant challenges in the ability to transform HQMF elements and components into executable queries (e.g., into SQL). These will be extensions proposed for future studies.

Allergies and Intolerances – Standards for Interoperability

Elaine J. Ayres, MS, RD[1], Russell Leftwich, MD[2], Lisa R. Nelson, MSc, MBA[3]
Laboratory for Informatics Development, NIH Clinical Center, National Institutes of Health, Bethesda, MD[1]; State of Tennessee, Office of eHealth Initiatives, Nashville, TN[2]; Life Over Time Solutions, Westerly, RI[3]

Abstract

The management and exchange of drug, food and environmental allergies and intolerances is essential for patient safety. Over the past several years, the international standards community has developed new models for the documentation and interoperability of allergies and intolerances. This panel will address new HL7 standards for adverse reactions, allergies and intolerances including V3 clinical models, FHIR resources and Consolidated CDA templates. Case studies will provide attendees with examples of how to represent key allergy and intolerance concepts including undifferentiated adverse reactions, reaction severity and condition criticality. The use of these concepts for quality measure reporting will also be discussed.

Learning Objective 1: Attendees will be able to describe the standards, data model attributes and terminology for documentation and interoperability of allergies and intolerances.
Learning Objective 2: Attendees will be able to compare and contrast Meaningful Use Stage 2 and 3 requirements for allergies and intolerances versus current HL7 documentation and transmissions standards including V3, FHIR and C-CDA models.

Introduction

Various information models exist for the representation of allergies and intolerances within electronic health records. HL7[1] has completed an extensive comparison of international models for the representation of adverse reactions, allergies and intolerances to create new international standards. This body of work has been balloted and published as a Domain Analysis Model along with Clinical Models for adverse reactions, allergies and intolerances. The HL7 Consolidated CDA (C-CDA) R1.1 standard includes section and entry level templates for the inclusion of allergy and intolerance data elements. The HL7 Fast Healthcare Interoperability Resources (FHIR) standard has been developed based on the V3 models. These standards now provide the EHR community with a variety of methods to document and exchange information on allergies and intolerances.

Standards for Stage 2 Meaningful Use and proposed standards for Stage 3 include the following core measure for medication allergies (§170.314(a)(7): *Medication allergy list - Enable a user to electronically record, change, and access a patient's active medication allergy list as well as medication allergy history: (i) in the Ambulatory setting over multiple encounters; or Inpatient setting for the duration of an entire hospitalization*[2]. Certified EHR systems use various formats for recording adverse reactions, allergies and intolerances. The "allergy list" may be a combination of observed or reported reactions (hives), or it may represent a condition such as "sulfa allergy". Lists may include both allergies and intolerances to medications, food, devices or environmental triggers. The list may represent a mix of concepts e.g. medications (aspirin), medication classes (analgesics), foods (peanuts), food groups (milk products), organisms (elm tree) or allergens such as elm pollen. Variations in concept representation and terminology binding have hindered interoperability and pose patient safety risks.

The following topical presentations will demonstrate available standards for the representation and interoperability of adverse reactions, allergies and intolerances. Audience discussion regarding current standards and issues will be sought following the presentations.

Elaine Ayres – HL7 Information Models for Adverse Reactions, Allergies and Intolerances Including FHIR Resources

In 2011, the HL7 Patient Care Work Group began a review of logical models related to allergies and intolerances. This review included models from the US Veterans Administration, Canada, Australia, the UK and the Netherlands. The development of a Domain Analysis Model with 15 use cases and functional models was balloted through HL7

in 2013 and published as an informative standard in 2014[3]. Clinical Models detailing the relationship of concepts were also developed and balloted in 2013 and published in 2014 as a Draft Standard for Trial Use (DSTU)[3]. This work represents the first universal standard for managing and exchanging adverse reactions, allergies and intolerances designed as well as support clinical decision support and quality reporting.

The HL7 V3 model for allergies and intolerances has several key concepts. In a clinical care episode when a patient presents with a symptom such as urticaria, the causative agent must be determined. Pending a clinical history, the classification of this event is an "adverse reaction". Therefore, the HL7 model uses the "adverse reaction" as the point of entry into documentation on the "list". Further clinical evaluation allows the reaction to be classified as an allergy or intolerance. The model proposes the use of substances to describe the causative agent of the adverse reaction. Based on current work of HL7, IHTSDO[4] and ONC[5], there is much discussion related to terminology bindings. At present the HL7 model is not prescriptive in this regard. Additions to the "list" may be represented as "reactions", the episodes reported by a patient, or as witnessed by the practitioners, or they may be represented as "conditions" such as a peanut allergy. Reactions may further be described with a severity classification. Conditions may include a clinical assessment of criticality. The model also describes the reconciliation of allergy and intolerance lists and the concept representation of "no known allergies or intolerances" or "unable to determine triggering agent".

FHIR is a next generation standards framework created by HL7[6]. FHIR modules (called resources) combine features of V2, V3 and CDA standards, with a strong focus on ease of implementation. A key component of a FHIR resource is the dependence on terminology binding. Resources for "adverse reaction" and "allergy and intolerance" are based on the constructs of the V3 model. The adverse reaction resource may be used as a singular concept e.g. hives with no known cause, or together with the allergy and intolerance resource. Data fields within the "list" also use the concepts of "substance" (with evolving terminology bindings), severity and criticality.

Russell Leftwich – Case study examples of adverse reactions, severity and criticality using HL7 models.

The historical model for the list of allergies and intolerances is the handwritten list on the front of a paper chart. This "list" might be a list of medications, occasionally a food or environmental substance and sometimes an annotation with an attribute, such as "severe". The interoperable exchange of this clinical data for the purposes of patient safety, clinical decision support, and quality metrics requires the use of a formal domain model that represents the essential information about reaction type, substance, and attributes that convey the criticality of the condition. This model is the basis for development of standards for exchange of clinical data[7].

Development of the HL7 standard is guided by use cases that portray the clinical scenarios, associated workflows, data requirements of recipients of information, and the associated semantic and process interoperability requirements. These use cases also serve as examples to inform adopters of the standard of its value and as guidance for implementation and integration into clinical workflows. Selected examples of use cases for adverse reactions, allergies and intolerances in this presentation illustrate these concepts[3]. A representation of these concepts within V3 messages and FHIR resources will demonstrate the utility to the EHR and transitions of care communities.

Lisa Nelson – Allergy and intolerance representation in standard digital documents

Exchange of standards-based interoperable data is the key to the successful communication of patients' allergy and intolerance information. It also is needed to automate the computation of quality measures designed to assess progress toward goals to improve availability of allergy and intolerance information in electronic health record (EHR) systems.

This presentation explains how allergy and intolerance information is represented in digital documents that conform to the HL7 Consolidated CDA (C-CDA) standard. It also shows how allergy and intolerance information in C-CDA format can be used to generate digital patient-level reports using the HL7 Quality Reporting Document Architecture (QRDA) standard—a standard used to supply data for the computation of performance toward quality measures. Participants will gain technical insight needed to understand and guide the adoption of systems that create and consume allergy and intolerance data, and measure its availability in EHR systems.

HL7 Clinical Document architecture, Release 2 (CDA R2) specifies a standard way to create digital documents for use in healthcare. CDA R2 was released in 2005. Worldwide, it is the most widely adopted application HL7 V3[8]. HL7 V3 applications all utilize the V3 Reference Information Model (RIM). The RIM is a data model which acts as a foundation upon which to build other models and standards so that implementations will produce data that is more interoperable. CDA documents offer a form of information exchange used in Meaningful Use. The presentation provides a rudimentary overview of the CDA R2 standard and familiarizes participants with the core principles and key characteristics of this standard.

Consolidated CDA Release 1.1 (C-CDA R1.1) is a set of 9 document templates and the associated section and entry templates used in the documents. The templates harmonize work done across HL7, HITSP[9], and IHE[10] to clarify previous designs that included inconsistencies. C-CDA provides a single set of templates which replace the prior work and support greater interoperability. Meaningful Use Stage 2 requires CDA documents conforming to the templates established by C-CDA R1.1. Several templates are included for representing allergy and intolerance information. The presentation reviews the available templates in C-CDA R1.1 for allergy and intolerance and changes proposed for C-CDA R2.0. Participants will see how current modeling compares to the actual templates defined in C-CDA and will discuss options for addressing gaps. A comparison of the V3 and FHIR templates versus the C-CDA models will also be included.

A Quality Reporting Document Architecture (QRDA) document is a special type of CDA document. QRDA is a document format that provides a standard structure with which to report quality measure data to organizations that will analyze and interpret the data. This standard includes a specific QRDA Category I DSTU designed to carry data based on Meaningful Use Stage 2 quality measures expressed in HQMF format. Health Quality Measure Form (HQMF) is a standard developed to express quality measures as "e-Measures". The presentation will familiarize participants with the 3 types of QRDA documents and describe their use in computing measures relevant to assessing available allergy and intolerance information.

Discussion Questions:

1. How are audience members currently recording allergy and intolerance data in their EHR's?
2. How do you define the term "allergy" when it is used as the header of an allergy list?
3. How should allergy and intolerance lists represent non-drug substances?
4. What are the preferred terminology bindings?
5. How do participants send allergy and intolerance data from provider to provider, or to the patient?
6. What enhancements should be made to these HL7 standards?

Disclaimer: All participants have agreed to take part in this panel.

There is Nothing as Practical as a Good Theory: Building the PCORNet Clinical Data Research Network

Charles Borromeo, MS[1], Bari Dzomba, MS[2], Mark G. Weiner, MD[3], Harold Lehman, MD[4]
[1]University of Pittsburgh School of Medicine, [2]Penn State Hershey College of Medicine
[3]Temple University School of Medicine, [4]Johns Hopkins University School of Medicine

Abstract : The goal of the Patient-Centered Outcomes Research Institute's (PCORI) National Patient-Centered Clinical Data Research Network (CDRN) Program is to improve the nation's capacity to conduct comparative effectiveness research (CER) efficiently, by creating a large, highly representative electronic data infrastructure for conducting clinical outcomes research. The creation of a sustainable network requires investment in information technology, adherence to data standards, development of sensible regulatory processes, and alignment with the clinical operations of the participating health systems. This Panel represents the members of the PaTH CDRN. Each member will describe their institution's baseline readiness and their development since the award. We will also describe key issues and insights we've experienced in creating our CDRN including choosing and using common data models, practical issues in applying data standards, and implementing inter-institutional query tools like i2b2, and addressing the regulatory and research informatics issues inherent to a multi-institutional research network

Learning Objectives :
Through participation in this panel, audience members will be better equipped to participate in a CDRN through an understanding of :

1. The impact of decisions regarding common data models on the types of research questions that can be addressed
2. Practical issues in mapping medication, diagnostic, and procedural terminologies to national standards
3. Implementation and use of i2b2 and PopMedNet for sharing queries and returning results across a network.
4. Regulatory and Research Informatics issues and solutions related to the development and application of clinical data research networks

Fundamental to the notion of a learning healthcare system is the ability to integrate comprehensive clinical data to continually generate and test evidence the helps support more informed decisions on the parts of patients and providers. To ensure generalizability of the findings, the clinical data needs to come from a broad range of providers, spanning different geography and covering patients of all ages, genders, races and socioeconomic status. The purpose of the PCORI CDRN program is to facilitate evidence generation through creation of a set of individual CDRNs that individually focus on a core set of disease areas, but can collectively work together to provide insight on a national scale into burden of disease, its management, and comparative effectiveness of therapies.

The PaTH CDRN is a collaboration between University of Pittsburgh/UPMC, Penn State, Temple University and the Johns Hopkins University, and their associated Health Systems. The collaborating institutions all have a history of clinical research experience and use of electronic health records, though variable experience with clinical research data infrastructure. Our success in developing the building blocks of a Clinical Data Research Network reflects our pragmatic approach to challenging issues in data integration, data standards, and implementation of networking, hardware and applications. Through a combination of didactic presentations and interactive discussion, this panel will help audience members understand the technical, administrative and financial issues in developing or participating in a CDRN.

University of Pittsburgh
Creating a *de novo* clinical research network presents a myriad of technical and logistical issues. Identifying appropriate software, developing a project management process, data ownership, and navigating the IRB issues are all required before the inter-site network can start to take shape. Complicating matters more, the PaTH Network faced a number of external networking requirements as a member of the PCORnet ecosystem. In response to these issues our network standardized on the i2b2 software platform and exchanged information across a VPN using SHRINE. We provide access to the PaTH data through the University of Pittsburgh's Comparative Effectiveness

Research Core Data Center (CERC-DC). The CERC-DC provides PaTH researchers with secure data storage, high-throughput computing allowing direct data analysis in a secure environment. The PCORnet data queries are conducted within the sites and the results are sent to the CERC-DC. Through this approach, we met the expectations of both our internal PaTH researchers and the needs outlined by the PCORI leadership. This discussion will illustrate the technical decisions and challenges faced when building a new research network.

Charles Borromeo, MS is a programmer at the Department of Biomedical Informatics (DBMI) at the University of Pittsburgh. He has led several academic development projects including FaceBase and the Biositemaps Resource Discovery System. Prior to his work at the University of Pittsburgh, he has spent over fifteen years working in informatics at several organizations like Pfizer and the Immune Tolerance Network. He holds a Master of Science degree in Biomedical Informatics from the University of Pittsburgh.

Penn State University
How does Big Data meet the Electronic Medical Record (EMR)? According to the American Society for Information Science and Technology, biological and health-based data are complicated, and require novel ways to acquire, process and disseminate the data efficiently. There can be barriers to successful implementations that need to be overcome before these data can be effectively and routinely managed. Healthcare research involving Big Data can pose a challenging set of problems that require the synergistic insights of cross functional teams, which include clinical, research, and information technology.

We understand the complex nature of acquiring, processing, and maintaining the health-based data from our EMR, billing, and specialty applications. Our team was ready to look at different data standards, understand the advantages and disadvantages of each, and be ready with contingency plans to overcome any risk associated with choosing one standard over another. As part of this collaborative effort, Penn State University had a unique challenge, in that our EMR system was different than all of our partner EMR systems. We successfully managed to overcome what could have been a barrier, and work through our own internal processes that were unique to us at a technology and organizational cultural level. From a commonality perspective, mapping the terminologies was a process the entire collaboration needed to do in sync with each other, and Penn State was able to make the modifications needed where we were unique, such as with the Cerner to NDF-RT to RxNorm mapping method. This discussion will focus on data standards and methods of mapping terminologies.

Bari Dzomba, Research Data Warehouse Program Manager at Pennsylvania State University College of Medicine, and Adjunct Faculty Pennsylvania State University Berks Division of Engineering, Business and Computing, has been in the Information Technology field for twenty years, and has twenty five years in the fields of education, healthcare, and information. Bari is currently the principal investigator on a mixed methods research study using a health-based social media dataset focusing on predicting leadership in online health and wellness communities as part of the dissertation requirements for her PhD at Alvernia University. She hold a Master of Science in Information Science from Pennsylvania State University Great Valley, and has held various leadership positions in the fields of healthcare, health insurance, and education.

Temple University
Agreement on a common data model (CDM) is often considered fundamental to the functioning of a research network. Consistent formatting of data across network members ensures that queries designed at one institution will run, at least syntactically, at other institutions. However, even with application of standardized vocabularies, there can be nuances in the recording of data that make interpretation and integration of query results from different institutions more challenging than it may seem. Furthermore, since institutions may have existing data warehouses in different formats, there are logistical issues in maintaining multiple versions of the data in different models. Lastly, as with many information standards, there are many CDMs to choose from, each one with purported advantages and disadvantages over others. This discussion will highlight several options in existing common data models, demonstrate their similarities and differences and provide a rationale for making an optimal decision about which one(s) to choose.

Mark Weiner, MD is Professor of Clinical Sciences, Assistant Dean for Informatics at the Temple University School of Medicine and the Chief Medical Information Officer for the Temple University Health System. He has a track record of work in clinical research databases through his earlier roles in the development of the PICARD

(Pennsylvania Integrated Clinical and Administrative Research Database) system at the University of Pennsylvania that integrates clinical and administrative databases in support of the clinical research enterprise; co-Chief of the Biostatistics and Informatics Core of the VA Center for Health Equity Research and Promotion,; and Co-chair of the Data Core of the FDA mini-Sentinel Initiative.

Johns Hopkins University
The recurrent question that arises in any multi-system work is, how do we maintain the meaning of the data as it is mapped and merged with data from other sources? We take the perspective that EHR data is bad research data, so we must start with understanding the sharing of research data. A recent IOM report lays out many of the issues, half of them involving protecting the research participant (in our case, patients in our centers) and the other half, data issues. CDISC and other organizations have been concerned with transmitting data with fidelity, while studies have shown that even mapping to standards can lead to incompatible results.

We addressed these issues in several ways. We will discuss how our process for defining common data elements balanced available metadata standards against the practicalities of extracting, storing, and sharing data of similar natures but different details, and balanced maintaining meta data, while not burgeoning the system either. All this, within an i2b2 framework.

Dr. Harold P. Lehmann, Professor of Health Sciences Informatics, Pediatrics, and Health Policy and Management, is a board-certified general pediatrician from Columbia University and Babies Hospital, with general pediatric fellowship training from Johns Hopkins and doctoral informatics training from Stanford. His research concerns evidence-based medicine (EBM), ranging from authoring reports to researching novel methods of delivering research results to opinion leaders and practitioners. He has served as a methodologist on a number of professional-society guidelines and has demonstrated the use of advanced decision-analytic methods in guideline development. His current work focuses on the informatics infrastructure of research, including research informatics support, ontologies for human studies and for appropriate inference from electronic health records, on evidence resources for community health workers, and on human (social) services informatics. In addition, he leads the Johns Hopkins efforts in informatics training across all three schools of health sciences, and is the faculty lead for the Informatics Core for the Institute for Clinical and Translational Research at Johns Hopkins. He has served as an Associate Editor for the Journal of the American Medical Informatics Association since 2011. He was elected a Fellow of the American College of Medical Informatics in 2006.

Discussion Questions :

We are interested in participating in a CDRN. What are the key justifications, assurances and processes you developed to gain the essential support of organizational leadership and Institutional Review Boards for CDRN participation?

The Meaningful Use 2 standards incentivize hospitals to standardize on terminologies like SNOMED, LOINC, and RxNORM. Conversely the current Medicare standard billing procedure uses NDC and ICD9 codes. Based on your experience, how should CDRNs reconcile multiple standards and what role can informatics play to help bridge this gap?

There are a number of PCORI CDRNs and related networks for patients called Patient-Powered Research Networks (PPRN). How do you ensure the ability to link your CDRN with these other centers?

All participants have agreed to take part in the panel.

AMIA POI-WG and Eval-WG sponsored panel

Imaginary and real costs of implementing HIT

Panelists

Mark Dente, MD[1], Andrea Gelzer, MD[2], MS, FACP, Ross Koppel, PhD, FACMI[3], Jos Aarts, PhD, FACMI[4]

Moderator

Catherine K. Craven, MLS, MA[5]

[1]Department of Veterans Affairs and University of Utah, Salt Lake City, UT; [2]AmeriHealth Caritas, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA; [4]Erasmus University Rotterdam, The Netherlands; [5]University of Missouri, Columbia, MO

Abstract

The costs of implementing HIT have always been shrouded in clouds. Cost estimates were always a kind of a back of the envelope calculations, with apparent clear figures for contracting such as license and consulting fees and hardware purchase and very unclear figures for the costs of involving the organization, such as releasing health care professionals from their day-to-day duties, production loss, etc. This panel aims to discern myth and reality, to summarize what little is known, to present hands-on experience to deal with costs and propose a multidisciplinary research agenda, involving health informaticists, health care professionals, social scientists and economists.

Introduction

The costs of implementing HIT have always been shrouded in clouds. Even though many remain optimistic about HIT's ultimate value, a recent publication cites a study that despite a "bribe of nearly $27 billion to digitize patient records, nearly 70% of physicians say electronic health record systems have not been worth it [1]." Poor functionality and high costs are quoted as the main reasons. Cost overruns are cited as a major reason for failed implementations [2]. A Gartner study reports that the actual lifetime cost of a system is estimated at 6.7 times the initial costs and consists of the components of enhancing the application (adding new features and new business needs), maintaining the application (bug fixes and software adaptation) and keeping the application operational (help desk, upgrading of computer systems and expanding storage capacity). On the other hand studies show that professionals spend more time managing their data on a computer system. It means that time spent at computer cannot be spent on other activities, such as caring for patients, a phenomenon that economists have termed the opportunity cost of choice. Poor HIT usability is blamed, but also the healthcare system requires professionals to account for their activities. The AMIA implementation discussion list testifies to the frustration of health care professionals spending so much time on what they call 'busy work.' In this way implementation of HIT can add to the cost that is not mentioned in the Gartner report. Proponents argue that the benefits lie in the increased quality, safety, efficacy and efficiency of health care delivery, but the verdict about the influence of HIT is still out [3]. The question however remains who are bearing the costs of HIT implementation and to whom accrue the benefits [4]. This panel seeks to discuss the issue, to separate myth and reality, to articulate the insights of administrators, who are increasingly cognizant of theses issues, and propose an agenda, how costs and benefits can be studied. The discussion will include following questions.

- What are the real and hidden costs of HIT implementation?
- Should contracting HIT be seen as purchasing a product or service?
- What additional costs can be identified in a contract?
- As systems mature, what is the role of performance guarantees?
- How does innovation related to HIT enter into the cost equation?

- What are the costs of poor usability?
- What benefits do the purchasers expect?
- To whom should cost and benefit accrue?

Panel members

- **Mark Dente, MD** is Deputy Chief Medical Informatics Officer at the Veterans Health Administration for Community IT Engagement and Staff Specialist at the Department of Biomedical Informatics of the University of Utah. Previously he was Chief Medical Officer for GE Healthcare Information Technology. He has been active in many areas, including interoperability, business development and intellectual property. He currently has a leadership role in the VA's VistA evolution. In Utah he works with faculty and students to innovate research and education.
- **Andrea Gelzer, MD**, **MS, FACP** is the Senior Vice President and Corporate Chief Medical Officer for AmeriHealth Caritas. She is responsible for medical management strategy, medical policy development, quality management, corporate provider network strategy and medical informatics for all AmeriHealth health plans.
- **Ross Koppel, PhD, FACMI** is a professor of sociology at the University of Pennsylvania. His field of expertise is sociology of work and research methods. In the former capacity he has studied extensively the impact of health information technology on healthcare professionals and addressed problems of HIT usability and safety. In his studies he found that doctors and nurses were not only frustrated by poor functioning IT, but spend a lot of time on entering data for clerical purposes. And that is adding to the costs of implementation.
- **Jos Aarts, PhD, FACMI**, Chair, POI WG, is assistant professor of biomedical informatics at Erasmus University Rotterdam. He has studied the implementation of HIT extensively and found that cost overruns and delays are quite common. Though sociotechnical perspectives inform his research, he thinks that the economics of health informatics is a research area that needs to be developed further.
- **Catherine K. Craven, MLS, MA (Moderator)**, Chair, EVAL WG, is a doctoral candidate in Health (Clinical) Informatics at the University of Missouri, Columbia, Missouri, USA. Her research covers HIT implementation processes in small, rural Critical Access Hospitals; technology impact on ICU clinical team communication; and she is a team member of the University of Missouri's CMS Health Care Innovations Challenge award program to leverage HIT to improve primary care coordination and patient engagement for better quality, care and cost outcomes.

Brief description of panelist presentations

Dr. Dente made the transition from a corporate vendor to the Veterans Health Administration that developed its own HIT software. He will address the business model of a vendor and compare with the HIT open source approach that is dominant in the Veterans Health Administration. Especially he will address the question how innovation enters into the cost equation [5].

Dr. Gelzer has implemented a population-based care management platform across her organization. As a payer, her organization is often called upon to financially support and play an important role in setting financial conditions for HIT adoption. The implementation costs to the payer to deliver population based clinical information across the care delivery continuum must also be considered.. AmeriHealth Caritas is involved in supporting Health Information Exchanges (HIEs). Her presentation will center on the role payers play, who accrues the costs and benefits of HIT and the expectation of a return on investment (ROI).

Professor Koppel's portion focused on implementation costs that are often unrecognized by hospitals and doctors because of complex bookkeeping (a polite term when referring to hospitals), because of the complexity of payment schedules to vendors, and, primarily because most of the costs are obscured in everyday operations of clinicians and the IT personnel. In addition, it is usually not in the interest of the C-suite leaders to display the full cost of implementation to either boards of directors or many staff. Regarding a monumental purchase—of often many hundreds of millions of dollars in software; and 3 to 5 times that in implementation costs—few want their purchase decisions to be show to be unwise or of uncertain ROI.

Dr. Aarts will pull together the insights of the panelists and will present a model developed by one of his students to determine the integral costs of implementation and validated in a case study of an EHR implementation in an outpatient clinic in Montréal, Quebec [6]. Her model identifies costs associated with developing organizational

capabilities, the pre-implementation phase, the implementation of a functional EHR, its optimization and finally post-implementation and operations.

Learning objectives

After participating in the session, the attendant should be able to:

- Formulate an approach to identify cost elements and cost allocations of HIT implementation in a healthcare organization.
- Evaluate cost elements of HIT implementation.
- Articulate a research agenda for biomedical informatics related to HIT implementation cost and benefits realization.

Conflict of interest

The participants have no conflict of interest to declare.

Abstract

The disciplines of public health and global health informatics are rapidly expanding within the field of biomedical informatics. Increased attention and activity by the Centers for Disease Control and Prevention in the U.S. as well as health ministries, the World Health Organization, and non-governmental organizations are generating new knowledge and lessons regarding the development, implementation, and use of information systems in health care delivery around the globe. Thus, a growing body of literature now contains important insights and lessons from international informatics activities, stimulating the need to synthesize the knowledge for the field. In this panel, a review of recent literature in the areas of public health and global health informatics will be presented. Key articles revealing trends, methods, and lessons will be summarized to bring attendees up-to-date on the use of informatics in low resource settings.

Introduction

At the AMIA 2013 Annual Symposium, Drs. Brian Dixon and Jamie Pina presented an inaugural AMIA panel presentation focused on summarizing recent literature in Public Health Informatics (PHI) and Global Health Informatics (GHI). The presentation was well-attended, and it broadened the topics covered by "Year in Review" sessions at the AMIA 2013 Annual Symposium. We seek to present a similar panel at the 2014 symposium. Our goal is to provide a concise overview of landmark papers in PHI and GHI for the year prior to the 2014 symposium using the methods described below. Furthermore, like last year, we will provide the output of our efforts as working documents available on the MyAMIA community site enabling attendees, as well as those who cannot physically attend, to leverage our work throughout the year.

Overview

The fields of public and global health informatics are expanding. In 2012, the PHI Fellowship Program administered by the U.S. Centers for Disease Control and Prevention (CDC) became a Department of Labor Registered Apprenticeship. PHI was also one of the six sub-disciplines of informatics specified in the ONC certificate programs funded between 2010 and 2013. As a result, publications in PHI have dramatically increased. This is evidenced by an increase in *Journal of the American Medical Informatics Association (JAMIA)* PHI articles, as well as the emergence of a journal dedicated completed to the study and practice of PHI, the *Online Journal of Public Health Informatics* (www.ojphi.org). Similar increases in programs and publications have been observed in the field of GHI. For example, Fogerty International fellowships now bring scholars from low-income counties to the U.S. for biomedical informatics training. The CDC also promotes a Global Public Health Informatics Program (http://www.cdc.gov/globalhealth/dphswd/gphip/what/objectives.htm) to build capacity and sustainability of health information systems world-wide. The impact factor and quality of publications in the *International Journal of*

Medical Informatics (IJMI) has also increased, leading to a significantly larger number of important papers published by non-U.S. scholars in informatics (1).

Given recent and continuing advances in PHI and GHI, an annual review of landmark publications in these sub-disciplines within the field of biomedical informatics is appropriate for the AMIA Annual Symposium. Two panelists (BED and JP) will each present a concise bibliography of recent landmark publications in either PHI or GHI. The session will be divided equally between PHI and GHI. A summary examining the convergence, synergies and possible future cooperation will be presented by the third panelist (JR). Time will be reserved at the end for discussion, question, and comments with the audience.

Methods

The methods used to select the literature in each part of the session are adapted from the work of previous AMIA Year in Review sessions. Our search methodology to identify potentially high impact literature in PHI and GHI is outlined below. The methods will be executed using MEDLINE and selected resources not currently indexed such as the conference proceedings of the International Society for Disease Surveillance. Recommendations will also be solicited from the AMIA PHI and GHI working group membership.

Candidate articles will be reviewed on a quarterly basis by a committee of experts in PHI and GHI, including Drs. Dixon, Turner, Kharrazi, Pina, and Richards, the Review's core team members. Additional input from the AMIA PHI and GHI working groups will be solicited. Selected articles from the list of candidates will be determined through consensus discussions on quarterly conference calls. Final lists of selected articles will be made available online via the MyAMIA site for reference following the symposium.

Public Health Informatics

To identify articles in PHI, we will use the following query (customized for MEDLINE):

"Public Health Informatics"[mh] OR ("exp Public Health"[mh] and "exp Informatics"[mh]) OR ("public health"[mp] and "informatics"[mp])

This query, when limited to publications between 1/1/2013 and 12/31/2013 in MEDLINE, returned 219 results. This is a reasonable set for the committee to review and discuss within a short timeframe.

In the presentation, Dr. Dixon will present the final selection of papers from the set of PHI candidate papers. Papers may be further categorized into themes, such as disease surveillance, population health, public health decision support, or chronic disease management depending on the list of candidate papers and the perspectives of the review committee. When reviewing the papers, Dr. Dixon will briefly describe their aim, methods, and key findings. Paper results will also be discussed in the context of larger PHI developments, such as the release (or study) of a specific system (e.g., Biosense 2.0) or change in public health infrastructure (e.g., re-organization of the CDC's division responsible for PHI). Context will help audience members connect specific study findings with larger trends within the biomedical informatics field of study and practice.

Global Health Informatics

To identify articles in GHI, we will use the following query (customized for MEDLINE):

("exp Informatics"[mh] OR "exp Telemedicine"[mh] OR "information system"[mp]) AND ("Developing Countries"[mh] OR global OR ministry OR "low resource" or "resource-limited"[mp])

This query, when limited to publications between 1/1/2013 and 3/13/2014 in MEDLINE, returned 345 results and was a reasonable set for the committee to review, analyze and discuss. Due a slightly shorter time-frame for publication of GHI-related research and activities, we plan to examine the "grey literature" and other non-traditional research sources, to acquire the depth and breadth of informatics activities globally in the past year.

In the presentation, Dr, Pina will present the final selection of papers from the set of GHI candidate papers. Papers may be further categorized into themes, such as mHealth, infrastructure, evaluation, capacity development, system implementation, etc. depending on candidate papers located and the review committee's assessments. The reviewers will briefly describe the paper's aim, methods, and key findings. Findings from the trends in the papers reviewed will also be discussed in context of global health or global informatics policy related activities, such as World Health Organization (WHO) guidelines, the US Congress reauthorization of the President's Emergency Plan For AIDs Relief (PEPFAR) and the increasing number of individual country eHealth Strategy Policy documents.

Following the PHI and GHI presentations, Dr. Richards will provide a summary to examine findings to provide context for possible PHI and GHI priority activities for the coming year. The session will end with discussion. Our experience from last year's presentation demonstrated that these related but unique sub-fields within biomedical informatics generate many interesting questions and comments from the audience and facilitate a dialogue between AMIA's international and domestic membership.

Discussion Questions

We will draw from the following discussion questions to engage audience participation:

- We found several interesting trends in knowledge generation within PHI & GHI over the past year. Which trend(s) were surprising to you?
- Projecting on what we have found, what do you think will be the biggest trend for 2015?
- What trends do you know of in GHI and PHI for the past year that may not have made it into the literature, yet?
- What initiatives, organizations and/or funding may exist to drive improvements in PHI & GHI research methods as well as dissemination and translation into practice?
- How can AMIA, especially the PHI & GHI working groups, better support the generation of new knowledge for research and practice in our respective disciplines?

Informatics without Borders: International Outreach of US-based Training Programs

Biomedical research and health services research have been increasingly relying on international collaboration. Team science has expanded beyond regional and national collaborations into an ecosystem of collaborators that are united by common goals through an electronic infrastructure for research. It has thus become important that all collaborators have adequate human and material resources to participate in international research networks. We will discuss how some biomedical informatics training programs based in the USA have been partnering with institutions from around the world to build capacity in informatics and have been empowering researchers with infrastructure and tools to participate in globalized biomedical research. We will cover (a) cultural and economic barriers for implementation of certain programs, (b) programs we developed to respond to the short- and medium-term needs of our international collaborators, (c) how we adapted existing research-enabling tools to facilitate research in developed and developing countries, and (d) how we adapted distance-learning and related technologies to facilitate this work. We will also discuss the importance of embedding international students in our training programs in the US, and the advantages that this type of diversity brings in terms of promoting broader cultural understanding that benefits all our faculty, students, and staff.

Panelists

1. Cynthia S. Gadd, PhD, MBA, MS, Professor and Vice-Chair for Educational Affairs, Department of Biomedical Informatics, School of Medicine, Vanderbilt University, Nashville, Tennessee

Title: Lessons Learned From an Indo-US Collaboration in Clinical Research Informatics Training

Vanderbilt University Department of Biomedical Informatics (VU-DBMI) and collaborators at the National Institute for Epidemiology (NIE) in Chennai, India envisioned the development of a clinical research informatics (CRI) program at NIE to include: (1) launching of a CRI certificate program at NIE utilizing best-in-class resources, including VU-DBMI and Indian faculty, with increasing responsibility for teaching by NIE scientists as their expertise grows; (2) establishment of an Indian CRI-REDCap Consortium Center to promote and support the use of next generation CRI in the service of clinical and translational research in India; and (3) development, through initial intense training and continuing education, of local CRI leaders at NIE, to fulfill the CRI-REDCap Consortium Center's education and research consultation missions. We will report and discuss the opportunities and challenges presented by this collaboration.

2. William Hersh, MD, FACP, FACMI, Professor and Chair, Department of Medical Informatics & Clinical Epidemiology, School of Medicine, Oregon Health & Science University, Portland, Oregon

Title: Adapting US-Centric Informatics Training to Expand Capacity in Low and Middle Income Countries

As emerging economies move from developing to developed status, the priorities for basic health care and public health take on additional burdens of behavioral/lifestyle aspects of health and chronic disease management. This management can be augmented by informatics. The

overall goal of our collaboration is to develop an informatics training program in global health that combines the existing strengths of the Department of Medical Informatics of Hospital Italiano de Buenos Aires (HIBA), Argentina and its established collaboration with the Department of Medical Informatics & Clinical Epidemiology (DMICE) of Oregon Health & Science University (OHSU) to develop a new focus in clinical and translational research informatics. We build upon the mutual strengths of both programs in the use of distance learning technologies to train researchers and informaticians, from single courses to entire fellowships. Attendees of the courses have gained knowledge to improve their research capabilities, while fellows have successfully started research careers in informatics.

3. Rebecca Crowley, MD, MS, Director, Biomedical Informatics Graduate Training Program, Associate Professor of Biomedical Informatics, University of Pittsburgh, Pittsburgh, Pennsylvania

Title: Enhancing Research and Informatics Capacity for Health Information in Colombia (ENRICH)

The collaboration between Javeriana University in Bogota, Colombia and the University of Pittsburgh has enabled the development of (1) on-site educational programs in Colombia and (2) certificate and master's training for Colombian clinicians, scientists and engineers in the Biomedical Informatics and Clinical Research training programs at the University of Pittsburgh. On-site activities have ranged from large multi-day courses, including a general review of Biomedical Informatics taught by a group of Pittsburgh and Javeriana faculty, to smaller focused workshops, including a short course in telemedicine. Colombian trainees in our program have worked on a variety of research projects in global health informatics, biosurveillance, and ontology development. A major focus of our partnership has been to help develop informatics capacity that builds on both technical and clinical expertise in Colombia. Cross fertilization with other global health informatics initiatives has provided unique opportunities for both Colombian trainees and other trainees of our training program.

4. Lucila Ohno-Machado, MD, MBA, PhD, Associate Dean for Informatics & Technology, Professor of Medicine and Chief, Division of Biomedical Informatics, School of Medicine, University of California San Diego, La Jolla, CA

Title: Brazil-Mozambique-US Collaboration in Biomedical Informatics and Bioinformatics

In partnership with the Federal University of Sao Paulo in Brazil and the Eduardo Mondlane University in Maputo, Mozambique, the University of California San Diego developed a series of programs to enhance local informatics training in areas in which gaps were noted and the application of the knowledge acquired in training was most feasible. In Brazil, a strong program in health informatics was extended to remote regions of the country via a tele-education program. In Mozambique, a series of short courses and symposia were developed to raise awareness of informatics in healthcare and biology. The courses in Mozambique were delivered in Portuguese by Brazilian collaborators. The symposia were offered with simultaneous translation into Portuguese. We will discuss lessons learned from these unique experiences as well as from training international students and postdoctoral fellows at UCSD.

Safety-Enhanced Design as a Meaningful Use Objective: Evaluating and Advancing the Usability of Electronic Health Records

Jan Horsky, PhD[1,3], Blaine Y. Takesue, MD[2,4], Rebecca Farr[5], Janet Campbell[6]

[1]Brigham & Women's Hospital, Boston, MA; [2]Regenstrief Institute, Indianapolis, IN, [3]Harvard Medical School, Boston, MA, [4]Indiana University School of Medicine, Indianapolis, IN, [5]Intermountain Healthcare, Salt Lake City, UT, [6]Epic Systems Corporation, Verona, WI

Abstract

Effective, safe and routine use of HIT by clinicians is predicated on the availability of well-designed systems that have excellent usability characteristics and can be integrated into common clinical workflows. The ONC has required, for the first time, that institutions and vendors developing EHRs submit results of summative usability evaluations as part of their application for Meaningful Use Stage 2 certification. The intent was to let developers show evidence of usability of their product so consumers could make informed purchase decisions. The expected content of each usability report was specified by the NIST in the Common Industry Format Template. However, the methods and extent of each evaluation study likely varied at each institution certifying their product. Panelists will discuss test studies, results and lessons learned for three home-grown EHRs – The Medical Gopher, HELP, and the Longitudinal Medical Records systems, and present a vendor perspective from Epic Systems.

Introduction

Effective use of health information technology (HIT) and continuing progress in its adoption by clinicians are the objectives of national policy initiatives in many countries.[1] The rationale driving the implementation of electronic health record systems (EHR) with advanced decision support is their potential to improve and monitor care quality and increase patient safety.[2] There is an emerging consensus among leaders in the industry, academia and government that a sustained positive effect of HIT can only be achieved by using systems that are specifically designed for the complex and dynamic healthcare environment, provide cognitive and decision support, have high standards of usability, advanced design of the human interface and can be integrated well into clinical workflows.[3]

The Office of the National Coordinator for HIT (ONC) has underscored the significance of human interface design as a core attribute of high-performing and safe information systems in Stage 2 of its Meaningful Use requirements for 2014.[4] It has added a requirement to report the results of summative usability evaluation and an attestation that development was done in accordance with a user-centered design process in order to receive ONC certification and CMS financial incentives. The intent was to help vendors and developers at academic and public institutions demonstrate the evidence of their product's usability in a format allowing both independent evaluation and comparison.[5] Test results are made public on the ONC website to allow consumers and procurers at large institutions to review and assess basic usability characteristics of systems they may consider purchasing. Developers may also use the insights and lessons learned from the testing to further refine the design of their systems and to focus on problem areas that may not have been previously identified.

The format and required content of reported results was specified in the Customized Common Industry Format Template[6] by the National Institute of Standards and Technology (NIST) but methods and extent of evaluations were not and likely varied by system and institution. For example, in the publicly accessible reports, the number of clinicians participating in observational studies varied from 5 to 30 and test settings, scenario content, the interpretation of results such as path deviations, type and severity of errors and task success or failure criteria were markedly different from one report to another and sometimes not described or reported. Evaluators were either hired usability professionals or experts from each institution.

The panelists will summarize and present their methods of evaluation and the results of summative studies they conducted in the process of generating data for submission to their respective certifying bodies. Each presenter will conclude with the lessons learned from the testing and significance of the results for their organization, insights to patterns of use by clinicians that may have not been previously known and what actions can be taken to address limitations, problems or observed workarounds by future redesign of specific products.

Urgency, timeliness and significance of HIT usability evaluation

Usability test results and user-centered design (UCD) attestations were new requirements for Stage 2 this year and the topic is therefore timely and of interest to most organizations, private and commercial, that had to go through this process relatively recently and for the first time. Consumers have now a new source for examining the results of usability evaluations for systems they either own or plan to buy and can compare them across vendors. This practice is recommended and encouraged by an HIMSS usability task force[7] but has been relatively difficult to carry out. The publicly available results are now more likely to encourage prospective buyers to include usability criteria more prominently and with greater confidence as factors in purchasing decisions. Usability is frequently cited by clinicians as a highly desirable characteristic of an EHR, strongly affecting their productivity and time spent documenting care, but by many accounts often lacking in current EHRs. There is considerable research evidence of positive correlation between the quality human-computer interface design and patient safety[8, 9] and that poorly designed HIT may not only slow down clinical work but may increase the risk of medical error.[10]

Panelists

The proposed panel consists of 15-minute presentations by each participant, followed by a moderated discussion.

Jan Horsky, PhD (organizer)

Dr. Horsky leads research in human-computer interaction at Partners HealthCare in Boston and conducts periodic formative and summative usability evaluations of information systems that are developed and maintained internally, primarily the Longitudinal Medical Record (LMR) system. The LMR is used daily by over 5,000 physicians in diverse ambulatory settings ranging from small community practices to hospital-based ambulatory centers. His research is concerned with cognitive aspects of human-computer interaction in dynamic healthcare environments, usability evaluations of HIT, and with the effects of clinical information systems on the quality of care and medical error. Past projects include a cognitive usability study of clinicians interacting with a computer-based provider order entry system (CPOE), and the evaluation of a serious medication dosing error that was in part related to the use of a CPOE system. He led the Safety Enhanced Design effort for the certification of inpatient and outpatient systems at Partners. Dr. Horsky is Instructor in Medicine at Harvard Medical School and adjunct faculty at Usability and User Experience Program at Bentley University in Waltham, MA.

Blaine Y. Takesue, MD

Dr. Takesue is the clinical lead for the re-engineered version of the Regenstrief Gopher CPOE. It is currently deployed throughout the Eskenazi Health system, including its hospital and outpatient clinics and used by more than 800 providers to write over 7,000 notes and orders daily. Dr. Takesue also leads the Gopher Meaningful Use certification process and the Meaningful Use attestation/reporting effort for Eskenazi Health. His areas of interest include improving CPOE user experience and combining theory, technology and infrastructure to transform data into knowledge to address clinical concerns and to improve provider and patient health care experiences. Dr. Takesue is Assistant Professor of Clinical Medicine at the Indiana University School of Medicine.

Rebecca Farr

Ms. Farr has 35 years of healthcare experience, including administrative management, information technology, quality assurance and government regulations and compliance. Her expertise is in requirements and design analysis, along with operationalizing large, highly-integrated projects. Her recent focus has been on facilitating the enhancement of Intermountain Healthcare's clinical systems to meet ONC HITECH Certification requirements and to support the clinical workflows required to meet CMS Meaningful Use regulations. The inpatient clinical system (HELP1) and ambulatory clinical system (HELP2) were tested for certification. HELP was the first hospital information system to collect patient data needed for clinical decision-making and at the same time incorporate a medical knowledge base and inference engine to assist clinicians in decision making.

Janet Campbell

Ms. Campbell is Senior Software Architect at Epic Systems Corporation, an EHR vendor for mid-size and large medical groups, hospitals and integrated healthcare organizations. She has led over the last eleven years development of products such as the Stork Obstetrics module, Lucy personal health record, and MyChart Bedside shared record for hospitalized patients. Ms. Campbell represents Epic in national conversations on interoperability, usability, meaningful use, and patient engagement and is Vice Chair of the Electronic Health Record Association's Clinical Experience Workgroup.

Vimla L. Patel, PhD, DrSc (Moderator)

Dr. Patel is Senior Research Scientist and Director of *Center for Cognitive Studies in Medicine and Public Health* at the New York Academy of Medicine, with adjunct appointments at Columbia and Cornell Universities as Professor of Biomedical Informatics and Public Health, respectively. Trained as a cognitive scientist at McGill University where she served as Professor of Medicine and Psychology, her research focuses on modeling medical decision-making and on cognitive mechanisms underlying human performance in health care. Her recent studies focus on complexity of distributed cognitive systems that underlie critical care decisions, generation of medical errors and on the impact of technology on human cognition for competent performance.

An elected fellow of the Royal Society of Canada (Academy of Social Sciences), the American College of Medical Informatics, and the New York Academy of Medicine, she was a recipient of the annual Swedish "Woman of Science" award in 1999. She received an Honorary Doctor of Science degree from the University of Victoria in 1998, in recognition of her contributions through cognitive studies in the domain of health informatics. She is an associate editor of the *Journal of Biomedical Informatics* and sits on the editorial boards of *Artificial Intelligence in Medicine* and *Advances in Health Science Education*.

Discussion topics and questions

- This panel reviews three home-grown systems and a vendor system. Can methods, lessons learned and results be compared across vendor systems and commercial applications intended for small private clinics?
- Three systems are at institutions of different sizes: two large networks consisting of multiple hospital, clinics and private practices (Partners and Intermountain) and a smaller system consisting of the Eskenazi Hospital and over 20 mostly community based clinics (Regenstrief). How did the evaluations differ in scope, size of the test sample cohort and interpretation of the result? Are they directly comparable?
- How did institutions decide between evaluating systems internally and contracting usability professionals?
- What design changes are planned based on the findings from each study?
- What results were unexpected or surprising? Were any unintended effects observed?
- What new insights did he evaluators learn and how were they reformulated in to redesign projects?
- What was the time and effort required at each institutions to collect data and generate the report?

The Clinical Quality Framework Initiative: Harmonizing Clinical Decision Support and Clinical Quality Measurement Standards to Enable Interoperable Quality Improvement

Organizer: Kensaku Kawamoto, MD, PhD, MHS

Panelists
Kensaku Kawamoto, MD, PhD, MHS[a]
Marc J. Hadley, PhD[b]
Kate Goodrich, MD, MHS[c]
Jacob Reider, MD[d]

Panelist Affiliations
[a] Department of Biomedical Informatics, University of Utah, Salt Lake City, UT
[b] MITRE Corporation, Boston, MA
[c] Centers for Medicare & Medicaid Services, Washington, D.C.
[d] Office of the National Coordinator for Health IT, Washington, D.C.

Abstract
Clinical decision support (CDS) and electronic clinical quality measurement (eCQM) are closely related and share many common requirements. However, CDS and eCQM standards were developed in parallel and utilize different approaches for representing patient information and computable expression logic. This divergence imposes additional burdens on users of the standards and limits the ability to cross-leverage eCQM resources for CDS, and vice versa. To address this important problem, the Office of the National Coordinator for Health IT (ONC) and the Centers for Medicare & Medicaid Services (CMS) are sponsoring an open, public-private collaborative effort to establish a single, harmonized set of standards for CDS and eCQM. This effort, known as the Clinical Quality Framework (CQF) initiative, is developing and validating common standards for representing patient data, expression logic, and metadata for the purposes of quality improvement. Moreover, CQF is re-factoring existing CDS and eCQM standards to utilize these common components. In this panel, CQF leaders – including the Deputy National Coordinator of ONC and the Director of Quality Measurement at CMS – will provide an overview of CQF, its methodology, and its deliverables. Standards developed and validated through CQF will be available to policy makers for potential inclusion in future EHR certification requirements.

Description
The panel will be organized as follows:

Time	Speaker	Topic
10 min	Reider	ONC perspective on motivation and goals for CQF
10 min	Goodrich	CMS perspective on motivation and goals for CQF
20 min	Hadley	Overview of CQF and its methodology Harmonization of metadata Harmonization of expression logic

Time	Speaker	Topic
20 min	Kawamoto	Harmonization of patient information model Updates to existing CDS and eCQM standards to utilize harmonized components Pilot implementations Summary of current status and future directions
30 min	Reider	Panel discussion with audience

Dr. Reider will serve as the moderator and introduce each of the panel members and their organizations. He will also describe the motivation and goals underlying ONC's sponsorship of the CQF initiative. Dr. Goodrich will then describe the motivation and objectives of the effort from the perspective of CMS. Dr. Hadley will provide an overview of the CQF initiative and its methodology. He will then describe how metadata and expression logic for CDS and eCQM are being harmonized. Dr. Kawamoto will then describe how a common patient information model is being developed for CDS and eCQM, as well as how existing CDS and eCQM standards are being updated to utilize these harmonized component standards. He will then describe pilot implementations of the standards, summarize the current status of CQF, and outline planned future directions. These presentations will be followed by a panel discussion with the audience moderated by Dr. Reider.

Reider: Dr. Reider is the Deputy National Coordinator of ONC. Prior to his leadership role at ONC, Dr. Reider was the Chief Medical Informatics Officer of Allscripts. Dr. Reider will moderate the session and discuss the motivation behind the ONC initiating and sponsoring the CQF initiative.

Goodrich: Dr. Goodrich is the Director of the Quality Measurement and Health Assessment Group at CMS. In this role, Dr. Goodrich oversees the implementation of 12 quality measurement and public reporting programs and partners with CMS components on several other programs. She continues to practice clinical medicine as a hospitalist and Associate Professor of Medicine at George Washington University Hospital. Dr. Goodrich will discuss the motivation and objectives underlying CMS's sponsorship of the CQF initiative.

Hadley: Dr. Hadley is Principal Software Systems Engineer at MITRE Corporation, an expert on eCQM, and co-Initiative Coordinator of the CQF initiative. Dr. Hadley will provide an overview of the CQF initiative and its membership. Dr. Hadley will also describe the systematic methodology of the CQF initiative, which utilizes the ONC's Standards & Interoperability Framework for developing and validating interoperability standards. He will also describe core principles of the CQF initiative, which include collaboration, transparency, and pragmatism. He will then describe the CQF initiative's efforts to develop common standards for metadata and expression logic for CDS and eCQM.

Kawamoto: Dr. Kawamoto is Associate Chief Medical Information Officer, Assistant Professor of Biomedical Informatics, and Director of Knowledge Management and Mobilization at the University of Utah. Along with Dr. Hadley, Dr. Kawamoto is co-Initiative Coordinator of the CQF initiative. Previously, he served as the Initiative Coordinator of the ONC Health eDecisions initiative, which developed the CDS standards being harmonized with eCQM

standards in the CQF initiative. Dr. Kawamoto will describe the CQF initiative's efforts to develop a common patient information model standard for CDS and eCQM, which includes the development of a common logical model known as the Quality Information and Clinical Knowledge (QUICK) model, as well as a physical model based on the HL7 Fast Healthcare Interoperability Resources (FHIR) standard. He will then describe how these common standards for patient information, metadata, and expression logic are being incorporated into relevant CDS and eCQM standards, namely the HL7 CDS Knowledge Artifact Specification, the HL7 Decision Support Service Implementation Guide, and the HL7 Health Quality Measures Format (HQMF). Dr. Kawamoto will also describe experiences with pilot implementations of these standards and conclude with a summary of the current status and future directions of the CQF initiative. Interoperability specifications within the scope of the CQF initiative are planned for balloting in HL7 in September 2014, and the standards developed and validated through CQF will be available to policy makers for potential inclusion in future EHR certification requirements.

Reider: Dr. Reider will lead a moderated discussion with the audience. The objectives of this discussion will be to answer questions from the audience and to obtain feedback from the audience to guide the future directions of the CQF initiative and related efforts. The discussions questions listed below will be used to stimulate this discussion.

Significance of panel topic and anticipated audience

Current and proposed EHR certification requirements associated with the U.S. Meaningful Use program include requirements for divergent CDS and eCQM standards. The CQF initiative is seeking to expeditiously address this important challenge by developing and validating a unified set of standards for CDS and eCQM. Of note, the results of the CQF initiative will be available to federal policy makers for potential inclusion in future EHR certification requirements. Therefore, the panel topic is timely, urgent, needed, and of great significance to the clinical informatics community. The anticipated audience is AMIA attendees interested in CDS, eCQM, and/or Meaningful Use and associated EHR certification criteria, including members from academia, the public sector, and private industry.

Discussion questions

What suggestions do you have for the CQF initiative and related activities, such as EHR certification requirements for CDS and eCQM?

What gaps still exist in the available standards related to CDS and eCQM? How should we address those gaps?

What clinical domain areas can most benefit from standards-based, interoperable CDS and eCQM (e.g., immunizations, chronic disease management, chemotherapy)?

How should CDS and eCQM be leveraged in the short-term and long-term to improve clinical quality and health outcomes?

Participation statement

All proposed panelists have agreed to participate in the panel if the proposal is accepted.

Acknowledgements

The CQF initiative is supported by funding from the ONC and CMS, as well as by voluntary contributions of effort from various members of the CQF community.

Genomic dark matter, druggability and misunderstood targets

Subramani Mani, MBBS, PhD[1,4]

Joshua Swamidass, MD, PhD[2]

Noel Southall, PhD[3]

Tudor Oprea, MD, PhD[1]

[1] Division of Translational Informatics, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM

[3] National Center for Advancing Translational Sciences (NCATS), Rockville, MD

[4] Panel organizer

Researchers and pharmaceutical companies have typically focused on a small part of the genome-encoded proteome for drug targeting thus shedding light on these regions from a druggability perspective while leaving large tracts of the genome-encoded proteome or exome dark. This panel will introduce the concepts of genomic dark matter, druggability of genes/proteins and misunderstood targets. We will also introduce an in-silico framework for illuminating the druggable genome by discussing the approaches taken for the creation of the Illuminating the Druggable Genome Knowledge Management Center (IDG KMC) and the Target Central Resource Database (TCRD). TCRD will serve as a go to resource for developing a mechanistic understanding of a newly discovered set of biomarkers for a clinical condition from a druggability perspective and this will be illustrated in the panel presentation using the set of ranked biomarkers identified for early detection of neonatal sepsis. In short the proposed panel will discuss effective strategies for shedding light on the dark matter of the druggable genome to identify useful and effective drug targets.

Learning objectives:

1. Understand the concept of druggability
2. To learn how to define drug targets
3. Understand the concept of genomic “dark matter” from a druggability perspective
4. Understand how the genomic dark matter can be “illuminated” from a druggability perspective

From a druggability perspective large tracts of the exome, that is, the proteins encoded by the genes in the exome have been left unexplored and hence “dark”. Based on their review of literature Hopkins et al. report that 399 non-redundant molecular targets have been shown to bind efficaciously with small molecules[1] out of more than 10,000 likely such targets in the human genome based on projections of ligand binding domains[2]. The challenge is to identify the relevant subset of the potential druggable targets that are represented in disease-linked

proteins. Note that approximately ninety percent of the currently marketed drugs interact with the various proteins encoded by the genes represented in the exome[3].

Dr. Joshua Swamidass, MD, PhD: What is the meaning of druggability?

Modern genome-wide technologies—that study all the proteins in the genome—can identify genes mechanistically related to human disease. One hope in these studies is to identify new drug targets, genes that can be pharmaceutically modulated to treat disease. However, only a fraction of genes can be effectively targeted with a drug. In other words, only a fraction of genes are translated to proteins that are considered “druggable.” How is druggability determined and defined? There are, actually, several approaches to answering this question. Here, we will present several common approaches, and examine their implications for interpreting genome-wide analysis and drug discovery.

Dr. Noel Southall, PhD: Misunderstood targets

There is a high failure rate for drugs in clinical development, and an inability to adequately predict whether a drug will be efficacious. To better increase the chances of success in the clinic, one can choose to work solely on clinically validated targets. The other option is to choose to work on novel targets from those classes of proteins that have had success in the past, such as G-protein-coupled receptors (GPCRs), kinases, and ion channels. Will this strategy improve the chances of success? Different classes of targets have different liabilities, especially the problem (or benefit) of polypharmacology which is not easily addressed. The recent practice of developing allosteric compounds to avoid the problems of polypharmacology introduces new unknowns that can also send one right back to the beginning. And there are gaps in understanding how drugs work even after their marketing authorization. Here we consider some details of target validation and try to add another level of sophistication into the target druggability debate.

Dr. Tudor Oprea, MD, PhD: Illuminating the Druggable Genome Knowledge Management Center (IDG KMC) and the Target Central Resource Database (TCRD)

The goal of the Illuminating the Druggable Genome Knowledge Management Center (IDG KMC) is to evaluate, classify and rank all the disease-linked proteins based on their potential as druggable targets. The main focus will be on the four protein superfamilies: G-protein-coupled receptors (GPCRs), nuclear receptors (NRs), ion channels (ICs) and kinases. By integrating data extracted from multiple sources using algorithmic processing, prediction and human curation, the emerging knowledge base will hyperlink and annotate all the relevant proteins. The KMC will link disease, pathway, protein, gene, chemical, bioactivity, drug discovery and clinical information elements from databases, literature, patents and other documents in a "Target Central" Resource Database (TCRD). Based on this rich knowledge representation we will be able to categorize proteins into four classes (Tclin - clinical; Tchem - manipulated by chemicals; Tmacro - manipulated by macromolecules; and Tdark - the genomic "dark matter") and enable efficient and effective target prioritization for new therapeutics as the knowledge base grows and develops.

Dr. Subramani Mani, MBBS, PhD: Proteomic biomarker druggability profiling using the domain of neonatal sepsis

A set of predictive, diagnostic or prognostic biomarkers relevant to a specific clinical condition or disease can be identified using focused literature search or obtained from research studies designed specifically for biomarker discovery. While these biomarkers may play an effective role in early detection, diagnostic evaluation or for assessment of prognosis, a mechanistic understanding is needed to ascertain if any of these biomarkers can be targeted from a druggability perspective to eventually move the biomarker(s) to the realm of therapeutics. Using pathway analytics and the TCRD resource component of IDG IMC we will try to show which of the neonatal sepsis biomarkers identified from the bio-signature study of neonatal sepsis conducted at the University of New Mexico Children's Hospital can serve as potential therapeutic targets for further evaluation from a drug development perspective.

Researchers are evaluating the scope, promise and potential of genomic medicine from different perspectives such as genetic risk quantification for diseases, determination of drug efficacy and dosage based on genetic profiling and for predicting adverse drug reactions. However, the major challenge in moving towards genomic medicine is to identify new targets of therapeutic value so that newer drugs can be developed to treat various diseases promptly and effectively for which no effective pharmaceutical interventions are currently available. The proposed panel will shed light on this challenge of moving genomic medicine forward from a therapeutic perspective.

The target audience for this panel will be researchers in the domains of clinical informatics, translational bioinformatics (broadly defined), drug discovery and pharmacogenomics. The panel discussion would be of interest to researchers in academia and industry.

Discussion questions:

1, What is druggability and druggability profiling?

2. What exactly are drug targets?

3. How do you define drugs from a druggability perspective?

4. Why has the new drug development pipeline slowed down considerably?

5. How will the IDG KMC accelerate new drug development efforts?

The panel organizer has personally contacted all the other panel participants and they have agreed to take part in the panel.

Abstract

Within the next one to two years, we can expect to have over 100,000 genomes sequenced. Many of these genomes will belong to patients for whom we have extensive medical records. This will present an opportunity to find rapid associations of genotype to phenotype and exercise precision medicine. It is sobering therefore to learn that although we are poised to take advantage of the explosions of genomic data as well as the data from our healthcare enterprise, that there are few approaches to data representation that allow us to query the two types of data in unison. Although genome browsers at UCSC, Ensembl, and the National Center for Biotechnology Information (NCBI), as well as the model organism databases (e.g., Wormbase, Flybase, Saccharomyces Genome Database (SGD), and Mouse Genome Database (MGD]), have become essential tools for the analysis of genomic, molecular biology data, the representation of phenotypic data is unable to accommodate the complex representations of human phenotypes as exists in our healthcare system [11]. In the same way, typical representations of healthcare data in both transaction-based electronic medical records (VISTA, OpenEMR), as well as analytic healthcare models (mini-sentinel, virtual data model, and observational medical outcomes partnership) do not accommodate genomic data with any facility [12].

In this panel we will discuss and present three approaches that have been taken within the i2b2 community to approach the implementation of a genomic-phenomic query capability. These three groups agreed to contrast their approaches using a standard dataset to illustrate their specific approaches and tradeoffs.

For a first benchmarking of genomic and clinical data integration on the i2b2 platform, we focused on common data types and their basic usage. The goal of the three teams was to integrate whole exome variation data with human phenotype data, to enable smooth, intuitive, and rapid querying of both phenotypic and genomic variables. Whole exome SNPs and indels were extracted from The 1000 Genomes Project's Phase 1 Integrated Release [1] using The Genome Analysis Toolkit [2] and annotated using ANNOVAR [3] Cellular phenotype data collected on the same individuals was obtained from Wu et al. [4]. The teams were then asked to apply their method to answer the following basic use cases:

1. Which individuals with a lower mode of HLA-DQB1 protein levels (i.e. HLA-DQB1 log protein ratio < 0) have missense or nonsense mutations in that gene?
2. How many individuals with log HLA-DQB1 protein ratio < 0 have probably damaging missense mutations in that gene, as determined by PolyPhen-2 [5]?
3. How do the above answers change if we select just YRI (Yoruban) or CEU (European individuals)?
4. How many individuals carry variants previously implicated in hypertrophic cardiomyopathy, but recently found to be quite prevalent in normal populations [6]?

The ability for the platforms to address these use cases helps to evaluate the real-world utility of the data representations and query software. Each approach is now described in detail:

Approach 1: classic i2b2 data representation – Lori Phillips

The classic i2b2 data representation uses the standard Sequence Ontology (http://www.sequenceontology.org/) represented within the format of the i2b2 ontology. The ontology organizes a set of concepts describing the structural change of the variant, such as a "Single-nucleotide polymorphism: SNP/SNV, or the insertion or the deletion of bases: Indel. Then the attributes of the structural variation are expressed as "modifiers" for that variant, such as numbers representing the location of the variant, the gene in which the variation is thought to occur, whether it is synonymous, and perhaps the PolyPhen-2 score of the variation which predicts the biological effect on the function of the gene protein.

The main features of this approach are:

1. Flexibility to create queries that mix phenotype and genotype information in the visual interface of i2b2 where Boolean queries are represented. These queries can be created in real time, and answers returned in seconds from tables with millions of structural variants.
2. Variant information that is loaded directly from an ANNOVAR output file, which fully represent detailed annotations on millions of variants.
3. Ability to represent fully annotated structural variants in a simple to use query interface.

Approach 2: tranSMART – Paul Avillach

TranSMART is an open source knowledge management platform that enables scientists to develop and refine research hypotheses by investigating correlations between disparate data sources [7]. This open source platform is an i2b2 spinoff created in 2008 by Johnson & Johnson in the context of clinical trials [8]. On top of i2b2 the tranSMART application adds lightweight analytic capabilities, an expandable analysis framework and many data management options. We developed an analytic and integration pipeline to load ANOVAR variant annotations in tranSMART

The main features of this approach are:

1. The ability to create fine-grained phenotypic queries against fine-grained genomic information
2. R and Bioconductor analytics extend the i2b2 functionalities.
3. The visual dashboards enables the generation of multiple hypotheses.
4. Using SQL*Loader permits all the genomic data to be loaded very quickly into the Oracle database.

Approach 3: NoSQL – Matteo Gabetta

The i2b2+NoSQL approach extends the i2b2 platform in order to query both phenotype and genotype data by using two databases: the standard i2b2 warehouse to store phenotypes and CouchDB [9], a NoSQL document store, for genetic variants.

The main features of this approach are:

1. The flexibility and scalability provided by NoSQL databases in general and by CouchDB in particular. CouchDB is based on a schema-less data model: it stores one JSON document for each patient's variant containing all the associated data. Moreover, it scales very well when the data volume increases [10]).
2. Very fast query times, provided by an indexing system built on the JSON files.
3. The automatic creation of JSON files from a set of multi-sample VCF files
4. The opportunity to separately tune the two databases, given the uneven nature of the data they are entrusted to manage.
5. The system is thus based on two parts: data annotation/upload and data query.

Discussion questions

- The panel will show the results of the three approaches on the case studies,
- It will discuss the main similarities/differences between the three approaches
- It will show the strong and weak points of the 3 approaches
- It will emphasize the costs, in terms of time and computational resources

Panel organizer and participants

The panel is organized by Shawn Murphy and Riccardo Bellazzi, and the panelists are Lori Phillips, Paul Avillach, Matteo Gabetta. The panel organizer declares that all participants have agreed to take part on the panel.

Abstract

Natural Language Processing (NLP) of clinical free-text has received a lot of attention from the scientific community. Clinical documents are routinely created across health care providing institutions and are generally written in the official language(s) of the country these institutions are located in. As a result, free-text clinical information is written in a large variety of languages. While most of the efforts for clinical NLP have focused on English, there is a strong need to extend this work to other languages, for instance in order to gain medical information about patient cohorts in geographical areas where English is not an official language. Furthermore, adapting current NLP methods developed for English to other languages may provide useful insight on the generalizability of algorithms and lead to increased robustness. This panel aims to provide an overview of clinical NLP for languages other than English, as for example French, Swedish and Bulgarian and discuss future methodological advances of clinical NLP in a context that encompasses English as well as other languages.

General Description of the Panel

The goal of this panel is to engage the medical informatics and clinical Natural Language Processing community in a discussion about ways to advance research through languages other than English. We will provide an overview the current state of clinical NLP in a variety of European and non-European languages as well as focused reports on French, Swedish and Bulgarian. We will motivate the need for developing clinical NLP in languages other than English by the potential for methodological and medical advances. Finally, we will propose strategies to contribute to advance work on languages other than English and integrate it in a state-of-the art platform.

Clinical NLP in languages other than English

Natural Language Processing (NLP) of clinical free-text has received a lot of attention from the scientific community, demonstrating its potential to provide the means to analyze large quantities of documents rapidly and accurately (Demner-Fushman et al. 2010). Prime clinical applications for NLP include assisting healthcare professionals with retrospective studies and clinical decision making. The ability to analyze clinical text in languages other than English opens access to important medical data concerning cohorts of patients who are treated in countries where English is not the official language. Recently, Kohane et al. (2012) also showed the impact of methods allowing an aggregated exploitation of clinical data. In this context, data extracted from clinical texts in languages other than English adds another dimension to data aggregation.

As the importance of clinical NLP gains recognition, clinical corpora become available to researchers in languages other than English, prompting work that sometimes builds on methods validated for English. Adapting systems that work well for English to another language is a difficult task that may be carried out with varying level of success depending on the task and language (Grouin et al., 2009; Velupillai et al. 2014; Täckström et al., 2012). For non-European languages, approaches that account for entirely different word and sentence structures sometimes need to be developed (Shinohara et al. 2013), and cultural differences between clinical narrative styles accounted for (Wu et al. 2013). Access to terminologies and corpora in languages other than English can also be challenging (Schulz et al. 2013; Xu et al. 2013). These experiments prompt a reflexion on how to carry out clinical NLP in a more global context: should methods be developed for one language and then ported to other languages? Can the source language method benefit from the porting? Can algorithms be more robust if they are designed with a multi-language perspective from the start?

French is widely spoken around the world and benefits from one of the largest coverage in the UMLS. Automatic de-identification is becoming quite advanced for French (Grouin & Névéol, 2013), leading to good results for targeted clinical information extraction tasks (Deléger et al. 2010; Grouin et al. 2011). Recent efforts from the French biomedical Informatics community have addressed rules and regulations to improve the access of NLP researchers to clinical corpus. Furthermore, the success of initiatives such as that reported by Grouin et al. (2011) increased the awareness of the potential implication of clinical NLP in clinical practice and contributed to making the timing ripe for making clinical corpus available for annotation and NLP tool development. On-going efforts currently address the annotation of clinical corpora for entity, modality and relations. Tools are being designed for information extraction as well as semantic indexing, information retrieval and clinical data visualization.

Much of the research in **Swedish** clinical NLP has used the Stockholm EPR Corpus, (Dalianis 2012), that contains more than one million patient records encompassing the years 2006-2010, from over 550 clinical units origin from Karolinska University Hospital. Part of this corpus has been manually annotated for Protected Health Information, negations, uncertainty levels, symptoms, diseases, drugs, body parts and abbreviations. The annotated corpora have been used both for training of machine learning systems and evaluation. Some applications are explorative as comorbidity networks, warning and reporting systems detecting hospital acquired infections or adverse drug events, but also work on text simplification of patient record content for the layman patient, (Dalianis 2012). Tools that have been developed for this is an adaptation of NegEx for Swedish (Skeppstedt 2012), a system for classifying terms into six levels of assertion levels pyConTextSwe, (Velupillai et al. 2014), abbreviation detection, (Isenius et al. 2012) and machine learning system based on CRF++ that recognizes named clinical entities as symptoms, diseases, drugs and body, (Skeppstedt et al. 2014).

Integrating languages other than English in Apache cTAKES

Apache cTAKES (ctakes.apache.org) has been quite successful in assembling and sustaining a global community of developers and users of state-of-the-art English language clinical NLP. Because these techniques involve computational machine learning methods, datasets from the targeted language are needed to train and evaluate the algorithms on. We will discuss what types and size of data were used to build the various cTAKES components – sentence boundary detector, tokenizer, part of speech tagger, syntactic parser, event and temporal expression detector, temporal relation modules, general relation module. We will also discuss what types of gold standard labels (and how much of each type) are needed to port cTAKES components to other language within the light of some use cases such as porting the temporal expression discovery and normalization module originally developed for English (Bethard, 2013) to Swedish. We will outline available resources in other languages such as Swedish, Finnish, Bulgarian. This is a step towards globalization of information extraction from the clinical narrative.

Panelists

Prof. Hercules Dalianis (Professor at Stockholm University, Sweden) will present on work building on the Stockholm EPR Corpus, a major resource for Swedish clinical NLP.
Dr. Aurélie Névéol (staff scientist at LIMSI-CNRS, France) will act as a moderator and will present the medical and methodological benefits of clinical NLP in languages other than English. Dr. Névéol has been leading a project addressing the automatic understanding of French clinical narratives for translational research.
Dr. Guergana Savova (Assistant Professor at Harvard Medical School) will talk about integrating clinical NLP in different languages. Dr. Savova has been leading the development of the core Clinical Text Analysis and Knowledge Extraction System, now part of the Apache Software Foundation (cTAKES; ctakes.apache.org).
Dr. Pierre Zweigenbaum (principal investigator at LIMSI-CNRS, France) will discuss research efforts for clinical NLP in French, many of which he has initiated and coordinated over the past decade.

List of Discussion Points

After the introductory presentations, the moderator will ask questions as well as solicit questions from the audience, to prompt discussion among the panelists. Potential topics and questions include:
- Describe problems and experiences regarding NLP work on clinical text. How language-dependant is the work you are familiar with? What are the specificities of each language?
- Describe instances of a successful NLP application in a language other than English that yielded interesting new medical knowledge.
- Discuss the methodological challenges to bringing NLP in languages other than English to the level of state-of-the-art for English. Are some specific languages riper than others? Which languages? Why?

- Describe the technical and organizational challenges that must be overcome to integrate several languages other than English in an NLP platform such as cTAKES

The PHR Ignite Project: Advancing Consumer-Mediated Exchange

Stephanie Rizk, MS[1]; Deepthi Rajeev, PhD, MS, MSc[2]; Aaron Seib[3]; Caroline Coy, MPH[4]

[1]RTI International, Research Triangle Park, NC; [2]HealthInsight, Salt Lake City, UT; [3]National Association for Trusted Exchange, Washington, DC; [4] Office of the National Coordinator for Health IT, Washington, DC

Abstract

The growth of electronic health information technology provides new opportunities to actively engage patients in their healthcare. Over the last few years, applications such as personal health records (PHRs) have been widely recognized as instruments to promote patient-centered care and influence patient engagement. Despite advances in health information technology, studies have found that PHRs are not widely adopted across the United States of America. Under funding from the Office of the National Coordinator for Health Information Technology (ONC), RTI International convened partners to support the PHR Ignite project which aimed to study the use of PHRs and their potential to support consumer-mediated exchange. The objectives were to: (a) understand attitudes of consumers towards PHRs, (b) identify features and functionalities of PHRs that may influence adoption among consumers, (c) understand the barriers that discourage the use of PHRs, and (d) explore the use of PHRs to demonstrate the bi-directional exchange between patients and healthcare providers. This panel will present findings and lessons learned during this project and discuss opportunities to improve patient engagement and consumer-mediated exchange.

Personal Health Record Use

The increased adoption of electronic health records and other health information systems offers new opportunities to promote patient–centered care. The promise of using personal health records (PHRs) as instruments that evolve patients from passive witnesses of their health care to engaged partners has been recognized in the literature over the last few years[1]. A true patient-centered PHR would represent a complete patient health care record and allow data sharing across health care settings and systems in a timely manner[2]. However, studies have found that PHRs are yet to be embraced by patients and providers in the United States of America[3]. Several initiatives, including the EHR Incentive program focus on meeting the needs of the patients by leveraging health information technology. For patients to realize the potential of the data now available to them, it is imperative to understand the current landscape of PHR applications in the United States, including existing limitations and barriers that influence adoption and use.

Panel Description

In the summer of 2012, the Office of the National Coordinator for Health Information Technology (ONC) funded the PHR Ignite project managed by RTI International under the State Health Policy Consortium. The project was a collaborative effort between multiple entities to advance understanding related to ONC's three pronged Consumer eHealth strategy: to increase patient access to data, support patients in taking action with that data, and to foster a change in attitudes regarding patient use and interaction with their own data. The members of the panel will describe findings from the PHR Ignite project which supported research to support the increased use of PHRs and their potential to support consumer-mediated exchange. Presenters will cover: a) an assessment of awareness within consumer, provider, and payor stakeholders in Utah and New Mexico and investigation into the factors which support active use of PHR applications, performed by HealthInsight; b) an overview of the technical and governance framework developed by the National Association of Trusted Exchange which supported bi-directional exchange between provider EHR and patient PHR systems in three states using Direct secure messaging. A third panelist from the ONC will discuss the impact of the PHR Ignite project, including a review of a second round of consumer-mediated exchange pilots.

Stephanie Rizk, Health IT Manager in the Center for Advancement of Health IT at RTI International, will serve as the panel moderator. Stephanie served as the assistant project director for the State Health Policy Consortium project and managed the PHR Ignite projects. She will provide a brief overview of the PHR Ignite projects, the projects' objectives, and each project's partners. For the past 10 years, Ms. Rizk has supported projects related to health information technology (health IT) and health information exchange (HIE). She is a skilled facilitator, having led a number of multistate workgroups focused on developing concrete, replicable solutions to interstate exchange challenges. Her areas of expertise include policy and governance related to interoperable HIE, implementation and use of Direct secure messaging for interstate exchange

Deepthi Rajeev, a Medical Informaticist at HealthInsight, was part of the team that assessed the current environment and functionalities of PHRs. She will present findings related to the assessment of attitudes and awareness of stakeholder groups representing consumers, providers, and payors in Utah and New Mexico. She will describe features of PHRs that facilitate in their adoption and illustrate barriers that hinder adoption among patients and providers. She will also present lessons learned from a pilot implementation to explore the use of stand-alone PHRs as a mechanism for consumer-mediated and bi-directional exchange of healthcare data. These findings will reveal the limitations of existing data sharing tools from the perspectives of the patients and providers and help inform the requirements needed to support the meaningful bi-directional exchange of data between patients and providers.

Aaron Seib is CEO of the National Association for Trusted Exchange (NATE), an organization which brings the expertise of state programs together to find common solutions that optimize the appropriate exchange of health information for greater gains in adoption and outcomes. The goal of the NATE PHR pilot project was to enable the wider use of PHRs as a vehicle for patients to bi-directionally exchange data with their providers and inform privacy and security policies as well as operational policies to scale the growth of trusted exchange with patients across the nation.

Caroline Coy is a Program Analyst in the Office of the National Coordinator for Health IT, where she works on adoption of health information exchange. In this role, she has served as a Project Officer for 15 states implementing health information exchanges. Currently, she leads consumer engagement efforts for the HIE program, including a pilot project to demonstrate working examples of consumer-mediated exchange. Caroline will discuss the impact of the PHR Ignite project, including a review of a second round of consumer-mediated exchange pilots.

All proposed panel participants have agreed to take part in the panel.

Discussion Questions

1. What can organizations do to overcome the barriers of PHR adoption and how will they benefit from increased PHR adoption?
2. How do tethered PHRs and untethered PHRs serve patients' needs differently in today's environment?
3. Should efforts to support consumer-mediated exchange focus on the general population or would it be valuable to identify specific patient populations that would most benefit from the use of PHRs?

National Library of Medicine
Bethesda, Maryland

Abstract

Healthcare has benefited from the increasing maturity, availability and implementation of standardized vocabularies. However, many healthcare organizations continue to maintain local terminogies. In doing so, healthcare institutions, individually as well as collectively, expend significant resources on local terminology creation, maintenance and mapping to standardized vocabularies. The purpose of this panel is to describe current approaches to managing both standardized and local terminologies, elucidate challenges and opportunities, and discuss future-oriented strategies for making the process more efficient and effective. The Regenstrief Dictionary, Logical Observation Identifiers Names and Codes (LOINC), Medical Entities Dictionary (MED) at Columbia University Medical Center and the Research Entities Dictionary (RED) at the NIH will serve as case studies. The panel will discuss how a variety of tools, such as the Distributed Terminology System from Apelon, can support local terminology efforts.

After participating in this session, the learner should be better able to:

- describe the major standardized vocabularies for representing content in electronic health records (EHR), and their strengths and weaknesses;
- discuss reasons and approaches for managing local terminologies; and

- describe developments to will make managing standardized vocabularies and local terminologies in a system context easier and more efficient.

General description of panel

Healthcare has benefited from the increasing maturity, availability and implementation of standardized vocabularies, such as the International Classification of Diseases (ICD), the Systematized Nomenclature of Medicine – Clinical Terms (SNOMED CT), Logical Observation Identifiers Names and Codes (LOINC), and RxNorm. Resulting benefits include enhanced interoperability, communication among health care providers, measurability of outcomes and reusability of data for various purposes. The implementation and integration of standardized terminologies into electronic health record systems (EHR) is fairly well-understood and common. Many standards developing organizations (SDO) are using well-structured and formalized processes for updating and maintaining their standards.

However, despite these developments, many healthcare organizations continue to maintain local terminologies. Reasons for this circumstance include the need to represent content not available in standardized terminologies, specific preferences and needs of clinicians, researchers and administrators, and the needs of local communities. In doing so, healthcare institutions, individually as well as collectively, expend significant resources on local terminology creation, maintenance and mapping to standardized vocabularies. The purpose of this panel is to describe current approaches to managing both standardized and local terminologies, elucidate challenges and opportunities, and discuss future-oriented strategies for making the process more efficient and effective. The panel will focus on issues such as:

- How useful and appropriate are major standardized vocabularies for representing content in EHRs? Where do they excel/fall short?
- Why would healthcare institutions need/want to maintain a local terminology?
- How are standardized and local terminologies managed together in the context of commercial EHR systems?
- What are good operational processes for implementing standardized vocabularies and, at the same time, creating/maintaining necessary local terminology/ies to achieve a smooth, integrated whole?
- What tools are available to manage local terminologies? How well do they work? Where do they fall short?
- How can the results of local terminology creation/management processes feed back to the "greater good", e.g. others who are engaged in the same kinds of efforts or standards developing efforts?
- What novel directions, such as crowdsourcing, exist for local terminology management?

Dan Vreeman will describe the history, purpose, and ongoing evolution of the Regenstrief Dictionary. The Regenstrief Dictionary is a homegrown terminology created in 1972 as a core component of the Regenstrief Medical Record System. Now, more than 40 years later, it has given birth to the most widely adopted standard for observations, LOINC, and continues a central role in the operation of the Indiana Network for Patient Care, the country's largest health information exchange. The Regenstrief Dictionary contains 46,000 concepts covering areas such as diseases, drugs, lab tests, nursing orders and survey questions/answers. Many of these terms are linked to standard vocabularies. However, we have become acutely aware of the need to evolve our strategy for managing our terminology needs. Current efforts duplicate much work that already has been done in standard vocabularies. In addition, the software applications

Regenstrief is developing would be more generalizable if they were written on top of standard vocabularies. Dr. Vreeman will present Regenstrief's current strategy for adopting standard terminologies while retaining advantages of local dictionary development. In this context, he will discuss challenges and opportunities for terminology management, personnel resources, needed software tools and collaboration with local healthcare institutions. He will also share lessons learned by "eating what we cook" from Regenstrief's unique role as both an SDO and end user of standard vocabularies.

Mark Tuttle will discuss tools and processes for terminology management, drawing on the example of the NLM Unified Medical Language System (UMLS) Metathesaurus. He will describe Apelon's product and service suite focused on support for local terminology efforts, including the Distributed Terminology System, an open source terminology server. Mark will illustrate terminology development, maintenance and deployment with examples from the National Cancer Institute, the Veterans Health Administration and the Department of Defense. He will review lessons learned from more than two decades of terminology mapping and describe emerging best practices in terminology mapping workflow management.

James Cimino will describe the history, current state, purpose of and strategy to evolve the Medical Entities Dictionary (MED) at Columbia University Medical Center and the Research Entities Dictionary (RED) at the NIH Clinical Center. Each of these is a homegrown terminology that contains the controlled terminologies used by clinical and clinical research systems in their respective organizations. Each consists of an ontological structure that includes a multiple hierarchy, a set of high-level organizing concepts, low-level terms used to code actual patient data, and knowledge concepts to support representation of additional knowledge. Development of the MED was begun in 1988 and includes over 160,000 terms. Development of the RED was begun in 2008 and includes over 280,000 terms. Dr. Cimino will describe how these resources adapt to new terminologies (including standards), remain current with existing terminologies, and support a variety of patient care and research functions.

Why the topic of this panel is timely, urgent, needed and attention grabbing

There is an inherent tension between increasing standardization of content in healthcare and the continuing need for representing local content. As more healthcare institutions adopt standardized vocabularies, their limitations, as well as the limitations inherent in maintaining/evolving them, become more apparent. Standard and local terminology management tend to consume a significant, but largely invisible, amount of resources at healthcare organizations. In an age of increasing cost reduction, institutions are looking for answers to solve this problem.

A list of discussion questions to enhance audience participation

- How many of you represent healthcare delivery organizations? How many of those use ONLY standard terminologies in the EHR?
- How much effort/money do you think you spend on local terminology creation, management and mapping?
- What are your main challenges in managing the implementation of standard and/or local terminologies?

All panelists have agreed to participate on this panel at #AMIA2014.

What's In A Name: Precision Medicine and a New Nosology

Presenters:

Mark S. Tuttle, FACMI, Stuart J. Nelson, MD, FACMI, Yves A. Lussier, MD, FACMI, Funda Meric-Bernstam, MD

Abstract:

In 2012 the National Research Council published a white paper[1] on the need for a new taxonomy of disease, noting the failure of our current disease names to address the needs of precision medicine, based on a deeper understanding of nosology and the requirements of personalized medicine. The panel will discuss the implications of this call in several ways. Dr. Lussier will discuss promising translational bioinformatics innovations in precision therapeutics. Dr. Meric-Bernstam will discuss the importance of finding actionable abnormalities in the genome of the tumors she treats with precision. Dr. Nelson will discuss how this new knowledge can be incorporated into the Bloisian model of disease descriptions[2] as well as how the "classical" patient findings can be used to further develop these descriptions. Mr. Tuttle will discuss the growing experience with supervised and unsupervised machine learning as a tool of discovery, and the application of this paradigm to nosology.

The Call for a New Nosology:

The NRC report explains in considerable depth why current taxonomies of disease are impeding progress. Their "good" example is a patient with breast cancer, including a family history of breast cancer.

> Patient 1 is consulting with her medical oncologist following breast cancer surgery. Twenty-five years ago, the patient's mother had breast cancer, when therapeutic options were few: hormonal suppression or broad-spectrum chemotherapy with significant side effects. Today, Patient 1's physician can suggest a precise regimen of therapeutic options tailored to the molecular characteristics of her cancer, drawn from among multiple therapies that together focus on her particular tumor markers. Moreover, the patient's relatives can undergo testing to assess their individual breast cancer predisposition (Siemens Healthcare Diagnostics Inc. 2008). (p. 9)

Their "bad" example is a patient with Type II Diabetes.

---

[1] National Research Council. *Toward Precision Medicine: Building a Knowledge Network for Biomedical Research and a New Taxonomy of Disease*. Washington, DC: The National Academies Press, 2011. See … http://www.ucsf.edu/sites/default/files/legacy_files/documents/new-taxonomy.pdf AMIA colleagues who contributed to this report include Zak Kohne, Christopher Chute, Dan Masys, and Atul Butte.

[2] Blois, Marsden S. *Information and Medicine: The Nature of Medical Descriptions,* University California Press, Berkeley, 1984.

In contrast, Patient 2 has been diagnosed at age 40 with Type II diabetes, an imprecise category that serves primarily to distinguish his disease from diabetes that typically occurs at younger ages (type I) or during pregnancy (gestational). The diagnosis gives little insight into the specific molecular pathophysiology of the disease and its complications; similarly there is little basis for tailoring treatment to a patient's pathophysiology. The patient's internist will likely prescribe metformin, a drug used for over 50 years and still the most common treatment for type II diabetes in the U.S. No concrete molecular information is available to customize Patient 2's therapy to reduce his risk for kidney failure, blindness or other diabetes-related complications. No tests are available to measure risk of diabetes for his siblings and children. Patient 2 and his family are not yet benefitting from today's explosion of information on the pathophysiology of disease (A.D.A.M. Medical Encyclopedia 2011, Gordon 2011, Kellett 2011) (p. 10)

A central point in their argument is the need for a nosology that is data-driven, and continuously so. Current nosologies are not only inadequate, but their update processes – including the means by which updates are deployed by users – are too slow to keep up with important advances such as those that are part of precision medicine.

The report does not lay out a detailed plan but it does describe many opportunities to improve the naming and classification of diseases. Specifically, it proposes a period of bottom-up innovation constrained only by a desire to share and re-use data.

Stuart Nelson, formerly Head of the MeSH (Medical Subject Headings) Section at the National Library of Medicine (NLM), and lead developer of RxNorm, the current standard for medication terminology in the United States, will lead off with a proposed structure for a new nosology. This structure is based on patient descriptions and builds on the work of Marsden Scott Blois, MD, PhD[3], and is influenced by Dr. Nelson's tenure at the NLM. Simply put, precision medicine will need to be based on more than the diagnostic classes available in currently available taxonomies. As the NRC Report acknowledges, while a major driver behind the need for a new taxonomy of disease is our expanding understanding of molecular foundations, said taxonomy needs to include "incidental patient characteristics, or socio-environmental influences." (p. 14)

Precision Medicine:

While cautionary tales continue to appear[4,5], progress on molecular understanding continues. Specifically, while we're all used to reductionistic science making ever – finer distinctions regarding the structure of the world, occasionally reductionism in

one place – at the molecular level, for instance – can lead to the unified understanding of otherwise disparate events. Yves Lussier, Professor of Medicine and Associate Director of Precision Health and Cancer Informatics at the University of Arizona, and longtime contributor to ontologies supporting translation medicine, will describe an example of such unification, namely how pathophysiologic processes can start in different ways but end up sharing protein synthesis characteristics.

Funda Meric-Bernstam, Chair of Investigational Cancer Therapeutics and Professor of Surgery, at the MD Anderson Cancer Center, will illustrate how a focus on actionable, personal genomics affects the treatment of breast cancer patients. Put differently, her challenge is identify, evaluate and separate the actionable results from interesting, potentially important, but not yet actionable results, as they related to individual patients.

Data Science in Support of Nosology:

Mark Tuttle will address the need to evaluate taxonomies empirically. For example, given two taxonomies ostensibly classifying an overlapping population of patients how can we assess whether one is better than the other? Of course, this implies that we develop evaluative criteria. While, clearly a multi-dimensional challenge, prediction of therapeutic outcome is a unifying theme of this panel. Given this, and related, objectives, one can propose application of – for lack of a better name – the Google paradigm. This paradigm, described by Peter Norvig, Director of Research at Google, can be summarized as follows. First, domain experts "classify" data instances in some previously unclassified, or under-classified, domain, something physicians do already. Second, these classified examples are used as a "training set" during supervised learning of a predictive model. Third, the results of supervised learning are used to initialize unsupervised learning – what used to be called "clustering". Fourth, and finally, an oversight process using ongoing data streams maintains the resulting clusters.

Can such an approach prove useful in healthcare? Can it address some of the objectives of the NRC report? Can it support Dr. Nelson's approach to a new nosology? Can it aid Drs. Lussier and Meric-Bernstam in their effort to leverage emerging results from molecular biology and genomics? These, and related questions, will be left to the audience.[6]

Bourne First Associate Director for Data Science" http://www.nih.gov/news/health/dec2013/od-09.htm "Phil will lead an NIH-wide priority initiative to take better advantage of the exponential growth of biomedical research datasets …" Francis Collins.

Going Digital: Transforming Medical Checklists for Improved Patient Care

Panelists
Bradford Winters, MD, PhD[1], Randall S. Burd, MD, PhD[2], Jesse Cirimele, PhD[3], and, Leslie Wu, BS[3]

Organizer & Moderator
Aleksandra Sarcevic, PhD[4]

[1]Johns Hopkins Medicine, Baltimore, MD; [2]Children's National Medical Center, Washington, DC; [3]Stanford University, Palo Alto, CA; [4]Drexel University, Philadelphia, PA

Abstract

This panel is aimed at addressing the implications and challenges of designing, developing, implementing and evaluating digital checklists in clinical settings. Panelists will share their experiences with checklist design and development, and discuss how digital formats may further improve the impact of the checklist in a range of settings. This is an important panel to have at AMIA in order to engage the community in discussing critical questions about advancing the checklist mechanisms in increasingly digital medical environments. Learning objectives include: (a) formulate an approach for designing digital checklists in a clinical setting; (b) formulate an approach for implementing digital checklist in a clinical setting; and (c) evaluate the effectiveness and impact of digital checklists using both simulated and clinical settings.

General Description

Checklists have become increasingly widespread in health care. Because their use has been associated with a significant decrease in omission errors, death rates, and inpatient complications, checklists are now used across different medical settings, including operating rooms (OR),[1] intensive care units,[2] and anesthesia.[3] An example of an effective use of a medical checklist is the WHO Surgical Safety Checklist, which improves team communication and consistency of care, while markedly reducing complications and deaths associated with surgery.[4]

Most medical checklists used today are paper-based, requiring care providers to manually record the presence or absence of the checklist items. Although paper checklists offer multiple benefits, questions have arisen about their ease of introduction into workflow and their impact on safety; they may complicate tasks, reduce efficiency, and require additional time and attention.[5] While many hospitals continue to use paper checklists, some have started implementing computer-based checklists and interactive cognitive aids to improve patient care and augment user experience.[6] This trend toward checklist digitization does not come as a surprise as medical work has become increasingly digital over the last decade. Similar to paper checklists, however, introducing digital checklists into clinical settings is not simple, and requires consideration of content, format, timing, trial, and feedback, followed by formal testing and evaluation. In addition, clinical settings pose many challenges to designing digital checklists. Checklist design principles taken from the aviation industry have worked well for static, paper-based checklists,[7] but may not be applicable to designing digital checklists for the dynamic and, often more chaotic, medical work.

This panel gathers four researchers and practitioners who have been involved in the design and development of both paper and digital checklists in different clinical settings. Although the work of all panelists focuses on critical care events—surgery, trauma resuscitation and anesthesia crisis—the approaches to designing, implementing and evaluating the checklists are diverse. The four panelists will share experiences in conducting their research and discuss the implications of their studies. These individual stories will then serve as the material for an open discussion with the audience.

Structure & Discussion Topics

The panel session will begin with a ten-minute presentation by the moderator to describe the purpose and format of the panel, and to introduce the panelists. This will be followed by three, 15-minute presentations by panelists detailing experiences, approaches and outcomes of their exemplar studies. We will then open the floor to discussion

among panelists and with the audience in the remaining 35 minutes. Although we expect that topics will emerge through the discussion, some of the topics that may help structure the conversation are as follows:

Design principles & issues: Most medical checklists have been designed based on principles adopted from the aviation industry.[7] These principles, however, may not be applicable to designing digital checklists for the dynamic and, often more chaotic, medical work. Panelists will discuss approaches they used to gather design requirements, as well as overcome design challenges they faced. We also recognize that some systems may be built in house, while some may be commissioned or purchased from a third party. Questions arising here relate to managing and overseeing the design process, and ensuring that the final product meets the user needs.

Implementation issues: Prior research has identified several barriers to the successful implementation of paper-based checklists, including poor communication among team members, lack of leadership, inappropriate timing for checking an item, and time taken up by checklist completion.[5] Do the same barriers apply to implementing digital checklists? What are the issues we need to consider when implementing digital checklists?

Evaluation issues: Evaluating the impact and effectiveness of checklists is an important aspect in checklist design. Panel members have extensive experience in testing and evaluating both paper and digital checklists in simulated and clinical settings. We will discuss how to design evaluation studies for digital checklists, obtain human subjects protection approvals, collect data, and define evaluation metrics.

Anticipated Audience & Importance of the Topic

This panel session will be of interest to all AMIA members, and particularly to healthcare providers and informatics professionals working in critical care settings. This is a timely topic to discuss given the widespread use of medical checklists and the trend toward digitization of medical care. The panel will educate about the implications and challenges associated with designing, developing, implementing and evaluating digital checklists in a range of clinical settings. Panel members will synthesize their perspectives on these issues and likely future developments in this area, exploring a diverse set of topics and engaging in thoughtful discussion with the audience.

Brief Description of Panelists & Presentations

Bradford Winters, MD, **PhD** is an Intensivist and Anesthesiologist at the Johns Hopkins Hospital and a Core Faculty member of the Armstrong Institute for Patient Safety and Quality at the Johns Hopkins University School of Medicine. His research interests include reducing patient harm through the implementation of Rapid Response Systems, applying broader modalities for patient monitoring and the use of cognitive tools such as checklists and technological solutions to reduce patient harm and adverse events.

Dr. Winters will present a framework for checklist development, and discuss the development and implementation of checklists in the Intensive Care Unit (ICU) environment to improve safety and reduce gaps in the quality of care, including reduction in hospital acquired infections, improved mechanical ventilator care, and appropriate deep vein thrombosis prophylaxis. He will discuss the challenges of implementing and especially digitizing such cognitive tools into the workflow of the ICU.

Randall S. Burd, MD, PhD is the Division Chief of Emergency Trauma and Burn Services and a pediatric surgeon at Children's National Medical Center in Washington, DC. His research interests are in pediatric trauma, with a particular focus on prehospital prediction of severe injury and emergency department resuscitation. Over the past eight years, Dr. Burd has directed a multidisciplinary team that is developing new analytic and technological approaches for rapidly identifying severely injured children, and providing them with safe and efficient care in the emergency department. His currently-funded research has given him expertise in directing the clinical development and assessment of new technologies to support teamwork during resuscitation, designing and implementing simulation for assessment of new technologies, and analyzing the information needs of resuscitation teams.

Dr. Burd will present his recent work on the checklist development for trauma resuscitation. Adverse outcomes in this domain have been associated with omission of key steps in the initial management of injured patients despite continued simulation training and didactic teaching. Dr. Burd and his research group have developed a checklist for trauma resuscitation that improves compliance within this process. Dr. Burd will discuss the approach they used to develop and evaluate this checklist in both simulated and clinical settings. He will also discuss how the checklist impacts communication patterns and potential ways in which a digital format may further improve the checklist's impact in this setting. Finally, Dr. Burd will present how they used digital pen technology to inform the design of a digital checklist, using an approach that allows analysis of the accuracy and timeliness of checkbox completion.

Jesse Cirimele, PhD is a Postdoctoral scholar between the Computer Science Department and the Medical School at Stanford University. He received his PhD in Computer Science from Stanford University with a focus on human-computer interaction. Dr. Cirimele has Bachelors degrees in Cognitive Science and Mathematics from University of California, San Diego. His research has looked into decision support in critical care, adaptive mobile interfaces, mobile health interventions, and improved browser history interfaces.

Leslie Wu, BS is a PhD candidate in Computer Science at Stanford University with a focus on human-computer interaction. Leslie has a BS in Computer Science from the University of Illinois at Urbana-Champaign. Her previous research has investigated web service development and on-demand techniques for data integration and visualization. She has worked on several mobile health startups and is interested in applying crowdsourcing and mobile applications and technology to improving healthcare systems.

Jesse Cirimele and Leslie Wu will co-present their joint work on Dynamic Procedure Aids, an approach for addressing four key problems in the use of medical checklists: ready access to the aids, rapid assimilation of their content, professional acceptance of their use in medical procedures, and limited attention available to their users. To understand the efficacy of Dynamic Procedure Aids for crisis response, Jesse and Leslie created dpAid, a software system for crisis medicine. dpAid's design was based on a year-long observational study of medical teams responding to simulated crises. dpAid was deployed on tablets and large-screen displays, and evaluated in simulated medical crises using eye-tracking hardware.

Aleksandra Sarcevic, PhD is an Assistant Professor of Informatics in the College of Computing and Informatics at Drexel University. Her research interests are in computer supported cooperative work and medical informatics, with a focus on ethnographic studies of work practices and interface design for safety-critical medical settings. Her recent work is in the area of emergency medical resuscitations, where she hopes to reduce human errors and increase teamwork efficiency by introducing a series of technological interventions. She was awarded a 2013 National Science Foundation Early CAREER Grant to continue her work on information technology design for fast-response medical teams.

Dr. Sarcevic will moderate the panel.

Participation statement: All proposed panelists have agreed to participate in the panel.

Evolving Career Landscapes in Biomedical and Health Informatics

Rui Zhang, PhD[1,2], William Hersh, MD[3,4], Genevieve B. Melton, MD, MA[1,2], Yang Huang, PhD, MSCS[5], Laura Wiley, MS[6], Julie Doberne[3], Nawanan Theera-Ampornpunt, MD, PhD[7]

Abstract

The career landscape for biomedical and health informatics students continues to expand. With the recent successful administration of the first Clinical Informatics Subspecialty Board Exam and trends in the fields such as healthcare data analytics, the informatics workforce must be well-prepared for diverse career opportunities and a changing healthcare landscape. Following tradition, the AMIA Student Working Group proposes a "career panel" to offer perspectives and advice for students on the success of their career opportunities and professional development. This year, panelists include an academic program director, hospital chief medical informatics officer (CMIO), and industry Research and Development (R&D) director, each with different training backgrounds (e.g., MD, PhD, MA). They will share their experiences and discuss upcoming trends in informatics careers with students. This panel will help current informatics students and early-career professionals to better prepare for and develop their careers.

General Description

Since 2002, the American Medical Informatics Association (AMIA) Student Working Group (ST-WG) has organized a panel during the AMIA annual symposium each fall to provide perspectives and advice on career development for current informatics students, recent graduates and early-career professionals. The career panel has become a valuable component of the symposium for the students and other attendees to actively interact with successful informaticians.

The career opportunities in the field of informatics are growing exponentially due to clinician and researcher needs for biomedical and health information, as well as the continued adoption of health information technology in clinical practice. In 2013, the first group of physician-informaticians passed the first *American Board of Preventive Medicine Clinical Informatics Subspecialty Board Exam*. These board-certified professionals are only the first of many more to come, and AMIA has additional planning underway to develop certification pathways for other informatics professionals besides physicians. In this exciting age, career development advice is more important than ever. Last year's career panel featured panelists from academia and industry with clinical and technical backgrounds. This panel attracted over one hundred attendees and raised many interesting questions.

This year we not only build on this successful tradition but also enhance it in the following ways. This panel will

(a) Feature panelists who are involved in the Board Exam, providing perspectives and helpful advice for professionals;
(b) Give an overview of the entire workforce of informatics professionals (not limited to clinicians);
(c) Discuss current shift in focus from implementation to analytics;
(d) Provide suggestions for different degree levels of informatics, including MD, PhD, and Masters students; and
(e) Share experiences of various career paths: faculty, Chief Medical Information Officer (CMIO), and research directorship.

The planned format is the traditional panel discussion. Each of the panelists is allotted 15 minutes for a short presentation followed by 5 minutes of questions. After 10 minutes for closing discussion, there is a 30-minute session to increase audience participation, with a list of questions.

1) Which experience or factors played a key role in your informatics career?

2) What are the expectations for professional, PhD, and master students, both in academia and industry?
3) What are the differences in career paths for professional, doctoral and master students?
4) How should students prepare and ready themselves for the coming career opportunities and trends?
5) How should early career informatics graduates continue to improve skills and achieve success in their careers?
6) What level of programming knowledge should an "informatics expert" have, clinicians or non-clinicians?

Given the different career experiences and educational backgrounds of the panelists, this panel will provide valuable perspectives for professional, PhD and master's students, who are studying, looking for jobs or just entering the field and beginning to develop their careers in informatics. By the end of the panel, attendees should be able to:

1) Gain familiarity with the clinical informatics board certification;
2) Gain a sense of the multitude of career paths in biomedical informatics;
3) Understand current trends in the biomedical informatics field;
4) Understand the goals and pathways for various degree levels (MD, PhD, Masters, etc.)

Statement

It is confirmed that all panelists listed in this proposal have agreed to participate in this panel. Panelists are aware that there are no travel or registration funds available. Panelists are also aware that the Student Working Group is unable to reimburse their registration costs.

Panel Title:

Technology transfer from biomedical research to clinical practice: measuring innovation performance

Abstract

Background Earlier studies documented 17 years of transfer time from clinical trials to practice of care. Launched in 2002, the NIH translational research initiative needs to develop metrics for impact assessment. A recent White House report highlighted that R&D productivity is declining as a result of increased research spending while the new drugs output is flat.

Goals To support measurement and improvement, this study developed an expanded model of research based innovation and identified performance thresholds of technology transfer from research to practice.

Methods A wide range of models for transfer of research to practice have been collected and reviewed. Subsequently, clusters of models have been created based on common characteristics. Additionally, measures of research transfer were reviewed based on nationally available data. Milestones of progress have been identified based on the 2012 AUTM performance reports.

Results An integrated, Intellectual Property Transfer (IPT) model is described. The central but often disregarded role of research innovation disclosure is highlighted. Numeric milestones of technology transfer are recommended at threshold (top 50%), target (top 25%) and stretch goal (top 10%) performance levels. Measures and corresponding target levels include research spending to disclosure (<$1.88M), disclosure to patents (>0.81), patents to start-up (>0.1), patents to licenses (>2.25) and average per license income (>$48,000). Several limitations of measurement are described.

Conclusions Academic institutions should take strategic steps to bring innovation to the center of scholarly discussions. Technology transfer regulations must be transparent and must support researchers and institutions needs in the innovation to practice cycle (IPC). Research on research, particularly on pathways to disclosures, is needed to improve R&D productivity. Researchers should be informed about the technology transfer performance of their institution.

Panel Members:

Dr. Balas and Dr. Elkin recently published:

Technology transfer from biomedical research to clinical practice: measuring innovation performance. Balas EA, Elkin PL. Eval Health Prof. 2013 Dec;36(4):505-17.

E. Andrew Balas, MD, PhD

Andrew Balas serves as Dean and Professor at Georgia Regents University. His expertise includes development of priorities for the production of innovative scientific knowledge responsive to societal needs and application of advanced digital technologies for transferring research to practice.

He is member of the Board of Directors of the Friends of the National Library of Medicine and also the Allied Health Research Institute. He is an elected member of the American College of Medical Informatics and the European Academy of Sciences and Arts.

Andrew Balas has been effective in taking on the status quo, achieving breakthrough performance improvements and fighting for better public access to scientific discoveries. His studies about delay and waste in the transfer of research results to health care are often cited as reference points in translational research initiatives. As a Congressional Fellow working for the Public Health and Safety Subcommittee of the United States Senate, he drafted the Healthcare Quality Enhancement Act of 1999 that, among others, first achieved government action on reducing errors in health care and was signed into federal law (Dec. 6, 1999).

His leadership emphasizes positive response to community needs, teamwork and measurable improvement. During six years of his previous service as Dean, the College of Health Sciences achieved many successes at Old Dominion University in Norfolk, Virginia (e.g., double digit increases in enrollment, solid accreditations, launching of new programs, tenfold increase in externally funded research; multimillion dollar fundraising, new R&D partnerships with industry). Previously, he served as Dean of the School of Public Health in St. Louis, Director of the Missouri European Union Center and Weil Distinguished Professor of Health Policy at the University of Missouri.

His academic credentials include over 100 publications, externally funded research in excess of 10 million dollar and publications that cumulatively attracted thousands of citations. He obtained degrees in medicine, medical informatics (Ph.D.), and applied mathematics.

Peter L. Elkin, MD, MACP, FACMI, FNYAM

Dr. Elkin serves as Professor and Chair of the UB Department of Biomedical Informatics. He is also a Professor of Medicine at the University at Buffalo. Dr. Peter L. Elkin has served as a tenured Professor of Medicine at the Mount Sinai School of Medicine. In this capacity he was the Center Director of Biomedical Informatics, Vice-Chairman of the Department of Internal Medicine and the Vice-President of Mount Sinai hospital for Biomedical and Translational Informatics. Dr. Elkin has published over 120 peer reviewed publications. He received his Bachelors of Science from Union College and his M.D. from New York Medical College. He did his Internal Medicine residency at the Lahey Clinic and his NIH/NLM sponsored fellowship in Medical Informatics at Harvard Medical School and the Massachusetts General Hospital. Dr. Elkin has been working in Biomedical Informatics since 1981 and has been actively researching health data representation since 1987. He is the primary author of the American National Standards Institute's (ANSI) national standard on Quality Indicators for Controlled Health Vocabularies ASTM E2087, which has also been approved by ISO TC 215 as a Technical Specification (TS17117). He has chaired Health and Human Service's HITSP Technical Committee on Population Health. Dr. Elkin served as the co-chair of the AHIC Transition Planning Group. Dr. Elkin is a Master of the American College of Physicians and a Fellow of the American College of Medical Informatics. Dr. Elkin chairs the International Medical Informatics Associations Working Group on Human Factors Engineering for Health Informatics. Dr. Elkin is the Editor of the Springer Informatics Textbook, Terminology and Terminological Systems. He was awarded the Mayo Department of Medicine's Laureate Award for 2005. Dr. Elkin is the index recipient of the Homer R. Warner award for outstanding contribution to the field of Medical Informatics.

Ross Koppel, PhD

Dr. Koppel is a Professor of Sociology at the University of Pennsylvania who is world renowned for his identification of unintended consequences of Health IT. He has published widely, is a dynamic speaker and is a strong advocate for safer healthcare through the appropriate implementation of tested technologies. He joins the panel to discuss quality in Informatics applications development and implementation. He has published numerous high impact articles and is a fellow of ACMI.

Patient health records (PHRs), patient access to their records/medical information: issues and challenges

Abstract

The AMIA ClS, ELSI, EVAL, and POI Working Groups, with collaboration from the Society for Participatory Medicine (SPM), propose an interactive panel to address issues and challenges regarding PHRs and patient access to their records and medical information. Four panelists will address the topic from their varied experiences and expertise as informaticists, clinicians, clinical staff, and an healthcare attorney. Rather than include a single panelist to represent the patient point of view, we have invited five engaged patients from SPM to participate in the audience, comment, ask questions, and react to and interact with the panelists and other audience members.

Introduction

The AMIA ClS, ELSI, EVAL, and POI Working Groups, with collaboration from the Society for Participatory Medicine (SPM), propose an interactive panel to address issues and challenges regarding PHRs and patient access to their records and medical information, which involve the complex and sometimes competing interests and needs of many stakeholders. Patient access to their medical information and engagement in their care through HIT is a critical topic because it is an objective of Meaningful Use (MU). Four panelists will address the topic from their varied experiences and expertise as informaticists, clinicians, clinical staff, and an healthcare attorney. Rather than include a single panelist to represent the patient point of view, we have invited five engaged patients from SPM to participate in the audience, comment, ask questions, and react to and interact with the panelists and other audience members. The moderator will introduce them as audience-participants and ensure that they and our more traditional participants have ample time for interaction with each other and our panelists. Each presenter will take 8 minutes to discuss questions/points from those posed below, and as a springboard for discussion, take a position on what is most crucial to happen to achieve the following goals: optimum patient engagement, the most productive patient-provider relationships, and improved outcomes and satisfaction. The objective for the intended audience -- all interested members and patients -- is to gain understanding from many perspectives, and despite varying interests, needs, and existing and ongoing challenges, find ways to collaborate to achieve these mutually beneficial goals.

1) How can access to medical records be improved and are PHRs and electronic delivery the best or only (de facto) option for empowered patient engagement (e.g. How far down the PHR push are we? What about socioeconomic disparities that pose barriers to computer access; varying patient literacy/numeracy; patient preferences re level of engagement and electronic format?)
2) How can PHRs/portals be used to successfully engage patients in their own care -- what do and don't patients want, need, what concerns them, and how do we know? (e.g. Will electronic forms of patient engagement improve outcomes, or might they perpetuate or exacerbate health disparities - how will we all know?)
3) What are clinician concerns regarding PHRs and patient access to their medical information? (e.g. Ethical, legal, impact +/- on patient-clinician relationship, workflow issues, clinical team communication, etc.)
4) What are institutional, regulatory, and legal concerns/issues (e.g. Operational, required resources, technology options, HIPAA, Meaningful Use, what information can, should or must be kept out of medical records)?
5) How can the comprehensibility and actionability of medical data be improved?
6) What are key areas related to PHRs and access that need to be evaluated, and what evaluation methods will be needed to assess the effects of patient access to medical records and portals?

Panel members (All listed panel members and engaged-patient participants have agreed to participate.)

1) Catherine K. Craven, MLS, MA (Panel Organizer and Moderator), Chair, EVAL WG, is a doctoral candidate in Health (clinical) Informatics and a past NLM Informatics Fellow at the MU Informatics Institute, University of Missouri, Columbia, Missouri, USA. Her research covers implementation processes in small, rural Critical Access Hospitals; technology impact on ICU clinical team communication; and she is a member of Univ. of Missouri's CMS Health Care Innovations Challenge award team to leverage HIT to improve primary care coordination and patient engagement for better patient and population health, improved care, and cost outcomes.

2) Joseph Kannry, MD, Chair, CIS WG, is Professor of Medicine, a practicing board-certified Internist, and Lead Technical Informaticist for the Mount Sinai Health System, New York, New York, USA. In 2004, he led Mount Sinai's Ambulatory EMR Selection. Since 2005, he has been the Lead Technical Informaticist for the EMR Clinical Transformation Group. He oversees Ambulatory EMR implementation for the Hospital Based Practices and Faculty Practice Associates, PHR implementation, Enterprise CDS, and assisted with Inpatient implementation. Mount Sinai received the 2013 Davies Award for Enterprise EHR.

3) Jessica Ancker, MPH, PhD, Chair-elect, EVAL WG, Assistant Professor at Weill Cornell Medical College, New York, New York, USA, studies evaluation challenges in HIT, numeracy and decision-making issues among patients and providers, and has published on patient portal use among underserved populations. She is the recipient of an AHRQ K award to study patient portals and patient information needs.

4) Paul R. DeMuro, CPA, MBA (Finance), MBI, JD, FHFMA, FACMPE, CHC, is Co-Chair, Healthcare Information & Technology Group, Schwabe, Williamson & Wyatt, and an NLM Post-Doctoral Fellow in the Biomedical Informatics PhD program, Clinical Informatics, Dept. of Medical Informatics and Clinical Epidemiology, School of Medicine, OHSU, Portland, Oregon, USA. With 35 years of health law experience, Paul is a legal architect who develops clinically integrated models with aligned incentives using informatics technologies. Patient access to medical information is a key component of such models.

5) Carolyn Petersen, Chair, ELSI WG, is a Patient Advocate for NCI's Cancer Bioinformatics Grid since 2009, a Consumer Representative to FDA advisory panels since 2002, a Patient Stakeholder Reviewer for PCORI (Advancing Research Methods area) since they started making awards in 2012, and a managing editor of Mayo Clinic's (Rochester, Minnesota, USA) internationally renowned Web site since 2000. She's been a survivor of a pediatric cancer for more than 30 years, a driving reason for her career path and her advocacy work.

Engaged-patient audience participants from the Society for Participatory Medicine

1) Donna Cryer, JD, is an engaged patient herself as an IBD and liver transplant patient. Among many advocacy activities, she serves as a patient representative to the U.S. FDA, a merit reviewer for the Patient Centered Outcomes Research Institute (PCORI), and a member of the Stakeholder Advisory Group to the NIH Learning Health System Research Collaboratory. Most recently, Donna served as Chair, President, and CEO of the American Liver Foundation, the first patient to lead the organization in its 36-year history.

2) Gayle Embt, was caregiver for a parent with Alzheimers and multiple chronic conditions and is a caregiver for a child with complex needs, including pediatric mental health issues. She lives with the impact that the lack of understood expectations, technology enabled communications, and consistency of data sharing, has on the quality and accuracy of the care being delivered. Gayle co-chairs the Patient Experience Council at the Sullivan Institute for healthcare Innovation, served as a caregiver reviewer on the 2013 WEDI roadmap for data exchange.

3) Kym Martin, MBA, CNC, CFT, is an engaged patient as a 30-year, three-time cancer survivor. She is an appointed Co-Chair of the Patient Experience Council affiliated with The Sullivan Institute for Healthcare Innovation and Workgroup for Electronic Data Interchange (WEDI). Her major advocacy effort revolves around the need to shift focus to the overall patient *experience* as a key pathway to sustainable patient engagement.

4) Anna McCollister-Slipp builds platforms for better understanding of and engagement with the needs of patients, which is rooted in her personal experiences living with type 1 diabetes for 28 years. Anna was a member of the ONC HIT Policy Committee's FDASIA Workgroup, charged with advising the government on a regulatory pathway for HIT that would protect patients and promote innovation. As a co-founder of Calileo Analytics, she was named a "Woman to Watch" at Health Datapalooza and was invited to participate in "The Hive" at TEDMED 2013.

5) Mary Anne Sterling has 18 years of experience as a healthcare navigator for aging parents; three of her and her husband's parents suffer from or have died of forms of dementia. Among many engaged caregiver activities, Mary Anne serves on the ONC HIT Policy Committee's Consumer Empowerment Workgroup, and is Alzheimer's Association Ambassador to Sen. Mark Warner's office for implementation of the National Alzheimer's Project Act.

Brief description of panelist presentations

J. Kannry: Will start with what is a PHR, the difference between tethered vs. non-tethered PHRs, and discuss, via key studies, why this matters in the context of Meaningful Use (MU). He will review how MU Stage 2 and beyond has outstripped the evidence in the peer-reviewed literature [1, 2] Because MU is a huge driver of patient engagement through HIT, which is one of 6 listed objectives of the entire MU program, he will address the following questions: 1) Do we have any Informatics evidence that supports meaningfully used PHRs? [3-5]; 2) Based on this evidence, what do we know about patient needs and wants?; 3) What does evidence say about clinician wants, needs, and concerns regarding PHRs? He'll discuss challenges for the commercial market,

institutional, provider and patient challenges, and explore what an ideal PHR might look like.

J. Ancker: Will highlight current literature about the prevalence and use of electronic patient portals and PHRs [6-7] and their efficacy and effectiveness for improving outcomes and behavior [8-9]. She will discuss disparities in usage on the basis of socioeconomic predictors and implications for their impact, and place these technologies in context of health behavior theories to suggest future directions for practice and research.

P. DeMuro: There is much discussion over who owns the medical record and medical information. [10] The US and other countries often have contrasting views, and whether the answer differs for medical records vs. PHRs. This section also will address what a patient can access, view, copy, and amend in his or her medical record [11], and what types of information can be kept out of the medical record, given the HITECH Act, for example, state law considerations and psychotherapy notes. [12] How one can get as much of his or her EHR as possible will be discussed, along with how components of an EHR provided to others might be monitored and/or tracked. [13]

C. Petersen: To be most effective, engagement efforts must meet patients "where they live" via technologies and approaches they will readily use to access care and manage their health. [14, 15] Patient portals are one approach but require patients to possess technical competency, language and health literacy skills, access to technology, and stability in living situation. [16,17] Many patients who would gain most from a stable, engaged relationship with healthcare providers (e.g., Medicare/Medicaid patients, people with cognitive/physical disabilities) are unable to experience the full benefit of such relationships. [18] This segment will discuss benefits and challenges associated with patient portal use and other patient-engagement approaches from the perspective of the patient, as well as technologies and approaches proven to facilitate effective patient engagement, e.g. patient portal, mobile phone interventions, and social media. Expectations as expressed by patients and in the literature will be presented.

Nursing Data to Support the C-CDA, eMeasures, and Big Data Science - Ready or Not?

Connie W. Delaney, PhD, RN, FAAN, FACMI[1]; Gay Dolin, MS, RN[2]; Susan A. Matney, MSN, RN, PhD-C, FAAN[3]; Judith Warren, PhD, PhD, RN, FAAN, FACMI[4]; Bonnie L. Westra, PhD, RN, FAAN, FACMI[1]

[1]University of Minnesota, School of Nursing; [2]Intelligent Medical Objects; [3]3MHealth Information Systems; [4]Warren Associates, LLC

Abstract

Standardization of data and data structures are essential for sharable and comparable data to support the Consolidated Clinical Document Architecture (C-CDA), development of eMeasures (quality measure from electronic health records (EHRs)) for meaningful use of EHRs, and reuse of the data for big data science. Data standards and eMeasures are prescribed by the Federal government – LOINC for Assessments, and SNOMED-CT for nursing problems and interventions. Nursing has a long history of terminology development and mapping of nursing terminologies. This panel addresses the urgency of assuring that nursing data is ready to support these efforts and to learn strategies form the audience to rapidly propel standardization of data and data structures to support national efforts.

Introduction

Under the Health Information Technology for Economic and Clinical Health (HITECH) Act, the Office of the National Coordinator (ONC) and the Centers for Medicare and Medicaid Services (CMS) provide funds to increase the use of EHRs and require providers and hospitals to meet meaningful use of the EHR criteria. The Health Information Technology Policy Committee developed recommendations on the assignment of code sets to clinical concepts [data elements] for use in quality measures. Data must be extracted from EHRs as defined by the Quality Data Model (QDM) and expressed with the eMeasure format (AKA the Health Quality Measures Format (HQMF)). The results must be reported in the Quality Reporting Document Architecture (QRDA) I or III. The QRDA I leverages the templates in C-CDA and adds further requirements necessary for expressing Clinical Quality Measures (CQM) data. To support continuity of care, EHR technology must be able to electronically receive transition of care/referral summaries in accordance with the Consolidated Clinical Document Architecture (C-CDA). Simultaneously, to achieve the triple aim of better care, health and efficiencies in care delivery, there is an increasing emphasis on interprofessional practice that patient-centered and uses evidence-based practice (EBP) guidelines. Structured and standardized EHR is foundational to evaluate outcomes of care as well as discover new knowledge through comparative effective effectiveness research.

The American Nurses Association has recognized 12 terminologies and data sets; however, the HITECH requirements for the C-CDA and eMeasures requires data to be stored as Logical Observation Identifiers Names and Codes (LOINC) codes for assessment tools and Systemized Nomenclature of Medicine Clinical Terms (SNOMED CT) codes for nursing problems, clinical findings, and procedures (interventions) The major issue is whether nursing is ready to share data via the C-CDA and demonstrate quality with eMeasures using these standards. This panel addresses the urgency of assuring that nursing data is ready to support these efforts and to learn strategies form the audience to rapidly propel standardization of data and data structures to support national efforts.

Objectives

This panel will provide brief presentations and engage the audience in discussion to:

1. Describe the drivers for standardization of nursing and other health professional's data.
2. Explore the relationship of standardized nursing data to the C-CDA and specifically the Care Plan.
3. Relate the requirements for nursing data for eMeasures.
4. Examine initial efforts to create a nursing problem list to compliment the Core Problem list of meaningful use of EHRs using SNOMED-CT to bridge disparate nursing terminologiesl
5. Discuss the current status of nursing assessments included in LOINC
6. Contribute to an action plan to propel use of standardized nursing terminologies to support federal requirements to achieve the triple aim.

Moderator: Connie W. Delaney, PhD, RN, FAAN, FACMI

Dr. Delaney will provide a brief overview of national efforts that demonstrate the need for standardized data and data structures. She will address the synergy of the "Big Data" agenda that includes the Clinical

Translational Science Awards (CTSA) funded by the National Center for Advancing Translational Sciences (NCATS), National Institutes of Health, the Patient Center Outcomes Research Institute (PCORI) goals, the National Center for Interprofessional Practice & Education, and how this synergy relates to standardization of nursing data and structures to achieve the Triple Aim.

Question(s):

As this synergy and integration occurs, what transformation of scientist training must occur?

1. Will knowledge representation of our interprofessional practice be accommodated by disciplinary specific representations?
2. What implications does the integration have for EHR design?
3. As this synergy and integration occurs, what transformation of scientist training must occur?
4. How will the practice models change?

eMeasure Development: Judith J. Warren, PhD, RN, FAAN, FACMI

The evolution of quality indicators, manually extracted to eMeasures electronically extracted, reveals issues concerning the implementation of data standards and the need for data integrity. The challenge is that every hospital has implemented their own documentation system so that data queried from one hospital is not in the same format, or even data type, as another hospital, and thus not comparable. Furthermore, not all implemented EHRs use the ONC/CMS mandated terminologies. eMeasure developers must identify data elements that capture the essence of the quality indicator without a human involvement to validate the comparability of the clinical data. Second, many members of the health care team document on the same data elements. When these do not coincide, the source of truth needs to be identified for the query. Below are a series of questions that are generated as eMeasures are developed and tested by one quality indicator developer.

Question(s):

1. What must be in place to have semantic interoperability? How can data standards facilitate the extraction and comparison of clinical data across clinical sites?
2. If terminology standards and maps are established, where would they be posted for all to use? Do we need agreed upon approaches to turn evidence-based practice protocols into data collection strategies? Who would do this?
3. How is the logic developed to generate the indicator? If anyone, who should endorse the logic set?
4. Where should maps and the logic set for eMeasure be posted to increase consistency?
5. How would eMeasures be collected: queries, clinical decision support rules, or another innovative strategy? How would the eMeasure data be processed and used in benchmarking—do we need quality indicator developers to do this or another type of vendor?
6. Then how do we know that the data extracted by the queries is correct and has integrity? As you look at data pulled from a query, you don't always see what is expected. Data is charted in the wrong place or put in a comment (thus unseen by a query).

Standardized Data Requirements for the C-CDA: Gay Dolin, MSN, RN

Gay Dolin will present a brief overview of the new Care Plan document type in C-CDA R2 focusing on how the HL7 CDA model together with standardized vocabularies, very effectively express the relationship between Care Plan components. A diagram will be shown to demonstrate the components of a Care Plan and the flow between them as expressed by HL7 CDA model. We will discuss how, through the syntax provided by the HL7 CDA model, refined though templates in the C-CDA R2 Care Plan, together with the semantics provided by controlled vocabularies, can fully express not only the requirements of a nursing Care Plan, but also a complete instance of an interdisciplinary patient centered care plan at a point in time.

Question(s):

1. The importance of syntax to fully express a concept using standardized vocabulary. E.g. The observation, diagnosis, intervention was made by who in what role.
2. A Care Plan is a living, changing plan. A CDA instance is a static expression of that plan. What is the value of this?

SNOMED CT Nursing Problem List: Susan Matney, RN-BC, MS, PhD-C, FAAN

The problem list is a key component of patient care and has been acknowledged as critical by the EHR Meaningful Use criteria. Specifically, SNOMED CT has been mandated as the terminology to use when storing

coded problems in the problem observation section of the C-CDA. Nursing diagnoses (problems) on the problem list are foundational for constructing a comprehensive care plan. A multidisciplinary patient problem list will facilitate communication and evaluation of the contribution of nursing care to the patient's clinical care experiences and outcomes. A nursing problem list subset of SNOMED CT has been developed by examining cross mappings between SNOMED CT and other nursing terminologies. The subset contains a complete list of all SNOMED CT concepts relevant for nurses to code a nursing diagnosis, is freely available from the National Library of Medicine website. Making use of this subset will decrease terminology development effort, reduce inconsistency and facilitate sharing of problem list data. A process for ongoing maintenance and continued work with UMLS in mapping nursing diagnoses concepts to SNOMED CT is in place to ensure that all ongoing concepts are proposed to address this limitation in future nursing problem subsets.

Question(s):

1. What is the current state of using the SNOMED CT problem list for exchange of data across multiple nursing terminologies?
2. What actions are needed to continue the development of SNOMED to fully represent the domain of nursing?

Nursing Assessments in LOINC: Bonnie L. Westra, PhD, RN, FAAN, FACMI

LOINC is typically considered a standardized coding system for laboratory data, however, it also include other domains such as document names, nursing management data, and clinical assessments as well as outcome ratings. LOINC includes coded assessment data as single measures such as blood pressure as well as panels and surveys such as vital signs, the Braden Scale, or the Minimum Data Set used in nursing homes. To evaluate the coverage of nursing assessments, a "gold standard" is required to both determine what assessments are in LOINC and the additional assessments that are needed. A brief overview of this project will be presented and participants will be asked about strategies to assure adequate coverage of assessments.

Question(s):

1. What should be the "gold standard" to determine coverage of assessments for inclusion in LOINC?
2. How should assessments be organized to assure consistent coding across settings, vendors, and EHRs?
3. What resources are needed and available to support collaboration in order to expedite the work needed?

Conclusion

Standardization of nursing and other health professional terms are essential as well as the models for reuse of the data for quality and research. Progress has occurred over the past 40 years, but further work is needed. The discussion from the audience will provide additional insights to propel this work forward in the future.

HIE Enablers: A Crucial Need for Care Coordination Communication Among Long-Term and Post-Acute Care Front Line Nursing and Other Staff

Jennie Harvell (Moderator)[1], Gregory L. Alexander PhD, RN, FAAN,[2] Colene M. Byrne, PhD[3], Michelle Dougherty, MA, RHIA[4]

[1]U.S. Department of Health & Human Services Office of the Assistant Secretary for Planning and Evaluation, Washington, DC [2]University of Missouri, Sinclair School of Nursing, Columbia, MO; [3]Westat, Cambridge, MA; [4]AHIMA Foundation, Chicago, IL

Statement of Participation: All presenters have participated in development of this proposal. All have confirmed their participation in this panel presentation should it be accepted.

Abstract

We propose a panel to explore and discuss the current conditions and enablers to support care coordination including transitions in Long-Term and Post-Acute Care (LTPAC). Our four expert panelists will provide position statements, based on their experience in current research and initiatives, about the state of HIT adoption and use of Health information exchange (HIE) to support LTPAC coordination. We will discuss policy levers that enable HIE, as well as barriers, such as the lagging HIT adoption by LTPAC providers and the status of HIE interoperability standards to support LTPAC. Our positions are grounded in important themes of Technology, Adoption, Communication, and Workflow, specific to LTPAC settings. A learning objective for persons participating in this panel discussion is to present a real-world view of LTPAC HIT and HIE adoption, and interactively explore opportunities to advance HIE with LTPAC providers, as senders and receivers of key patient information.

Intended Audience

The intended audience will cover a range of disciplines, including LTPAC staff, telehealth providers, health care administration, clinicians with knowledge of Health IT, Chief Medical Officers, Chief Medical Information Officers, Chief Nursing Information Officers, researchers (e.g., health IT, telehealth, home health, nursing home), and nurse informaticists. Some audience members may not have deep knowledge of LTPAC and HIE opportunities. Through panel discussions they will gain new knowledge about opportunities to support HIT and HIE adoption in LTPAC.

Introduction of the Topic

LTPAC providers play an important role in the U.S. healthcare system, providing care for 1.5 million frail elders. Over a third of all Medicare patients discharged from hospitals receive subsequent LTPAC services[1]. Annual costs for LTPAC services in the U.S. have reached over $200 billion, with 69% being paid by Medicare and Medicaid[2]. As the U.S. population ages, persons 65 and older are expected to triple to 1.5 billion by mid-century, the demand for LTPAC services is expected to increase[3].

HIE to support care coordination with LTPAC providers is a timely topic as HIE is expected to help achieve national health policy goals (e.g., reduce hospital readmissions) and transform delivery and payment systems with new, improved models of care coordination. Sharing and exchanging health information, particularly during transitions of care, can reduce medication errors and other adverse events associated with preventable hospitalizations[4,5,6]. Front line nursing home staff and their patients, who are composed mostly of nursing personnel, will benefit most from these exchanges.

Funding initiatives and incentives, such as those funded and authorized under the Patient Protection and Affordable Care Act[7] promote and highlight the importance of care coordination around transitions and shared care. These initiatives and incentives include federal, state, and private healthcare payment and integrated care delivery models such as Accountable Care Organizations (ACOs) and Patient-Centered Medical Homes (PCMHs). Some initiatives are designed to reduce LTPAC transfers to hospitals, including readmissions. In addition, the Health Information Technology for Economic and Clinical Health (HITECH) Act enables development of the nationwide health IT infrastructure that will allow for the electronic use and exchange of health information.

Use of EHR and HIE technology by LTPAC lags behind other sectors despite the benefits and drivers of HIE[8]. Barriers to HIT adoption are well-documented and include differences in clinical processes and information needs between LTPAC and other healthcare providers, costs and limited resources for LTPAC to adopt HIT, and not being eligible for Medicare and Medicaid EHR Incentive Programs. Further, LTPAC EHR solutions are generally outdated and do not support the use of health IT standards expected to enable efficient interoperable HIE.

Despite these barriers, LTPAC providers are participating in initiatives to adopt HIT and exchange information[9] and early studies are showing great promise[10].The panelists' position is that with recognized enablers, such as the right stakeholder groups, use cases, and infrastructure, LTPAC providers want and will adopt and use HIE. In the absence of these enablers, LTPAC providers are developing other ways of exchanging, which are less efficient, not interoperable, and may introduce data security issues. Given this real-world understanding of the state of HIE to support LTPAC, we will engage in discussions around how to move forward and advance interoperable HIE.

Contribution of Speakers

Jennie Harvell will open and moderate this panel discussion. Ms. Harvell is a nationally recognized LTPAC policy and Health IT standards expert, particularly in the area of EHR/HIE initiatives. Ms. Harvell will offer her assessment of the state of HIE to support LTPAC, and provide an overview of key initiatives and strategies to advance HIE in LTPAC. She will discuss current data interoperability and information exchange standards to support common LTPAC HIE care coordination use cases.

Dr. Byrne will present findings from an environmental scan, literature review and key informant interviews on the state of HIE (electronic, other means) to support care coordination for persons receiving LTPAC. She will describe and characterize HIE to support LTPAC, using frameworks to characterize the health IT around HIE. The frameworks capture the care coordination workflow that provide opportunities and use cases for HIE. These frameworks also capture the entities involved, the context and drivers for HIE, types of information exchanged, technology used, and HIE outcomes.

Dr. Alexander's position is that strategies for HIT and HIE adoption in LTPAC must build on existing communication networks to support care coordination and transitions. Strategies include identifying required infrastructure to support HIT and HIE, financial incentives to encourage adoption and networking, and building stakeholder partnerships and opportunities for collaboration among healthcare providers. He draws on preliminary findings from an AHRQ-funded 4-year study about the relationship of HIT adoption to nursing home quality measures[11], findings from a CMS Innovations demonstration project on care coordination, communication, and workflow in nursing homes using HIE technology, and working with hospitals to reduce hospital readmissions[8].

Ms. Dougherty's position is that exchange is a common practice in LTPAC using various methods including electronic HIE through an HIE organization, but that interoperable solutions are relatively non-existent and/or don't address clinical processes relevant to LTPAC. She will include case study results to illustrate how technology is being used to support shared care and care transitions between LTPAC and their clinical partners, including which care staff are using HIE and how, the types of information that are exchanged, and the means of exchange. Ms. Dougherty will identify the gaps in technical approaches to support exchange (e.g., to support medication reconciliation), challenges for engaging LTPAC in HIE (lack of needed clinical information available through an HIE organization to support processes), and opportunities to accelerate interoperable HIE by LTPAC providers.

Expected Discussion

Ms. Harvell will synthesize the panelists' positions and then lead an interactive discussion around identified themes. Expected discussion includes:

- Important barriers that need to be overcome so that interoperable HIE can be successfully used by LTPAC providers to support care coordination and safe transitions.
- Whether financial incentives are sufficient to break through longstanding LTPAC/medical care boundaries that have impeded information exchange.
- LTPAC industry's readiness, benefits and risks for participating in electronic/interoperable HIE.
- Feedback on the opportunities identified by the panelists to accelerate interoperable HIE by LTPAC and if there are other opportunities.

- How the AMIA community can accelerate the development of tools and systems to support HIE and build the evidence base on the effectiveness of HIE interventions in LTPAC.
- Whether the identified barriers to 21st century information exchange can be mitigated by effective integrated care models, and as these models continue to evolve, what elements must be put into place to support full participation of LTPAC as key HIE trading partners in integrated delivery systems.
- How the AMIA community can help better define and validate measures that reflect HIE, electronic and other means, to support care coordination across providers, including LTPAC providers.

Data Governance Dilemmas for Research and Clinical Care

Bonnie Kaplan, PhD, FACMI, Yale University, New Haven, CT; Paul R DeMuro, CPA, MBA, MBI, JD, Oregon Health & Sciences University, Portland, OR; Frank Pasquale, JD, MPhil, University of Maryland, Baltimore, MD; Jan Talmon, PhD, FACMI, Maastricht University, The Netherlands; Peter Winkelstein, MD, MS, MBA, FAAP, University at Buffalo, Buffalo, NY

Abstract

Legal and ethical considerations distinguish between patient care and research. Data collection, protection, privacy, and permissions are governed differently for routine care and research data. Yet, neither patients nor clinicians can so easily separate the two; the distinction is not as clear-cut as it appears. Today's clinical data becomes tomorrow's research data. New technologies, medical advances, and the move toward learning health care systems further blur the distinction. Panelists will discuss and debate how the clinical/research distinction holds up in practice, and whether it should (or can be) refined or eliminated. They address dilemmas that informaticians, patients, clinicians, and policy makers face because of the distinction between research and clinical care as it plays out in electronic record keeping, data quality, data storage, data sharing, data linking, and secondary use. The panel considers such timely and controversial issues as: Exactly which aspects of care, and the documentation of that care, are research, and which are clinical, when many may be both? Should consent procedures differ according to whether treatment is considered research? Should patient care be contingent on permission to use care data for research? Are quality assurance, biobanks, or learning systems data clinical data or research data? When is a record review quality improvement and when is it research? What are the benefits and costs of maintaining the status quo and of proposals for change? How do different approaches compare internationally? Panelists and audience will exchange ideas about how they might like to see regulations evolve.

Legal and ethical considerations distinguish between routine patient care and research. Data collection, protection, privacy, and permissions are governed differently for routine care and research data. Yet, neither patients nor clinicians can so easily separate routine care from research. The legal and ethical distinction is not as clear-cut as it appears.

As one example, the Institute of Medicine's call for "learning health care systems" has focused attention on the need to use individual patient data collected in the course of clinical practice to improve health care in general. In a learning health care system, patient data is used for continuous quality improvement and to produce knowledge useful throughout the health care environment. These goals for learning health care systems render obsolete the distinction between data use for patient care and data use for research. Some authors controversially advocate requiring patients to allow their data to be used for research, and some institutions routinely make this requirement a condition of care. Further, as observational studies are increasingly replacing randomized controlled trials, patient care data also is research data. What is the purpose of the clinical/research distinction when today's clinical data becomes tomorrow's research data?

Newer developments may make the clinical/research distinction even more problematic and relevant for informaticians. Data shared through health information exchanges (HIEs) and the US National Health Information Network (NHIN) are a natural basis for research studies. Genomic and clinical data are needed for research to develop personalized targeted therapies. Biobanks collect specimens and related data from clinical procedures, data that later may be used for research. Is all this research data or clinical data? Which regulations apply? Data generated from experimental medical devices, mobile health devices, and sensors that broadcast physiological readings and other health indicators for inclusion in patient records, and patients' self-reports, present additional considerations. What might be learned from data governance approaches in different countries and how would international clinical and research collaborations be affected by governance differences?

Panelists will discuss and debate how the clinical/research distinction holds up in practice, and whether it should (or can be) refined or eliminated. They address dilemmas that informaticians, patients, clinicians, and policy makers face because of the distinction between research and clinical care as it plays

out in electronic record keeping, data quality, data storage, data sharing, data linking, and secondary use. Each panelist will outline areas where the clinical/research distinction creates legal, clinical, research, policy, or ethical difficulties and propose possible solutions. Bonnie Kaplan, past chair of the American Medical Informatics Association's Ethical, Legal, and Social Issues Working Group, will introduce the issues and moderate the panel. Health law expert Paul De Muro begins by reviewing laws and regulations that govern each area, pointing to overlapping and divergent areas that are problematic in their application, and to needed changes in light of technological developments. CMIO Peter Winkelstein, Executive Director of the University at Buffalo Institute for Healthcare Informatics, presents difficulties these distinctions create for clinicians, researchers, Institutional Review Board members, and HIT institutional policy committees, based on his experience in all these roles. Jan Talmon, a medical informatician from the Netherlands and past co-chair of the AMIA Evaluation Working Group, will present the approach of the Dutch Academic Centers to collectively establish prospective biobanks for which data are collected as much as possible during the clinical encounters. Health law privacy scholar Frank Pasquale explores what becomes of patient record (clinical or research) data, focusing on consequences of the distinction for social benefit and for patient privacy. He discusses opportunities (and perils) of new forms of health information exchange and addresses the role of regulators in trying to improve the health care innovation environment. The panel thus addresses such timely and controversial issues as: Exactly which aspects of care, and the documentation of that care, are research, and which are clinical, when many may be both? Should consent procedures differ according to whether treatment is considered research? Should patient care be contingent on permission to use care data for research? Are quality assurance, biobanks, or learning systems data clinical data or research data? When is a record review quality improvement and when is it research? What are the benefits and costs of maintaining the status quo and of proposals for change?

After brief panelist presentations, panelists and audience will exchange opinions on data governance and ideas about how they meet regulatory requirements and how they might like to see regulations evolve.

Learning objectives

After participating in this session, participants should be better able to:

1. distinguish between clinical and research health care data based on legal, ethical, and regulatory distinctions;
2. resolve dilemmas created by legal, ethical, and regulatory distinctions between clinical and research health care data; and
3. evaluate implications of new technologies and medical advances in terms of legal, ethical, and regulatory distinctions between clinical and research health care data.

Intended Audience:

The session is relevant to all American Medical Informatics Association Symposium attendees involved in collecting, distributing, and analyzing health care data; regulatory issues; Institutional Review Boards (IRBs); Quality Improvement (QI); data and biobanking registries and repositories; Health Information Exchanges (HIEs); data science and analytics; and patient consenting.

PANELISTS

Paul R. DeMuro, CPA, MBA (Finance), MBI (Biomedical Informatics), JD, FHFMA, FACMPE, CHC National Library of Medicine Post-Doctoral Fellow in the PhD program in Biomedical Informatics, Clinical Informatics Track, at Oregon Health & Science University School of Medicine Department of Medical Informatics and Clinical Epidemiology; Co-Chair, Healthcare Information & Technology Group, Schwabe, Williamson & Wyatt. In his 35th year of practicing health law, Paul is a legal architect who designs clinically integrated health system models using informatics for aligned financial incentives. Paul's main area of research interest is the use of informatics tools to improve quality and cost-effectiveness. Paul is a former Chair of the American Bar Association Health Law Section. He will address such issues as: the current state of the law and regulations governing data collection, privacy, and security; and how they have not kept up with advances in care and research. He also will address special issues involved in the use of mobile medical applications, mHealth, and social media in the context of the issues which will be discussed by the other panelists.

Bonnie Kaplan, PhD, FACMI, of the Yale Center for Medical Informatics, is a Yale Interdisciplinary Bioethics Center Scholar, and a Faculty Fellow of the Yale Law School's Information Society Project. She has long experience in evaluating effects of health information technology on people and organizations. She is a past chair of the American Medical Informatics Association's (AMIA) Ethical, Legal, and Social Issues Working Group; AMIA's People Organizational Issues Working Group; and the International Medical Informatics Association's (IMIA) Organizational and Social Issues Working Group. Her research addresses informatics ethical, legal, and privacy issues; user perspectives and experiences with health information technology; and ethnographic sociotechnical evaluation. She is a Fellow of the American College of Medical Informatics, and currently a Hastings Center Visiting Scholar. She will outline the issues and advocate for simpler patient consent practices that are the same for both research and clinical data use.

Frank Pasquale**,** JD, MPhil, is Professor of Law at the University of Maryland and Affiliate Fellow at Yale Law School's Information Society Project. His article "Grand Bargains for Big Data" (*Maryland Law Review,* 2013) articulates a broad policy framework for health data governance. His book *The Black Box Society: The Hidden Algorithms Behind Money and Information* (Harvard University Press, 2014) offers a broader perspective on data practices. His research agenda focuses on challenges posed to information law by rapidly changing technology, particularly in the health care, Internet, and finance industries. Pasquale has been a Visiting Fellow at Princeton's Center for Information Technology, a Visiting Professor at Yale Law School and Cardozo Law School, and the Schering-Plough Professor in Health Care Regulation and Enforcement at Seton Hall Law School. He has presented before a Department of Health & Human Services/Federal Trade Commission Roundtable and panels of the National Academy of Sciences on new challenges raised by personal health records and pervasive sensor networks. He will address the benefits and pitfalls of regulatory changes and their effect on innovation in health information exchange.

Jan Talmon, PhD, FACMI, Emeritus Associate Professor in Medical Informatics at the Maastricht University, Maastricht, The Netherlands, is a member of the central team of the Parelsnoer Institute (String of Pearls Institute, PSI), a collaboration among the eight academic medical centers in the Netherlands for prospective biobanking. He is past co-chair of the American Medical Informatics Association's (AMIA) Evaluation Working Group, he is co-editor of the *International Journal of Medical Informatics*, and is a Fellow of the American College of Medical Informatics. He will address the governance model of the PSI and the approach taken to address the legal and ethical issues related to the use of clinical data for clinical research. Responsible for PSI's data model, he will describe the different disease-dependent approaches in which some institutions have fully harmonized the data collected in practice and in care, while others have add-ons for research purposes, but all collect data for clinical audit which overlaps with what is collected for research purposes. He will relate this approach to the more general rules of conduct that govern secondary use of health data in the Netherlands.

Peter Winkelstein**,** MD, MS, MBA, FAAP serves as Executive Director of the University at Buffalo Institute for Healthcare Informatics (IHI) and as chief medical informatics officer (CMIO) of both UBMD, the multispecialty faculty practice of UB physicians, and Kaleida Health, the largest healthcare provider in Western New York. He is a physician executive with extensive experience in medical management and medical informatics, including big data and data science. Dr. Winkelstein has served in multiple medical and informatics leadership roles and his background in clinical, administrative and technological medicine enables him to interface effectively with multiple healthcare environment stakeholders. The mission of the IHI is to support big data healthcare research and economic development at UB and its partners by providing a secure computing environment, data science and security consulting, and extensive healthcare datasets. As CMIO, Dr. Winkelstein sees the EHR as not only supporting clinical practice, but also as collecting clinical data that can be used for quality improvement and academic research. Dr. Winkelstein is Professor of Clinical Pediatrics at UB and a Certified Medical Staff Leader. He will address such questions as: How do you deal with the need to use repositories for both clinical/operational questions (HIPAA) and research (IRB)? How do you distinguish QA/QI (HIPAA) from research (IRB) and is such a distinction meaningful or useful (especially in the context of "learning health care systems")? When should explicit consent be required to use patient data for research—always, never, sometimes?

Towards Developing an Undergraduate Interprofessional Biomedical Informatics Course

Saif Khairat, PhD, MS[1], Martha B. Adams, MD, MA, FACP[2], Glynda Doyle, RN, MSN[3], Elaine Ayres, MS, RD[4], Tiffany F. Kelley, PhD, MBA, RN[5]

[1]University of Minnesota, Minneapolis, MN; [2]Duke University, Durham, NC; [3]British Columbia Institute of Technology, Vancouver, Canada; [4]National Institutes of Health, Washington, DC, [5]Nexus Consulting, Boston, MA

Participants

• Organizer, Moderator, and Panelist: Saif Khairat, PhD, MS, Institute for Health Informatics, University of Minnesota

• Panelist: Martha B Adams, MD, MA, FACP, Duke Center for Health Informatics, Duke University

• Panelist: Glynda Doyle, RN, MSN, British Columbia Institute of Technology

• Panelist: Elaine Ayres, MS, RD, NIH Clinical Center, National Institutes of Health (NIH)

• Panelist: Tiffany Kelley, PhD, MBA, RN, Nexus Consulting

Abstract

Biomedical Informatics training has expanded to include almost all clinical specialties. Whether it is a Masters, PhD, or even the new Sub-Specialty in Clinical Informatics, graduate students and/or returning professionals have various informatics training options. However, Informatics education at the undergraduate level is not as well established. Despite initiatives such as TIGER and the Health Information Technology Scholars Program there is still a need to provide interprofessional education. As Informatics continues to grow and healthcare becomes more complex and data driven, there is a growing need to introduce fundamental concepts to undergraduate students to enhance their knowledge base and stimulate interest in the career of biomedical informatics.

The panelists are leading efforts to develop a Biomedical Informatics course that addresses fundamental concepts and core competency skills. This panel will explore the needs and challenges to build an undergraduate course that includes core competencies for various clinical specialties including medicine, nursing, and allied professions such as nutrition. The proposed course will serve as a foundation for health professionals, which is different from the advanced ONC funded Health IT Workforce Curriculum Components. Panelists specifically aim to further understand the expectations of the AMIA community with regards to developing an interprofessional informatics course. This course will be designed to accommodate undergraduate students. This effort intends to provide fundamental knowledge of Biomedical Informatics to pre-med, allied health, and IT undergraduate students. The aim is to present students with a general overview of the role of Informatics in clinical, research, and operation practices and hence, facilitate determining future career directions.

Learning Objectives

• Better understand the needs for interprofessional undergraduate informatics courses

• Identify core undergraduate informatics competencies (general and specialty specific)

• Learn about on-going and future efforts to integrate informatics in undergraduate education

• Collect feedback on the initial structure of the course

• Identify and invite qualified Informatics professionals to content writing

• Provide a report summarizing audience opinions

Audience

Due to its high relevance, this session will be of interest to all AMIA members.

Topic controversy

The controversy of undergraduate informatics lies not in the topic, rather in the presentation, structure, and organization of an undergraduate course. A multidisciplinary field such as Informatics includes multidimensional views and opinions, and the integration of all opinions may be a challenge. Therefore, the debate remains to be identifying the main goals of the course and its core competencies. For that reason, panelists and the audience will discuss what needs to be included in an undergraduate Informatics course, and what is considered advanced knowledge and skills.

Panelist Presentations

Saif Khairat, PhD, MS has been involved with Health Informatics since 2006. He is a Clinical Assistant Professor at the Institute for Health Informatics at the University of Minnesota. Dr. Khairat is the Co-Principal Investigator to a federal grant award from the Health Resources and Services Administration (HRSA) entitled "Telehealth Resource Center Grant Program", at the University of Minnesota. Dr. Khairat earned his PhD in Health Informatics at the Informatics Institute at the University of Missouri with a focus on ICU clinical communication. During his Informatics training, Dr. Khairat worked as a Research Fellow at the Division of Clinical Informatics at Harvard Medical School. He also has track record of computer science training. Prior to pursuing a career in Health Informatics, Dr. Khairat has been involved with the design and development of Health IT systems. Dr. Khairat is lead author to numerous publications and serves as a scientific reviewer to national and international conferences and journals.

Dr. Khairat is the currently the Chair-Elect of the Education Working Group at AMIA, member of the AMIA Working Group Steering Committee, and he has served on Student Working Group committees. Among other goals, Dr. Khairat intends to develop an undergraduate Informatics course within his term period. Dr. Khairat also serves on the Clinical Informatics Board Review Course (CIBERC); he participates to the development of exam questions for the Simulated Exam.

Dr. Khairat is the Co-lead of the EHR Task Force at the University of Minnesota. Dr. Khairat developed a set of core competencies that aim at identifying and acquiring electronic health records and informatics systems tools around which a high quality curriculum can be developed to educate and train health professions students and informatics specialist students at all levels within the context of interprofessional education and collaborative practice.

Dr. Khairat will address the importance of undergraduate informatics education; he will provide an overview of current progress of the proposed course. Dr. Khairat will talk about the course structure, the need for highly trained informaticians to participate in content development, and the need for content reviewers. He will pose questions to the audience related to the need for an undergraduate informatics course.

Martha B. Adams, MD, MA, FACP is a member of the Duke Center for Health Informatics. She is an emeritus professor, a clinician in applied informatics (handheld technology, telegenetics, information security, social media), author of an enterprise-wide research data security plan for Duke and co-founder of an antimicrobial stewardship framework deployed at Duke University Hospital and 30 hospitals in the Netherlands; she is recently advisor to projects of continuous learning quality improvement and another in personalized medicine involving genomics and cardiovascular disease. Her leadership and informatics track record position her well in academia as former vice chair for clinical affairs in the Department of Medicine, member of the Curriculum Committee of the School of Medicine at Duke, and the University's Academic Council and Open Access Advisory Group. She continues membership in the AAMC Group on Information Resources, its Security Working Group.

Dr. Adams will provide insights from her own career and the challenges of implementing informatics education. She will submit provocative questions for the panelists and audience about solutions, all towards stimulating career interest and responding to the goal set by the Institute of Medicine that, "by the year 2020, at least 90% of clinical decisions will be supported by accurate, timely, and up-to-date information that reflects the best available evidence", a goal that requires more than technology, it requires an interdisciplinary approach of the science and how we use data.

Glynda Doyle. RN, MSN teaches at the British Columbia Institute of Technology (BCIT) in Vancouver, British Columbia. She completed her MSN at the University of British Columbia in 2011 where she first discovered her passion for health informatics. Ms. Doyle is focused on the integration of informatics into the BCIT Bachelor of

Science in Nursing (BSN) and Specialty Nursing curricula. She is particularly interested in the role of mobile technologies and their impact on nursing student's clinical judgment and decision making.

Ms. Doyle has many years of national and international experience in critical care in South Africa, the United Kingdom and the United States. She has been teaching at BCIT in the BSN program since 2005, and is dedicated to engaging students with stimulating and relevant educational environments. Although fairly new to the Health Informatics arena, Ms. Doyle is passionate about integrating Health Information Technologies and the Science of Informatics into nursing education to help improve patient safety and quality of care.

Ms. Doyle is a co-investigator in several inter-disciplinary research projects within BCIT and also in collaboration with other Canadian nursing schools studying the impact of mobile devices laden with clinical resources, social networks and e-portfolios on nursing students and their education.

Ms. Doyle intends to ensure that there is a strong nursing component to the development of this course and is aware of the extensive work already accomplished in the nursing field. She would like to share this information and knowledge with other professionals and provide support to educators who are not informaticians but who are tasked with the integration of informatics in their programs and courses. She would also like to see this course available not only in its entirety to educators, but also as subsections to support the integration of informatics into undergraduate courses such as Ethics, Professional Practice, Evidence Based Practice and Communication.

Ms. Doyle hopes to gather more information from the audience as to their experiences and knowledge of currently available resources and to hear their suggestions as to how best we can format this course and ensure its relevance to as many undergraduate programs as possible.

Elaine Ayres, MS, RD is a registered dietitian who through training and practical experience now works in the field of informatics. Ms. Ayres completed her undergraduate training in nutrition at Cornell University, and her master's in nutrition at the University of Maryland, College Park. She completed her dietetic internship at the Massachusetts General Hospital in Boston, MA. Trained as a research dietitian, Ms. Ayres was asked to manage a food and nutrition computer system at the NIH Clinical Center in 1992. This was in addition to her responsibilities as the Director of the NIH Dietetic Internship, a post-graduate didactic and experiential training program required for registered dietitians. The NIH Dietetic Internship has always ensured that students were well versed in informatics principles and practices as a result.

Ms. Ayres then spent a decade in hospital administration (1998-2008) learning the business and funding of large IT systems, including the current NIH Clinical Center electronic health record (CRIS). While involved in the implementation of CRIS, Ms. Ayres identified the need to involved dietitians in the selection and implementation of health care systems. Working closely with what is now the Academy of Nutrition and Dietetics; Ms Ayres chaired the Nutrition Informatics Committee and the Subcommittee on Interoperability and Standards. She was also the principle on the Delphi Study to develop nutrition informatics competencies. Ms. Ayres is now the Project Manager for the Biomedical Translational Research Information System (BTRIS) at the NIH Clinical Center.

Ms. Ayres will address how undergraduate program content in informatics can be used to enhance the curriculum of nutrition students, and how specific topics and competencies from the nutrition domain will serve to enhance the understanding and engagement of students in other disciplines. Audience suggestions on how to maximize the value of interdisciplinary undergraduate education in informatics will be solicited.

Dr. Tiffany Kelley, PhD, MBA, RN is a Registered Nurse for 11 years, currently; she is a Senior Consultant at Nexus Consulting and the founder of Nightingale Apps, a Health information technology company offering mobile applications to nurses in hospital settings. She earned a PhD in Nursing from Duke University with a focus on Health Informatics and an MBA from Northeastern University. She was the past chair of the Student Working Group and the elected Student Representative to AMIA Board of Directors. She has lead numerous AMIA committees looking to introduce various health profession students to Informatics.

Dr. Kelley will address the vision for an undergraduate informatics course that facilitates pursuing more advanced and specialized informatics training. She will shed light on the challenges novice students face in their post-graduate studies, as well as the challenges of today's professionals in industry and ways to improve training new informatics workforce. Dr. Kelley will talk about the demand for informatics professionals who may not possess graduate education to serve in various organizational roles.

All panelists agree to participation if the panel is accepted.

Innovative Approaches to Medication Reconciliation within the Veterans Health Administration: Designing the 'Magic Pill'

Blake J. Lesselroth, MD, MBI[1,2], Kathleen Adams, MPH[1], Steven R. Simon, MD, MPH[3,4], Kenneth S. Boockvar, MD, MS[5,6], Peter J. Kaboli, MD, MS[7,8]

[1]Portland VA Medical Center, Portland, OR; [2]Oregon Health Sciences University, Portland, OR; [3]VA Boston Healthcare System, Boston, MA; [4]Harvard Medical School, Boston, MA; [5]James J. Peters VA Medical Center, Bronx, New York; [6]Icahn School of Medicine at Mount Sinai, New York, New York; [7]Iowa City VA Medical Center, Iowa City, IA; [8]University of Iowa Carver College of Medicine, Iowa City, IA

Abstract

Medication discrepancies at interfaces-in-care are an important source of preventable iatrogenic injury, causing an estimated 1 million hospitalizations and 7,000 deaths in the US annually at an estimated cost of $500 million annually. While medication reconciliation (MR) has been described as an effective process to surface medication discrepancies and avoid adverse drug events, most institutions have struggled to implement durable MR interventions. The Veterans Health Administration (VHA) features a robust electronic health record and manages the entire medication distribution supply chain from provider order entry to home medication delivery. Consequently, VHA is well positioned to develop and study innovative strategies to manage MR. This panel, which includes clinician-informaticians and health services researchers from across the VHA enterprise, will describe an array of quality improvement initiatives designed to address MR throughout the care continuum. Panelists will discuss: 1) multimedia applications intended to improve clinician accuracy, 2) patient portals to improve patient engagement and self-efficacy, 3) the use of regional health-information exchanges to close information gaps, and 4) implementation studies designed to identify best practices. Panelists will also engage the audience in a dialog exploring the emerging data management and sociotechnical challenges that continue to besiege quality improvement initiatives.

Introduction and Problem Statement

Medication discrepancies at interfaces-in-care are an important source of preventable iatrogenic injury, causing an estimated 1 million hospitalizations and 7,000 deaths in the US annually at an estimated cost of $500 million US annually[1]. Medication reconciliation (MR) a standardized process intended to close gaps in medication information and avoid downstream preventable adverse drug events (PADE)[2]. Although implementations vary depending upon context, the archetypal approach describes four crucial steps including 1) collecting a medication history, 2) comparing the history to institutional records or current prescription orders, 3) identifying and reconciling unintended discrepancies, and 4) documenting and communicating actions and care plans to the next team, patient, or caregiver[3].

While the MR process is conceptually simple and has been shown in the literature to reduce discrepancies, most institutions have struggled to implement durable and highly reliable systems[4]. Even with published toolkits speaking to organizational transformation (e.g. Project Red, IHI's Medication Safety Reconciliation Toolkit, AHRQ's MATCH toolkit), clinicians and healthcare executives report difficulty implementing, acculturating, and sustaining successful MR programs[5]. Also, there are formidable sociotechnical and human factors challenges including cognitive overhead, organizational climate, and patient health literacy[6,7].

The Veterans Health Administration (VHA) has long been recognized as an informatics leader, using an electronic health record (EHR) with physician order capabilities for well over a decade[8]. However, its development largely predates the human factors and usability movement in healthcare. Unsurprisingly, the aging clinician interface does not suitably support the organic and opportunistic characteristics of MR. The VHA, and organizations in general, must model the operational and cognitive requirements of MR systems to inform tools that improve clinician performance and engage patients. Until clinicians and informaticians completely understand MR system requirements, recognize the failure modes that beset MR implementations, and consider the patient as a user in the design paradigm, developers will be doomed to commit the same design missteps and organizations will continue to wrestle with costly, poorly designed, and potentially ineffective tools.

Interactive Panel Aims and Description
The VHA has the medication data and technology infrastructure to prototype and pilot MR strategies addressing common implementation barriers and known failure modes. Presently, the VHA is engaged in a needs-assessment phase, testing technology prototypes, studying system performance, and building an evidence-based foundation to support enterprise-wide programs. This work figures prominently at a time where there are tightening medication safety accreditation standards for healthcare organizations and more stringent meaningful use expectations for EHR technologies. While many organizations emphasize compliance over intent, investing misplaced confidence in routine procedures, most front-line clinicians recognize MR is only partially effective and potentially toxic (like any new class of treatment). This symposium will present some ways in which improvements are being implemented and tested to get to "next generation" MR.

This panel assembles clinician-informaticians and health services researchers engaged in MR research and development across the VHA to discuss quality improvement initiatives for inpatient, outpatient, and home health settings. Each discussant will describe a major MR project within their portfolio, using each case study to highlight lessons learned and controversial informatics issues impacting implementation success. Approximately half of the time will be dedicated to an interactive question-and-answer format intended to engage audience members. Topics for discussion will include: 1) the hidden complexity of MR tasks, 2) the overlooked human factors requirements of MR, 3) the resource burden of strong MR systems, 4) the role of the patient as a participant in MR, 5) the weak cultural climate of implementation within many organizations and 6) the generalizability of work to non-federal systems. Both panelists and audience members will have an opportunity to ask questions.

Panelist 1: Blake J. Lesselroth MD, MBI is a teaching hospitalist, applied informatician, and director of a VHA Patient Safety Center of Inquiry (PSCI) – a research and development "clearinghouse" dedicated to the design, implementation, and evaluation of MR technologies. The Center recently completed the design and pilot of a mobile medication review software application. Pharmacists used the software, which pairs prescription data with images, to collect a bedside admission medication history. Human factors methods including user-centered design, simulation testing, and workflow analysis were used to evaluate the target activity system, the potential implementation barriers, and the anticipated effect upon hospital performance. He will describe the technology, the techniques used to measure an implementation, and the sociotechnical lessons learned from a pilot.

Panelist 2: Steven R. Simon, MD MS is the Chief of General Internal Medicine at the VA Boston and a health services researcher at the Center for Healthcare Organization and Implementation Research (CHOIR). His research emphasizes the evaluation of information technology interventions, including consumer informatics portals, to improve the quality and safety of healthcare. His most recent work has focused upon the design of patient-facing MR portals that can be integrated within the VHA's personal health record, MyHealtheVet. He will be discussing the challenges of using technology to improve home-bound patients' healthcare. He will focus upon barriers to patient technology adoption, the role of secure-messaging mediated MR, and future strategies for using patient-centered technologies to engaged patients and care-givers with medication adherence and monitoring.

Panelist 3: Kenneth S. Boockvar, MD MS is an academic geriatrician, primary care provider, and health services researcher at the James J Peters VA Medical Center in the Bronx, New York. He is also Associate Director for a regional VHA Geriatric Research, Education, and Clinical Center (GRECC). He has been principal investigator on two studies that used mixed methods to examine the implementation of inpatient MR, and health information exchange-enhanced discharge MR. He has published extensively on the topic of MR and was one of the first investigators to measure a direct and measurable relationship between medication discrepancies and adverse events. His VA is currently participating in the Bronx Regional Health Information Organization (RHIO) and he directed a VA project adapting inpatient MR processes to include RHIO access. He will describe the use of this VA-non-VA exchange to enhance MR, reflecting upon preliminary measures of effect, barriers to implementation, and observations of providers using the system. He will also forecast how VHA activities may support the transformation of larger regional health networks.

Panelist 4: Peter J. Kaboli, MD, MS is a teaching hospitalist and health services researcher with over a decade of experience directing and evaluating hospital-based quality improvement interventions. He is currently a co-investigator on an ambitious multi-center MR implantation study that also includes the Partners Healthcare System and Northwestern University. The goals of the Multi-Center Medication Reconciliation Quality Improvement Study (MARQUIS) are to operationalize MR best practices for the inpatient setting and evaluate the effect upon unintentional medication discrepancies. He will be discussing human factors lessons drawn from a discharge process re-engineering initiative using health record technologies and clinical pharmacists. He will also share

insights on the MARQUIS study, including study design, measurement decisions, current progress, and important opportunities for further research.

Moderator: Kathleen Adams, MPH is an informatics research manager and usability specialist at the Portland VA Medical Center. She has over 20 years of research experience in the areas clinical outcomes research, applied informatics, technology usability, and implementation science. A certified Clinical Research Professional, she serves as an Associate Director of the VA Clinical Research Alliance which promotes research best practices through education, mentorship, and outreach.

Intended Audience

The topics covered in this interactive panel discussion should appeal to AMIA members since MR is an interdisciplinary effort leveraging implementation science, healthcare quality, decision support systems, consumer informatics, human factors, and health data exchange. The panel is comprised of clinician-educators and health service researchers with expertise in requirements development, process implementation, and outcomes measurement.

A significant part of the session will be dedicated to an interactive dialog with the audience. Attendees will be able to pose questions to the panelists. We also hope to gather feedback and insights from the audience. Important questions to consider include:

- What components of MR are the most challenging to implement or measure?
- Do facilities and clinicians share an accepted set of definitions for MR activities?
- What are the most important steps informatics specialists can take to support broad adoption of MR
- What software or technologies do you think are needed to support MR?
- What information would increase clinician trust in the accuracy of recorded medication information?
- What are some of the unintended consequences of MR programs?
- What measures do you believe would be the most meaningful to support QI efforts?

Learning Objectives

After participating in this interactive panel discussion session, the learner should be better able to:

- Describe at least four informatics strategies the VHA is piloting to improve the quality of MR
- Identify at least two barriers that frequently undermine successful MR program implementations
- Propose how informatics can be used to improve patient engagement or self-efficacy with regard to MR
- Select metrics to evaluate MR system usability, deployment effectiveness, and tool performance or effect
- Identify at least three research gaps or development opportunities in the domain of MR informatics

Predictive Analytics in Healthcare (HPA): Considerations and Challenges
Moderator: Suchi Saria, PhD
Assistant Professor of Computer Science, Health Policy and Informatics, Johns Hopkins University, Baltimore, MD

The US healthcare system struggles with high cost, poor quality and uneven performance. Electronic predictive algorithms are becoming widely recognized by caregivers, policy makers and practitioners as a means for achieving the Triple Aims. Such algorithms have shown tremendous promise in other industries, and have fueled the recent "big data" revolution. Successful adoption in healthcare, however, will require careful consideration of issues surrounding HPA. In September 2013, the Moore foundation in collaboration with other industry stakeholders and Health Affairs assembled experts from informatics, health services, computer science, bioethics, and law to identify key challenges for HPA, and plan a roadmap for progress. The panelists will begin by presenting takeaways on four key questions regarding HPA: What have we learnt from past deployments? Where the most promising opportunities are in the near term and what are the current barriers for adoption? Should HPA be regulated? How should informatics education adapt to improve HPA adoption? An open discussion will follow with the goal of identifying opportunities and priorities for HPA.

Since clinical decision support, population health, and risk stratification are important applications of HPA, and of critical interest to the AMIA community, we hope this panel will generate insightful and productive discussions.

Enhancing Patient Engagement in the Inpatient Care Setting

David K. Vawdrey, PhD[1], Patricia Dykes, RN, PhD, MA[2], S. Ryan Greysen, MD, MHS, MA[3], Ann O'Brien RN, MSN[4], Jaap Suermondt, PhD[5]

[1] Department of Biomedical Informatics, Columbia University, New York, NY

[3]University of California San Francisco School of Medicine, San Francisco, CA
[4]Kaiser Permanente, Oakland, CA
[5]Hewlett-Packard Laboratories, Palo Alto, CA

Abstract

Patient engagement has been compared to a "blockbuster drug" that has potential to improve the quality and reduce the costs of healthcare. This panel will explore how health information technology—specifically tablet computers—can facilitate patient engagement in the inpatient care setting. The panelists will summarize their individual experiences leading projects at their respective institutions where tablet computers have been employed to deliver tailored information to patients and to enhance patient-provider communication. These projects represent a variety of hardware/software platforms, EHR systems, patient populations, and organizational models. The panelists will discuss the current and future state of inpatient engagement technology, debating topics such as: 1) what information should be shared with patients, and in what form should it be displayed; 2) how to best engage patients' family members and care partners while protecting patients' privacy interests, 3) how can technology support patients with low health literacy and health numeracy, and 4) how have institutions' patient engagement efforts affected frontline physicians, nurses, and other healthcare providers. Ample time will be provided for audience questions and group discussion.

General Description

"If patient engagement were a drug," wrote health information technology consultant Leonard Kish in 2012, "it would be the blockbuster drug of the century and malpractice not to use it." A key ingredient of patient engagement is access to timely, clear, and understandable information for patients and their caregivers. As anyone who has been a hospital patient or witnessed the hospitalization of a loved one knows, the lack of information in the inpatient care setting contributes to anxiety and feelings of helplessness (1). Cumbler and colleagues reported that only 28% of hospital patients were provided with the opportunity to review their inpatient medication list (2), and O'Leary and colleagues found that just 32% of the hospital patients that they surveyed could correctly name even one of their hospital physicians (3).

Health information technology can support patient engagement. Foundational work in this area was performed by Safran and colleagues (4), Mandl and colleagues (5), and others (6), but until recently, it has not been feasible to disseminate the applications they developed into broad clinical practice. With the rapid adoption of electronic health records, personal health records, and mobile devices such as tablet computers, informaticians are creating novel and exciting systems to support patient engagement.

This panel will educate healthcare providers and informatics professionals about the benefits and challenges associated with the use of tablet computers to enhance patient engagement in inpatient care settings. The members of the panel have extensive experience implementing and evaluating patient engagement technologies across a variety of care settings using commercial and locally-developed EHR and PHR systems. Panel members will synthesize their perspectives on the biomedical literature and likely future developments in this area, exploring the following diverse set of topics and engaging in thoughtful discussion based on questions from the audience.

Discussion Topics

Determining what information should be shared with patients
The federal Meaningful Use financial incentive program requires eligible hospitals to provide patients the ability to view online, download and transmit their health information within 36 hours of discharge. In their experience with inpatient information sharing, panelists have discovered that patients increasingly want greater access to their information while they are in the hospital. At the same time, there is concern that patients may misunderstand or misinterpret information, resulting in increased anxiety and more work for nurses and physicians. Many clinicians anticipate that if patients have greater access to the inpatient records, the content of progress and consult notes may change, possibly hindering clinician-to-clinician communication.

Engaging patients' family members and care partners while protecting patients' privacy interests
In a recent JAMA editorial, Bates and colleagues explained that "health care systems today do not optimally identify or engage [lay caregivers] and frequently even push them away by creating barriers to obtaining patient information that may help in the care of their family member, often in the name of privacy and security…." There is general agreement that with appropriate privacy and security safeguards, a patient's family members can play a crucial role in managing information and helping to plan for discharge and follow-up care needs and events. However, how to best establish digital credentials and govern access is an area of considerable debate.

Using information technology to support patients with low health literacy and health numeracy
One of the challenges of using information technology to enhance patient engagement is to prevent an increase in the Digital Divide, where educated, affluent, tech-savvy patients benefit while disadvantaged populations are left behind. The panelists have considerable experience working with patients from minority backgrounds, who don't speak English, and who come from economically disadvantaged communities. The panelists will discuss tablet computers as a bridge to overcome health literacy and numeracy barriers.

Understanding the impact of patient engagement technology on physicians, nurses, and other healthcare providers
Health information technology systems have frequently been perceived as causing additional work for care providers. The panel will present evidence about the effects of patient engagement interventions on staff workload, satisfaction, and patient-provider communication practices.

Assessing the influence of patient engagement technology on patient satisfaction
Hospitals across the U.S. have a growing number of reasons to focus on patient satisfaction. For example, many healthcare delivery organizations are concerned about the impact that the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey will have on their Medicare and Medicaid financial reimbursement rates as well as their public image. The HCAHPS survey is administered to patients after they have been discharged from the hospital, and includes satisfaction measures relating to communication with nurses, pain management, and patient education among others. Survey results will be publicly reported and will be used in part to determine CMS reimbursement rates. Panelists will discuss the impact of patient engagement technology on patient satisfaction at their institutions, presenting a case for the financial benefits of engaging patients in the healthcare.

Panel Members

Patricia Dykes, RN, PhD, MA is Senior Nurse Scientist and Program Director for Research in the Center for Patient Safety Research and Practice and the Center for Nursing Excellence at Brigham and Women's Hospital (BWH) and Assistant Professor at Harvard Medical School. Her research interests are in quality and safety of care and adverse event prevention, especially as it relates to hospitalized inpatients. While funded by the Robert Wood Johnson Foundation, Dykes and team developed a fall prevention toolkit that significantly reduced falls in hospitals. She has expanded this research to explore the use of technology to provide the core set of information needed by patients and care team members to engage in safe patient care. Dr. Dykes is a fellow of the American Academy of Nursing and the American College of Medical Informatics. She is the author of two books and over 50 peer-reviewed publications, including the 2013 article in Journal of Gerontological Nursing, *Building and testing a patient-centric electronic bedside communication center*, which describes the use of a participatory design process to develop and test an electronic bedside communication center prototype to improve access to health information for hospitalized adults and their family caregivers. The prototype was recently enhanced to include additional tools to support patient engagement in their plan of care and is being implemented and accessed by patients and family caregivers on iPads on the medical intensive care and oncology units at BWH.

S. Ryan Greysen, MD, MHS, MA is Assistant Clinical Professor in the UCSF School of Medicine. His research focus is transitions of care for hospitalized older adults and interventions to improve post-discharge continuity of care including novel uses of patient-centered technology such as mobile devices and social media. Dr. Greysen's mixed-methods evaluation studies have leveraged advanced quantitative and qualitative techniques to inform health policy at the intersection of mobile health, hospital medicine, and geriatrics. His 2014 publication in the Journal of Hospital Medicine shows that hospitalized patients can be more engaged in their care by using tablets to access their patient portal at the bedside and that older or less tech-savvy patients benefit just as much as others if given focused coaching. His ongoing work expands this bedside coaching with portals and integrates mobility sensors to engage older adults/caregivers in goal-setting to avoid complications such as functional decline during hospitalization.

Jaap Suermondt, PhD is Vice President and Director of the Analytics Lab at HP Labs, responsible for the research investments in analytics systems, technologies, and infrastructure as well as applications and visualization, including in clinical informatics. He was previously Director of Healthcare Research at HP Labs, creating a portfolio of projects with clinical partners to develop innovations to improve patient and staff experiences, patient safety, and operational efficiency. Dr. Suermondt holds a PhD in Medical Information Sciences from Stanford University School of Medicine. He is an inventor on more than 40 granted U.S. patents, author of dozens of peer-reviewed publications, a Fellow of the American College of Medical Informatics, and a past program chair for the AMIA Annual Symposium. His most recent publication (*Pediatrics,* February 2014, doi:10.1542/peds.2013-2249) shows an electronic patient dashboard helping to reduce CLABSI's by 70% at a major teaching hospital. He created an ongoing research project called Visual Call Button, currently in trial deployment at a skilled nursing facility, that is aimed to enhance patient engagement by providing language-independent visual communication between patients and staff, improve the ability to track, fulfill, and perform analytics on patient requests and the resulting actions, and provide patients with real-time interactive updates and a feedback mechanism on their care and care plans.

Ann O'Brien, RN, MSN, CPHIMS is the National Senior Director of Clinical Informatics at 36-hospital Kaiser Permanente based in Oakland, California. Her leadership role leverages clinical data and innovative technology to transform nursing care processes and improve outcomes. She is currently a Robert Wood Johnson Executive Nurse Fellow and was recognized by *Modern Healthcare* as one of the Top 25 Clinical Informaticists of 2012. As a nurse informaticist, Ms. O'Brien also is leading Kaiser's initiative to transform care delivery through enabling technology such as the development of clinical information dashboards and providing tailored education to hospital patients using tablet computers.

David K. Vawdrey, PhD will moderate the panel. Dr. Vawdrey is Assistant Professor of Clinical Biomedical Informatics in the Department of Biomedical Informatics at Columbia University and Assistant Director for Medical Informatics Services at NewYork-Presbyterian Hospital. In 2011, he conducted one of first studies of patient engagement using tablet computers in a hospital setting, where iPads linked to the electronic health record were provided to cardiology patients, allowing them to review portions of their charts and interact with their care team members. He is the principal investigator on a project funded by the Agency for Healthcare Research and Quality (AHRQ; R01 HS21816) to investigate hospital patient information needs and how they can be met using information technology.

Participation statement: All members have agreed to participate in the panel.

Patient-Generated Health Data in Practice – Learning from the Early Experiences of Innovators

Jonathan S. Wald, MD, MPH[1,7], S. Trent Rosenbloom, MD, MPH[2], Susan Woods, MD, MPH[3], Carolyn Kerrigan, MD, MHCDS[4], Alistair Eskine, MD[5], Neil Wagle, MD, MBA[6,7]

[1]RTI International, Research Triangle Park, NC; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Veterans Health Administration, Portland, OR; [4]Dartmouth-Hitchcock Medical Center, Lebanon, NH; [5]Geisinger Health System, Danville, PA; [6]Partners HealthCare System, Boston, MA; [7]Harvard Medical School, Boston, MA

Abstract

Patient-generated health data (PGHD) is important for monitoring chronic conditions, treatment adherence, treatment response, symptom severity, satisfaction, and shared decision-making. PGHD arises in a variety of contexts – it may be patient- or caregiver-initiated, passive data from a device, responses to a provider or care team request, or corrections when medical chart information is accessible to the patient. Through these and other uses, PGHD can play a significant role in care quality, patient safety, practice efficiency, and the patient care experience. Innovative organizations are gaining experience in collecting, reviewing, and documenting PGHD. A technical expert panel convened in 2013 on behalf of the Office of the National Coordinator for Health IT examined key PGHD opportunities and issues, supporting PGHD as a federal Stage 3 meaningful use objective. While information submitted by patients can benefit patient care, shared decision making, quality reporting, comparative effectiveness research, quality improvement efforts, and marketing activities, digital PGHD also elicits clinician concern about liability, information veracity, impacts on provider workflow, mismatched provider-patient expectations, and limited resources for timely analysis of PGHD. This interactive panel brings together leading innovators for a discussion of digital PGHD use in a variety of settings and contexts. Topics will include: good practices in selecting apps and data for gathering and managing PGHD; types and value of PGHD; how PGHD is received, reviewed, and documented; provider and patient intentions in using PGHD; policies supporting the use of PGHD; and practical approaches to making PGHD actionable.

Intended Audience

The intended audience includes providers, EHR designers, implementers, management, policymakers, senior leadership, patients, and others concerned with increasing the routine use of patient-generated data in care activites.

Introduction to the Topic

Providers, patients, caregivers, and researchers rely routinely on information obtained directly from the patient. Medical history-taking, specialist reviews of treatments with other providers, nutritional habits, self-management for a chronic condition, medication use, decision-making preferences, and service satisfaction are just a few examples in which information from the patient or caregiver, sometimes referred to as patient-generated data (PGHD), plays an important role. PGHD has been described as data "created, recorded, gathered, or inferred by or from patients or their designees to help address a health concern" and is operationally distinct from data captured in clinical settings by providers in two important ways: (1) patients, not providers, are primarily responsible for capturing or recording these data, and (2) patients direct the sharing or distribution of these data to health care providers and other stakeholders[(1)].

Interest in formalizing the use of PGHD is growing for a number of reasons. Models of care such as the patient-centered medical home (PCMH) are increasing. Developed around the Chronic Care Model[(2)], PCMH highlights the use of between-visit information for any condition that is monitored over time, such as blood pressure and glucose data in diabetes[(3)]. Expanding efforts to focus on patient safety in ambulatory care requires routine review and reconciliation of medications[(4)], which can be facilitated by patient-reported medication information collected at or before a visit to help streamline this time-consuming but important task. The aging population and growing prevalence of chronic disease[(5)] is expanding the number of complex patients – those having multiple conditions, medications, specialist providers, and higher risks of having siloed data and care coordination gaps[(6)]. Greater focus

on cost savings by reducing unnecessary treatments and leveraging shared decision-making as part of the care process requires robust and documented patient preferences in order to support personalized decisions.

A technical expert panel convened in 2013 on behalf of the Office of the National Coordinator for Health IT examined key PGHD opportunities and issues, supporting PGHD as a federal Stage 3 meaningful use objective. In addition to the potential benefits of PGHD to patients, it also elicits clinician concern about liability, information veracity, impacts on provider workflow, potentially mismatched provider-patient expectations, and limited resources needed for timely analysis of PGHD[7].

Aim of the Discussion, Expected Discussion, and Timeliness

The aim is to use panelist experiences designing and implementing PGHD processes to prompt the audience to consider the sociotechnical aspects such as policies, preconceptions, analytic methods, and technical challenges of introducing and working with PGHD. Discussion is expected to encompass opportunities and actual or potential solutions, challenges and fears, and areas requiring further exploration relating to PGHD.

This is an important and timely discussion because leading innovators are already introducing PGHD, many organizations view PGHD as an important component of value-based (instead of volume-based) care, it is rather complex to design systems for the collection and review of many different kinds of data leveraging many different technologies in many different home and practice settings, and PGHD is proposed as a menu item for Stage 3 meaningful use.

Specific Contribution of Each Speaker

This interactive panel brings together leading innovators to discuss their growing experience using PGHD in a variety of provider settings and contexts, given its emerging importance and practical challenges. Topics will include: selecting apps for gathering and managing PGHD; data types; how PGHD is received, reviewed, and documented; data sampling, veracity, reliability, and provenance; provider and patient intentions in using PGHD; policies supporting the use of PGHD; practical approaches to making PGHD actionable; and maximizing the value and business alignment of PGHD.

Moderator: Jonathan S. Wald, MD, MPH, Director of Patient-Centered Technologies, RTI International, Research Triangle Park, NC; Dr. Wald served as an author of the 2012 White Paper on PGHD(1), provided testimony to the HIT Policy Committee on PGHD in June, 2012, and co-chaired the 2013 PGHD Technical Expert Panel. He will provide a brief introduction to the opportunities and challenges of PGHD.

Panelist: S. Trent Rosenbloom, MD, MPH, Director of Patient Engagement, Vanderbilt University Medical Center, Nashville, TN; Dr. Rosenbloom will discuss PGHD in the context of Vanderbilt's My Health Team (MHT) chronic care management program including the use of patient journaling, prompted responses from patients between office visits, and emerging alerts and decision support for patients.

Panelist: Susan Woods, MD, MPH, Director of Patient Experience, Connected Health Office, Veterans Health Administration, Washington, DC; Dr. Woods will discuss plans at the VHA to expand PGHD integration into clinical tools, patient-facing health technologies and web and mobile apps, a framework for an enterprise federated architecture, and policies and clinical process requirements for PGHD.

Panelist: Carolyn Kerrigan, MD, MHCDS, Professor of Surgery, Dartmouth Medical School, Hanover, NH; The successful integration of PGHD into care requires coordination of at least 4 essential elements: 1) leaders to sponsor and help set priorities of the initiative; 2) IT to design and build tools; 3) operations to integrate data capture and end-user review into everyday workflows; and most importantly 4) patients to co-design, test, and use. Dr. Kerrigan will share how this strategy is used to successfully implement PGHD in at least 18 clinical areas at Dartmouth-Hitchcock Medical Center.

Panelist: Alistair Eskine, MD, Chief Clinical Informatics Officer, Geisinger Health System, Danville, PA; Geisinger uses a commercially available EMR (Epic 17-years) with a robust patient portal (233,000 registered patients) and gathers PGHD from rheumatology and heart failure patients. Geisinger uses automated phone message, text-messaging reminders and online tools to engage patients, with plans underway to explore more interactive, real-time social networking strategies and additional telehealth assistive technologies to further engage patients and bring their PGHD into the EMR.

Panelist: Neil Wagle, MD, MBA, Medical Director for Quality, Safety, and Value – PROMs, Partners HealthCare System, Boston, MA; Partners has been working to implement a patient-reported outcome measures (PROMs)

platform for over two years, learning a great deal about decision makers in different clinical settings, workflow, operational issues such as enabling the medical and administrative assistant to administer a PGHD platform, data considerations, risk adjustment, issues of privacy and consent, budgeting, technology policy, and arriving at consensus around instruments both internally and with external parties. In summary, Partners has learned a great deal of theoretical and practical knowledge about implementing a PROMs platform.

[Note: Dr. Mattison, below, will attend the interactive session. If any panelists change their plans and are unable to attend, Dr. Mattison has agreed to join the panel.]

Optional Panelist: John Mattison, MD, Chief Medical Information Officer, Kaiser Permanente, Southern California; Dr. Mattison will discuss his work on a wide range of innovation pilots using social, mobile, motivational apps and avatars to both motivate healthy decisions by patients and to better engage them in their own care. He will expose his taxonomies for both a) how wearable sensors will evolve in three classes, and b) how the torrents of PGHD can be managed from both an analytic perspective as well as for safety net sniffing for escalation from machine to human interventions.

Statement of Participation

All participants have agreed to take part in the panel and have sent CVs to be included in this proposal.

Interactive Panel:
How safe are users of Consumer Health Informatics?

Thomas Wetter, Heidelberg University (Germany) and University of Washington, Seattle (WA); **Mary Czerwinski**, Microsoft Research, Visualization and Interaction (VIBE) Research Group, Redmond (WA); **George Demiris**, University of Washington, Seattle (WA); **Robert C Hsiung**, Dr. Bob LLC, Chicago (IL) **Holly Jimison**, Northeastern University, Boston (MA)

Abstract

Consumer Health Informatics (ConsHI) has proven beneficial for many medical and mental conditions. Since it assigns the patient an active role reliable patient contributions are a necessary condition for safe operation, but cannot be taken for granted when patient physical, mental or emotional states deteriorate. The panel presents different approaches from within and outside ConsHI (Home monitoring of cognitive and physical functions, emotion tracking, behavior in online communities), that allow early detection and curbing of the risks. Routine application of such safeguards creates large amounts of data that must be protected against privacy breaches and that must be made sense of, and it causes additional cost. Patients and policy makers therefore face choices whether to mandate such additional safety when ConsHI services go routine.

Introduction

Consumer Health Informatics (ConsHI) is the discipline of using information and communication technology for services that enable the citizen to safely play an active role in his health prevention, medical care, rehabilitation, and as ambient assistive technology. ConsHI services often have a Personal Health Record as passive data backbone. In this panel we concentrate on so called active ConsHI: services for medical risk assessment, symptom tracking and interpretation, safeguarded discharge after inpatient treatment, psychotherapeutic modules for depressed or phobic patients, dose adaptation to asthma or diabetes patients based on flowmeter or glucose readings and many more. An increasing number of services fully by-pass the classical provision of medical care. Many such approaches have shown promising results that seem to suggest that ConsHI services can step in when human resources in health care run low – which regarding the demographic development they inevitably will.

Under the umbrella of trials IRB supervision and respective tight monitoring of unanticipated risks is in place all time. However, when such services leave the research arena, they may be considered the illegal practice of medicine without in-person contact with patients (Wetter et al; AMIA Annual Symposium, 2013, Panel 73). There are good ethical arguments to change legislation as long as services are safe enough and potential benefits outweigh risks. To inform the ethical discussion, it is timely to explore how safe ConsHI can be made.

Challenges to fail-safe Consumer Health Informatics

Generally, active ConsHI heavily relies on patient contributions to be faithful. Severe conditions such as depression or diabetes may lead to falsely reported signs, concealed information, or non-adherence to advice, with increased risk of critical life threatening events lurking. So patient willingness, capability and emotional stability to cooperate contribute to “safe enough” ConsHI that a provider should check ***before*** offering a contract. We subsequently concentrate on more subtle and harder to catch threats to patient cooperation that develop over time and turn a responsible patient into someone who is a risk for himself. Degrading capability to cooperate may hit a patient in various dimensions. Cognition may fade due to undiagnosed dementia or neural conditions and patients can no longer faithfully report or reliably follow up upon advice. Circumstances of life, side effects of therapies, etc., may affect moods and then behaviors such as discontinuation of a therapy. Bodily functions deteriorate very gradually and patients perform functions at more and more effort. Apparently normal behavioral patterns may already show abnormalities or

signs of exhaustion that can be used to intervene before catastrophic failure. Or a depressive person has his/her ups and downs over time but eventually a down goes so deep that suicide becomes a tangible risk. If such deteriorations happen in the classical in-person care situation the health care professional has a fair chance to notice and intervene in time. If ConsHI strives for an on par role of service provision it faces the challenge of finding technical substitutes for the good senses enhanced by clinical acumen that humans can apply. Health and humanities professionals play an important role in identifying incremental decays in client responsiveness and evaluating conclusions drawn from big data analysis such as the one presented subsequently.

Approaches to reduce risks of failure

Holly Jimison: Safety and Privacy Issues in Home Monitoring and Health Interventions for Older Adults in the Home

With the growth of the elderly population outpacing other age groups, and with an associated escalation of health care resources spent on chronic disease and conditions of aging, new models of care need to focus on scalable and coordinated interventions to the home. Needs assessments have shown that the highest priorities for older adults are to remain independent and age in place. New technology developments ranging from sensors to mobile computing and communications offer promise for effective health interventions for quality of life and independence. However, the monitoring of activities and behaviors, as well as the need to share key data bring up important privacy and data sharing challenges. In interviews and debriefings, we have found that older adults find the benefits of coaching and feedback to be worth the privacy trade-off. The concerns seem to pale in comparison to losing independence and not being able to "age in place." However, it is particularly important to understand and explicitly model data sharing preferences. The challenge in this domain is how best to assess, infer, and implement tailored data sharing protocols. Another safety concern with home monitoring interventions addressed in this panel has to do with automated alerting, often based on noisy and context based data from sensors in the home. We will present a decision theoretic analysis of over-alerting versus missing important safety events, ranging from medication errors to falls. Finally, through monitoring of cognitive performance, as we do through adaptive cognitive computer games and motor speed monitoring, we can improve the safety of ConsHI services by detecting cognitive impairment and reduced client reliability and by adapting the system interfaces and protocols to account for potential cognitive impairment.

Mary Czerwinski: Emotion Tracking for Awareness, Health and Well-being

In emotional tracking for health and well-being, we flip the typical affective computing world on its ear and give the emotional signal back to the user for interpretation. We aim to empower the users with better awareness and tracking capability about their mental state over time. In addition, we attempt to intervene with psychologically relevant activities that are infused with social media, which make the exercises more enjoyable. In this way, we get users to interact with our intervention platform (a mobile phone application with psychologically relevant suggestions to participate in social or individual popular activities and intervention suggestions) for longer periods of time, and we've been able to show that, if they do so, they develop more positive coping strategies. In addition, we've found that the awareness of their affective state alone is useful for behavioral change. Clients of a ConsHI service might be upset through intimidating medical data (labs, tumor markers) or by signs they observe about themselves and interpret as a beginning of a relapse, etc., or an adverse effect of a medication. They may unconsciously try to ignore these signals. This is true even though expedited treatment would be beneficial if not life-saving (e.g., a graft vs. host reaction). Emotion detectors could also react to affective changes caused via bad medical news. This could be general, and all-encompassing across medical conditions. In some future these signals may be able to distinguish negative affect caused by work or family or health

care. But in the near future, these signals could be used to alert ConsHI service providers of the affect changes of their clients that might require referrals to their clients' GP or equivalent before continuing the service. And finally, we do believe that at some point these clients will be ok with sending this longitudinal information to their doctors or caregivers, which can then help them make better decisions about long-term care and what strategies/medications/exercises are working best for that patient. Even if the patient isn't seen in person for long periods of time, doctors and other caregivers can be fully aware of the patient's affective state and interact with that patient "just in time" with directed interventions (possibly through technology in the home).

George Demiris: Creating value from embedded technologies to the safety of older citizens in their homes

Smart homes, namely residential settings with embedded technology that facilitates passive monitoring of residents, generate very large data sets. With the application of sophisticated data mining and pattern recognition approaches it is possible to make inferences about patterns of activities of daily living and ultimately study trajectories of activities over time in order to automatically detect abnormalities and potentially prevent adverse events without having to rely on human observers or self-report. Such technologies are increasingly used in community based housing where individuals with one or more chronic conditions are provided with a safety net for early detection of behavioral abnormalities that point to severe underlying health problems. This approach could potentially empower consumers who can more actively monitor their overall well-being which aligns well with the emerging quantified self movement. However, challenges pertain to a) ensuring algorithms are accurate and the false-positive and false-negative signals do not become burdensome or disruptive to everyday life nor jeopardize residents' safety; b) visualizing the generated information so easy to understand that consumers themselves can process and annotate the generated knowledge; c) integrating clinicians so that the sensor data enhance clinical decision making but do not burden clinicians with new demands on new data sets; and d) addressing ways to maximize the benefit of smart home data for health consumers in terms of access, awareness, and safety. Smart home sensor data can facilitate not only more effective monitoring to maximize resident safety but often support decision making around transitions of care when it may no longer be safe for an individual to live alone or where specialized care and assistance are due.

Robert C Hsiung: How safe are members of online communities (and users of social media) with depression?

Depression can dramatically lower the quality of, and even end, life. The safety of members of online communities (including users of social media) with depression could potentially be increased by a) improving detection of worsening depression and b) facilitating professional intervention. Shame and stigma can prevent people with depression from receiving support from peers and treatment from professionals. Online community members who are anonymous tend, however, to feel less exposed and more free to share how depressed or suicidal they feel. Worsening depression may be detected by automated Natural Language Processing methods at nearly the precision and recall as expert opinion. Detection may also be considered crowdsourced by the forum software to other community members, who may also have more familiarity with depression and be better able to "see through" denial than "real-life" friends and family members. Intervention may be facilitated by alerting affected community members directly, other community members, community moderators, or even the primary care physicians of the community members. To implement the last while safeguarding the privacy of the community members, all that would be required would be for the community members to obtain the agreement of their primary care physicians (false positives would be a risk) and to trust the community management enough to provide contact information for their primary care physicians. Then if their depression worsened, software or community members could initiate an automated and confidential contact process that could include the content of the posts that were considered to indicate worsening depression.

The Impact of HIT on Cost and Quality in Patient-Centered Medical Home Practices

Julia Adler-Milstein, PhD[1,2], Genna R. Cohen, BS[2] Amanda Markovitz, MPH[3], Michael Paustian, PhD[3]

[1]School of Information, University of Michigan, Ann Arbor, MI; [2]School of Public Health, University of Michigan, Ann Arbor, MI; [3]Blue Cross Blue Shield of Michigan, Detroit, MI

Abstract

While health IT is thought to play a critical role in supporting new models of care delivery, we know little about the extent to which HIT improves cost and quality outcomes. We studied a large patient-centered medical home (PCMH) program to assess which types of HIT led to improvements in composite performance outcomes: PMPM cost, chronic disease management, medication management, and preventive care. At baseline, registries were associated with lower PMPM spending (-$19.37; p<0.05). Over time, practices that newly adopted EHRs had smaller gains in chronic disease management adherence relative to non-adopters (diff-in-diff: -1.55%; p<0.05). We failed to find a relationship between other types of HIT – ePrescribing and PHRs/Portals – and our composite outcomes. The lack of consistent relationship between HIT adoption and improved performance suggest that these tools may not yet support the clinical activities and approaches to patient engagement that enable PCMHs to deliver higher-quality, lower-cost care.

Introduction

The HITECH Act seeks to promote widespread adoption of health information technology (HIT) in order to address persistent quality and efficiency challenges facing our healthcare delivery system, many of which derive from reliance on paper records.(1) HITECH also seeks to put in place the infrastructure for broader efforts to reform healthcare delivery by supporting new models of care.(2) While the role of HIT is thought to be critical to achieving these reforms, we know little about the extent to which HIT is impacting the intended quality and cost outcomes. We therefore studied a large program promoting implementation of the patient-centered medical home (PCMH), a new model of care delivery that has received substantial policy attention, in order to assess whether adoption of various types of HIT was associated with improved performance. Assessing the impact of IT on cost and quality performance in PCMH practices was of particular interest in light of recent evidence documenting the shortcomings of HIT solutions to support key PCMH practice activities.(3, 4)

Background

Patient-centered medical homes were developed in response to widely recognized shortcomings in primary care delivery. While the concept has a long history(5), in their modern form they are based on the principles of providing care that is accessible, continuous, comprehensive, family-centered, coordinated, compassionate, and based on trusting relationships.(6) These principles may be achieved by promoting integrated care teams who are supported by information technology. Medical practices and other types of delivery settings across the nation are implementing and assessing the medical home model through federal, state and regional programs. Many have relied on a set of standards for PCMH achievement developed by the National Committee for Quality Assurance (NCQA).

The use of IT in PCMHs is thought to be essential to successfully achieving the key aims of team-based, coordinated care and meaningfully engaging patients.(7) For example, patient registries enable population-level views of clinical data that can help health care providers identify systematic care gaps and opportunities for targeted outreach. Electronic health records can promote teamwork through clinical messaging, task tracking, and creation of shared lists (i.e., a problem list). These functions should also help ensure that care gaps are filled when the patient is in the

office, and that follow-up on critical test results is performed. ePrescribing can further complement these activities by enabling more careful tracking of medications. Another key promise of the PCMH model is the ability to involve patients in their care. Patient portals and personal health records (PHRs) hold the potential to engage patients through making their clinical data accessible to them. These HIT applications can also serve as teaching tools that allow patients to manage their own conditions as well as facilitate effective patient communication with their care team.

There has been no large-scale empirical assessment of the extent to which various types of HIT are enabling PCMH practices to deliver higher-quality, lower-cost care. We therefore leveraged a PCMH program across the state of Michigan to examine whether HIT adoption was associated with better performance at baseline, and then to assess whether those that newly adopt HIT over time realized greater performance gains relative to those that did not adopt.

Methods

Setting

We examine the impact of HIT adoption on cost and quality outcomes within ambulatory practices that participated in the Blue Cross Blue Shield of Michigan's (BCBSM) Physician Group Incentive Program (PGIP). PGIP is a pay-for-performance program that was launched in 2005 to align financial incentives for structural and quality improvement initiatives. Individual physician practices participate in PGIP through a physician organization (PO) intermediary, such as an Independent Practice Association or a Physician-Hospital Association.(8) The 40 POs participating in PGIP represent nearly 15,500 physicians providing care to nearly two million BCBSM members. (9)

One of the flagship PGIP initiatives focuses on promoting transformation into a PCMH. Physician practices are awarded financial incentives for implementing capabilities aligned with the PCMH model - for example, providing 24-hour patient access to a clinical decision-maker by phone and after-hours urgent care access as well as offer education materials to patients during visits. These capabilities are similar to those developed by the NCQA for their PCMH program.(10)

Population Studied

We studied physician practices participating in PGIP over the course of three years between July 2009 and June 2012. This period lags one year behind the launch of the PCMH program in January 2008, providing practices time to establish sufficient capabilities before assessing their impact. We focused our analysis on adult primary care practices that participated in PGIP continuously over our analytic period and had demonstrated that they were pursuing PCMH capabilities (defined as a PCMH score of greater than 0.2 in June 2009 – see below for explanation and interpretation of score). After applying these inclusion criteria, the final analytic sample included 573 practices.

Data sources

Our study relied on data from five sources. The first -- the BCBSM Self-Reported Database (SRD) -- included IT adoption status, physician demographic information, PO membership, practice affiliation (i.e. which physicians make up each practice), a primary care physician (PCP) indicator and practice PCMH capabilities. It is collected semi-annually from PO representatives and the self-reported capabilities are verified by BCBSM at random. The second and third sources of data -- BCBSM member enrollment and claims data – were used to obtain demographic data on members who received care at PCMH practices and then construct cost and quality measures. The fourth and fifth sources of data -- the 2010 United States Census and 2011 American Community Survey (ACS) – were used to create variables to adjust for potential confounding from market area, socio-economic or demographic factors not available through the SRD or BCBSM administrative data.

Measures

HIT Adoption. We used survey questions from the SRD to measure the adoption (yes/no) of four different types of HIT in each practice: (1) electronic health records (EHRs); (2) patient registries; (3) ePrescribing (eRX); (4) patient portals or personal health records (PHRs) at two time points: as of June 2010 and as of June 2011.

Cost and Quality Outcome Measures. We constructed a practice level measure of cost and three composite measures of quality of care.(11, 12) Total combined medical and surgical allowed cost per member per month (PMPM) was calculated to assess cost of care. To assess quality, we calculated composite measures of chronic disease management (e.g., HbA1c testing for diabetic patients), medication management (e.g., annual monitoring for patients on ACE/ARBs), and preventive care (e.g., breast cancer screening). We relied on composite measures because of concerns about sufficient numbers of patients for any individual measure (13) and heterogeneity in performance across individual measures (14). Outcome measures were calculated for July 2009-June 2010 (i.e., the year prior to our first measure of HIT adoption) and July 2011-June 2012 (i.e., the year following our second measure of HIT adoption).

Practice Controls. We included seven practice characteristics calculated from the SRD and administrative claims data as covariates: practice size, primary care focus, BCBSM patient volume, physician turnover, number of years in the PGIP, and practice movement between physician organizations. We calculated practice size through a list of providers' and their practice affiliations using the SRD. We categorized size as follows: solo (1 physician), small (2-3 physicians) medium (4-5 physicians), and large (6+ physicians). Data were not available to capture other measures of practice size, such as number of clinical or administrative support staff. We used the PCP indicator in the SRD to classify practices as 'primary care-only' if only PCPs were present and 'multispecialty' if both primary care and non-primary care specialty physicians were present. Total BCBSM paid services delivered per PCP were calculated annually for each practice as a proxy for BCBSM volume within the practice. We measured physician turnover as the proportion of practice physicians who left the practice in each time period. Average number of years that the practice's PCPs participated in PGIP was used as the measure of the practice's longevity in PGIP. A binary (0/1) indicator identified practices that changed physician organizations between practice-years.

Patient Cohort Controls. We used the primary care attributed member cohort for each practice and their member enrollment information to estimate the two practice level patient characteristics: proportion of members who were female and mean prospective risk score (OptumInsight® Symmetry version 8) for adult patients in the practice. The prospective risk score employs a large national database of aggregated claims and membership information to derive a numerical, diagnosis-based episode assessment used to predict future medical costs.

Market Controls. We examined six zip code-level market characteristics and one PO characteristic to address additional sources of variation that might influence cost and quality outcomes. We calculated the percent of residents who were non-White or Hispanic and the percent of residents who lived in a rural area using zip code data from the 2010 US Census. We used 2011 ACS data to capture median household income and percent unemployment. We further used the BCBSM Provider Enrollment and Credentialing System, which captures 94% of active physicians in Michigan, and 2010 US Census population estimates to measure total PCPs per 1,000 population estimated at the zip code level. Finally, we calculated BCBSM market share at the zip code level based on member subscriber addresses from BCBSM member enrollment information and the total estimated zip code population from 2010 US Census. All zip code measures were weighted for each practice to account for the proportion of their care provided to members residing in each zip code. We measured PO size based on the total number of affiliated practices with at least one primary care physician.

PCMH Score and Cutoff. In order to ensure that practices in our analytic sample represented those pursuing PCMH status, we calculated a PCMH score at the beginning of our analytic timeframe using information on individual PCMH capability achievement reported in the SRD (115 capabilities within 13 domains). We used the methodology of prior studies that relied on the same data(15) by calculating a PCMH score as follows: we assigned capabilities reported as 'fully in place' a value of 1 and assigned capabilities reported as 'not in place' a value of 0. When capabilities had multiple gradients, the capability score was calculated as a proportion of the maximum gradient. For example, the Extended Access domain asked respondents to identify the percentage of appointments reserved for same day scheduling from the following options: 30 or 50 percent. A response of 30 percent implementation on same-day scheduling was assigned a value of 0.6 (0.3/0.5). We calculated domain-specific scores by summing all capability scores within the domain and dividing by the maximum number of distinct capabilities within that domain. This method gives equal weight to each PCMH domain in order to avoid giving greater weight to domains with more capabilities. Finally, we calculated the overall PCMH score as the mean of the 13 domain-specific scores and only included practices that had a score of at least 0.2 (i.e., 20% of PCMH capabilities in place) in order to ensure that practices have demonstrated sufficient ability to achieve PCMH principles.(15)

Analytic Approach

Our research design relies on change over time in HIT adoption among sample practices, comparing practices that newly adopt each type of HIT in the sample between June 2010 and June 2011 to those that always or never had adopted each type of HIT over the same period. This difference-in-differences approach compares change in outcome between the pre-adoption year (July 2009-June 2010) and the post-adoption year (July 2011-June 2012) for new adopters compared to always- or never-adopters. For each of the four outcomes, we used multivariable cross-classified linear mixed models, incorporating a random effect for practice and a cumulative random effect for the physician organization. The cross-classified model accounts for the longitudinal design, clustering of practices within physician organizations, and movement of practices between physician organizations.(16)

Table 1. Practice Characteristics

Practice Characteristics	n=573	n=573
Practice HIT Adoption (count)	As of June 2010	As of June 2011
EHR	302 (53%)	355 (62%)
PHR or Portal	206 (36%)	238 (42%)
eRX	492 (86%)	527 (92%)
Registry	451 (79%)	466 (81%)
Practice Outcomes (median)	July 2009-June 2010	July 2011-June 2012
Adult PMPM	$364.16	$394.68
Chronic Disease Management	79.0%	77.7%
Medication Management	80.0%	80.0%
Preventive Care	78.2%	76.1%
Continuous practice and patient characteristics (median)	July 2009-June 2010	July 2011-June 2012
Mean prospective risk score for adults [4]	1.57	1.71
Percent of attributed members who are female [4]	52.1%	52.0%
Professional services per PCP in practice [4]	1,648	1,502
Average number of years in PGIP for PCPs in practice [1]	2.5	4.5
Turnover of physicians in practice during study year[2]	0.00	0.00
Categorical practice and patient characteristics (count)		
Practice Size [1]		
Solo physician practice	249	243
2-3 physicians	145	151
4-5 physicians	79	81
6 or more physicians	100	98
Practice Specialty [1]		
Primary Care- Only	541	548
Multispecialty	32	25
Whether practice changed POs during study year [2]		
No	566	506
Yes	7	67
PO and market characteristics (median) [3]		
Total practices in PO with a PCP	99	103
Percent BCBSM market share	32.9%	30.8%

Percent non-white residents	18.4%	18.0%
Percent rural	19.3%	19.4%
Number of PCPs per 1,000 residents	0.77	0.79

(1) As of June 2009; June 2011

(2) Change during time periods between June 2009-2010; June 2011-2012

(3) 2010 Census or 2011 ACS

(4) Attribution using claims from July 2008-June 2010; July 2010-June 2012, prioritizing most recent year

Results

In our analytic sample, the majority of practices were solo or small practices with fewer than 4 physicians. (Table 1) The vast majority of practices were designated as "primary care only" practices. There was minimal physician turnover within practices during each study year and few practices changed POs during each study year.

HIT adoption rates were fairly high at baseline: 53% EHR adoption, 36% PHR/Portal adoption, 86% ePrescribing adoption, and 79% registry adoption. (Table 1) There were, however, increases in adoption over time for all types of HIT. Specifically, 53 practices newly adopted an EHR (9% of all practices); 32 practices newly adopted a PHR or patient portal (6% of practices); 35 practices newly adopted ePrescribing (6% of practices); and 15 practices newly adopted a registry (3% of total practices).

Over time, adult PMPM spending increased from an average of $364.16 to $394.68. (Table 1). Performance on all three composite quality measures was essentially flat over time. Chronic disease management decreased slightly from 79.0% to 77.7%. Medication management remained flat at 80.0%. Preventive care decreased slightly from 78.2% to 76.1%.

In multivariable models for our first outcome of interest, adult PMPM cost, we found that, in our baseline year, practices that had adopted a registry had significantly lower cost: coefficient = -$19.37 (95% CI: -$36.17 to -$2.57, Column 1, Table 2). There were no other significant relationships between IT adoption at baseline and PMPM cost. Over time, there was a slight, but non-significant, increase in PMPM cost. Similarly, for all types of HIT, there were no significant difference-in-differences between new adopters and practices who never- or always-adopted.

For our second outcome of interest, chronic disease management, we found no significant relationships between HIT adoption at baseline and performance. (Column 2, Table 2) Over time, there was a slight, but non-significant, decrease in performance for this composite measure. For PHRs/portals, eRX, and registries, there were no significant difference-in-differences between new adopters and practices who never- or always-adopted. For EHRs, practices that newly adopted performed worse over time compared to those that had always- or never-adopted EHRs (difference-in-differences of -1.55%; 95% CI: -2.99% to -0.12%; Column 2, Table 2).

Table 2. Relationship between HIT Adoption and Cost/Quality Outcomes, July 2009-June 2010 compared with July 2011-June 2012

Independent Variable	Adult PMPM	Chronic Disease Management
Practice HIT Implementation		
EHR	$11.47 (-$2.44, $25.38)	0.77% (-0.47%, 2.01%)
PHR or Portal	$7.92 (-$9.34, $25.17)	-0.39% (-1.92%, 1.15%)
eRX	-$8.85 (-$29.17, $11.47)	0.40% (-1.42%, 2.23%)
Registry	-$19.37 (-$36.17, -$2.57)*	0.92% (-0.60%, 2.43%)
Interaction with Study Period		
Study Period	$6.12 (-$28.34, $40.57)	-1.67% (-4.61%, 1.26%)
Study Period*EHR	$1.93 (-$16.62, $20.49)	-1.55% (-2.99%, -0.12%)*
Study Period*PHR/Portal	-$15.33 (-$36.75, $6.10)	0.40% (-1.24%, 2.04%)
Study Period*eRX	-$7.16 (-$38.01, $23.68)	1.61% (-0.99%, 4.21%)
Study Period*Registry	$12.11 (-$10.87, $35.10)	-0.34% (-2.16%, 1.47%)

Practice and Patient Characteristics		
Mean prospective risk score for adults	$225.07 ($207.73, $242.40)*	2.03% (0.27%, 3.79%)*
Percent female	-$3.86 (-$8.85, $1.13)	-0.20% (-0.73%, 0.33%)
Professional services per PCP in practice	-$0.60 (-$3.82, $2.62)	-0.04% (-0.37%, 0.30%)

Discussion

This study is among the first to assess the impact of various types of HIT on key PCMH performance measures. Our results suggest that, at least soon after adoption, there is limited direct impact of HIT. Registries were associated with lower PMPM cost, but when we examined new adoption using a difference-in-differences approach, the only significant relationship was for EHRs on chronic disease management performance and in the opposite direction than predicted (i.e., worse relative performance among new EHR adopters). These results suggest that current HIT tools may not immediately support the types of clinical activities and approaches to patient engagement that enable PCMHs to deliver higher-quality, lower-cost care.

While not all types of HIT were associated with better outcomes at baseline, the fact that registries – a core type of HIT that is emphasized in the PCMH model and often adopted early – were associated with lower PMPM cost coupled with the fact that new EHR adoption led to worse relative performance for chronic disease management may suggest that the impact of HIT varies with time. That is, newly adopted HIT may hurt performance in the near term by disrupting workflows, introducing complexity, and reducing the time that providers can devote to clinical practice transformation. However, once practices become comfortable with the technology and are able to invest in optimizing its use, the benefits may appear. Some of this optimization may also come in the form of more advanced HIT functionalities. Prior evidence suggests that use of clinical decision support is consistently linked with gains in adherence to evidence-based medicine. It is likely that practices that had newly adopted EHRs had not yet advanced to consistent use of alerts and reminders for chronic care, medication management, and preventive care. Over the next few years, data from a longer time horizon will become available and enable these hypotheses to be tested.

Our results may also be explained by the fact that the BCBSM PCMH program does not emphasize HIT to the same degree as other PCMH programs. A 2011 Urban Institute report compared the BCBSM PCMH program capabilities with those of NCQA and found that the BCBSM program focuses less on HIT. As a result, PCMH practices in our sample may not rely as heavily on HIT to pursue the targeted domains of performance improvement. While it will be important to assess the impact of HIT in the context of other PCMH programs, our results suggest that BCBSM may want to consider a greater focus on these tools in the PCMH capabilities they promote.

Our analytic approach includes some limitations that should be considered when interpreting the results. First, we rely on observational data and were not able to adjust for all potential sources of confounding. Of particular concern are time-varying factors, such as workflow changes, that may have been implemented in parallel with HIT adoption. Second, SRD data was provided by PO practice consultants who may not have had in depth knowledge of the status of HIT adoption in each practice, and the data only captured whether each type of HIT was adopted, not the extent to which it was used. It is therefore possible that practices had functionalities available that were not widely used. In addition, for some types of HIT, only a small number of practices newly adopted in the one-year time window, limiting our power to detect an impact on our target outcomes. Further, because adoption rates for some types of HIT were already high (i.e., eRx and registries), our findings likely reflect the effect in late adopters that may have been less interested in adopting and using technology. Third, the composite quality measures had fairly high rates of adherence in our sample (~80%), limiting the opportunity to observe improvement. Finally, we were only able to

look at the impact of HIT adoption in the year immediately following adoption. It may take longer for PCMH practices to realize the benefits of these new tools.

Conclusion

We examined the impact of HIT on cost and quality outcomes in 573 practices that had significantly progressed in patient-centered medical home implementation in a large program. We found that registries were associated with lower PMPM cost and that EHRs appeared to negatively impact quality performance for chronic disease management in the short-run. This suggests that HIT tools may require a longer time horizon to be used effectively or they simply may not yet meet the demands of new models of care delivery that are being promoted under health reform.

Capture of Osteoporosis and Fracture Information in an Electronic Medical Record Database from Primary Care

Sonya Allin, PhD[1], Sarah Munce, PhD[1], Susan Jaglal, PhD[1,2], Debra Butt, MD, MPH[1,2], Jacqueline Young, MS[2], Karen Tu, MD[1,2]
[1]University of Toronto, Toronto, ON, Canada; [2]Institute for Clinical Evaluative Sciences, Toronto, ON, Canada

Abstract

In a large database of EMR records, we explore: 1) completeness in capture of bone mineral density (BMD) T-scores required for diagnosis of osteoporosis; 2) concordance of BMD exam information with other osteoporosis information; and 3) evidence of osteoporosis screening among fracture patients. To explore completeness of exam capture, BMD exams in the EMR were related to a provincial billing database. To explore concordance of information and screening rates, 7500 EMR records were reviewed for osteoporosis and fracture details. Results show that 98% of exams billed to the province for EMR patients were found in the EMR. However, documented osteoporosis was substantiated with BMD results only 55.8% of the time. Of 151 charts for fragility fracture patients, 1 in 4 contained no evidence of osteoporosis investigation. In summary, while EMR information about osteoporosis is of variable quality, EMR records shed light on osteoporosis management indicators and completely capture BMD results.

Introduction

In 2005, the Ontario Ministry of Health and Long Term Care provided funding for the Ontario Osteoporosis Strategy with the goal of promoting appropriate osteoporosis care and preventing fractures in the province[1]. As a part of the Strategy, the Ontario Bone Mineral Density (BMD) Working group has been exploring utilization of BMD testing in the province, specifically. BMD tests provide information required to definitively diagnose osteoporosis[2]; this occurs when a patient's BMD T-score is found to be 2.5 standard deviations or more below the young adult mean. Clinical guidelines currently recommend that all patients over the age of 65 undergo BMD testing in order to screen for osteoporosis, as well as all individuals with a history of fragility fracture[2].

In Canada, some information about BMD testing is available in administrative databases, like the Ontario Health Insurance Plan (OHIP) records. However, while OHIP contains billing information for the province's BMD tests, it does not contain the results required to definitively diagnose osteoporosis (i.e. the BMD T-scores). Incidence of osteoporosis in the Ontario population, then, must instead be inferred from other administrative sources, like prescription information or hospital billings; these sources are known to provide limited accuracy[3]. Administrative data, moreover, does not provide adequate insight regarding about appropriate osteoporosis screening. Specifically, while administrative data indicate rates of post-fracture BMD testing to be low[4], these data cannot identify pathways of care among patients. This means that administrative data alone cannot determine where efforts to improve screening rates should best be targeted[4].

In part due to the limitations of administrative data, researchers have been increasingly turning to Electronic Medical Records (EMRs) in the hopes that these may provide better, more timely and comprehensive information about both osteoporosis incidence and management. EMR data have several advantages over administrative data in that the data include test results and are specific to management decisions that take place within a particular care pathway. The quality of data in EMRs, however, has tended to be variable in part because clinicians use EMRs in a wide variety of ways. For example, many physicians continue to use *both* paper records and EMR records[5]. A 2010 review of EMR usage highlighted the impact of such variability; completeness of blood pressure information captured in EMRs, for example, varied from 0.1% to 51% across studies[6]. EMR data also often has been found to contain misspelled words, missing diagnostic codes, or data that has been entered in incorrect or inconsistent database fields[7,8]. A lack of mature electronic interfaces to EMR has also hindered the completeness of data in Ontario's EMRs; according to the National Physician Survey, in 2010 approximately 40% of family physicians in Ontario

had an electronic interface to diagnostic imaging services[5]. Lack of diagnostic imaging results impacts the completeness of BMD results in EMRs, specifically; a 2005 of EMR records in the U.K. revealed limited capture of these results[9].

Study Objectives

The primary purpose of this study is to provide an updated assessment of data quality related to Bone Mineral Density (BMD) test results in EMRs and to explore the relationship of BMD data to other osteoporosis documentation by primary care physicians. To facilitate this assessment, we are using a large database of Ontario EMR records called the Electronic Medical Record Administrative data Linked Database (EMRALD) [10-12]. At the time of this study, EMRALD contained data from 296 family physicians at 31 practices who use Practice Solutions® EMR and is located at the Institute for Clinical and Evaluative Sciences in Toronto, Ontario. Records in EMRALD include comprehensive electronic patient records, consult notes, as well as diagnostic imaging and lab test results for more than 300,000 individual patients. The distribution of patients represented in EMRALD reflects the age and sex distributions of the province and the average duration of EMR usage by participating clinics was 4 years. Analysis based on EMRALD data therefore can be expected to represent relatively recent usage trends.

The specific research objectives of the present study are:

First, to assess the completeness of BMD exam capture in EMRs and the potential for exam results in the EMR to yield gold-standard diagnoses of osteoporosis based on collected BMD T-scores. To assess the completeness of exam capture, we relate BMD results in EMRALD for all patients over 40 to BMD exam billings in a provincial insurance database (OHIP). We also explore the number of tests that are stored in the EMR as text, and where machine-assisted identification of BMD T-scores can be expected to be relatively straightforward.

Second, to assess the relationship between the information about osteoporosis found in BMD results and osteoporosis information found elsewhere in patient charts. For this level of analysis, we manually reviewed 7500 randomly selected patient records in EMRALD to determine where and how osteoporosis information was coded across the sample.

Third, to explore the information that EMRALD may hold about screening for osteoporosis within primary practice and after fragility fracture. Analysis here focuses on the charts of 151 individuals who were identified in the subset of 7500 as fragility fracture patients. We explore the incidence of BMD screening in this group and characterize other information indicative of osteoporosis in the population.

Methods

Data Collection

To construct EMRALD, clinically relevant data fields from the EMRs of participating family physicians are extracted through a custom software 'plug-in' and securely transferred to ICES. Data are collected from each clinic every 6 months. At ICES, health card numbers for provincial insurance are partitioned from data and the remaining data undergoes de-identification as per standard ICES policies and procedures for maintaining privacy and confidentiality[13].

The research protocol was approved by the Research Ethics Board of the Sunnybrook Health Sciences Centre.

Completeness of BMD Exam Capture

To assess the completeness of EMRALD's capture of BMD exams, BMD results in EMRALD for all patients over 40 were related to billing records for BMD exams in OHIP.

To begin, records for all patients over age 40 as of December 31, 2011 were selected from EMRALD. The diagnostic imaging results for these patients were searched and exams that were both labeled 'BMD' and dated between December of 2011 and January of 2006 were recorded.

For the same group of patients, OHIP billing records were searched for BMD exam billings dated before the end of 2011 and after either January 1, 2006 or the date the patient first appeared in EMRALD (whichever was more recent). Of note is the fact that new fee codes for baseline BMD exams were introduced by OHIP in 2008. This means that exams in EMRALD dated after 2008 were matched with a slightly different set of OHIP billings than exams dated prior to 2008 (refer to Table 3 for OHIP billing codes).

To relate OHIP records to EMR records of BMD examination, bi-directional matches were performed. First, an attempt was made to pair each OHIP billing with a BMD exam in EMRALD that shared the *exact same date*. Because exams may appear in EMRALD several days post-billing to OHIP, a second attempt was also made to match OHIP billings with corresponding exams in EMRALD that were dated *up to 30 days after billings took place.* In the opposite direction, BMD exams found in EMRALD were paired with OHIP billings sharing the *same date* and also with billings that took place *up to 30 days prior* to the exam date recorded in EMRALD.

We report the number of tests located in both EMRALD and OHIP for the patients and the percentage of tests that could be matched between corresponding data sources. We also report the number of BMD tests that were stored in EMRALD in text format rather than as images, in an effort to gauge the potential to access numeric T-scores using computerized searches. Entries for BMD exams in EMRALD that were more than 200 characters in length or which contained instances of the word "T-score" were flagged as accessible.

Relationship Between BMD Results and Other Osteoporosis Information

To assess the relationship between BMD results and osteoporosis information found elsewhere in patient records, 7500 charts for individuals over age 20 were randomly selected from the database and manually reviewed by a trained nurse. Details regarding osteoporosis were abstracted from the machine-readable, structured portions of electronic records; these include patient profiles, notes from individual patient encounters, text-based (but not image-based) diagnostic imaging results, consult notes and lab tests. During abstraction, both content and location of pertinent information in the electronic charts were noted. Information that was abstracted included:

1. Basic Demographic Information, including the age and sex of patients;
2. Evidence of osteoporosis as documented in:
    a. BMD exam results;
    b. Patient summaries (e.g., in problem lists);
    c. Notes attached to individual patient exams (such as annual exams);
    d. Consult notes (e.g., hospital discharge notes, ER consult notes, notes from specialists);
    e. Other exam results (e.g., X-ray investigations).

Documentation that was considered indicative of osteoporosis included presence of BMD T-scores of the femoral neck or lumbar spine below -2.5, vertebral compression fracture as documented by x-ray investigation, documentation of osteoporosis in the patient profile, or a diagnosis attached to a patient exam, given in a consult note or on an imaging result. We report the number of patients identified as osteoporotic in the sample, and the distribution of osteoporosis documentation across the sample.

Documentation of Osteoporosis among Post-Fracture Patients

Current guidelines recommend that all patients who have undergone a recent fragility fracture should be screened for osteoporosis; the gold standard for diagnosis of osteoporosis is based on the result of a BMD examination[2].

To explore consideration of osteoporosis among fragility fracture patients, the subset of 7500 records described above was additionally reviewed for fragility fracture evidence. Evidence that was considered indicative of a fracture history included radiological evidence of fracture (X-rays, CT scans, etcetera),

documentation of a fracture in patient profiles, hospital discharge notes, or mentions of fractures in consult notes from specialists. If fractures were specifically indicated as “fragility fractures” in charts, this was noted. Fractures of the head, foot, toe, hand and finger were excluded from analysis.

We report the number of patients identified as having a history of fracture in the sample, the number with specific mention of “fragility fractures”, and the percentage of fragility fractures patients for whom there is evidence to suggest consideration of, or screening for, osteoporosis.

Results

Completeness of BMD Exam Capture

Records for 79,740 patients over age 40 were located in EMRALD.

OHIP billing records indicated that 14,536 of these individuals had one or more BMD tests after their appearance in EMRALD, resulting in a total of 20,174 OHIP billings for BMD tests, or 1.39 billings per patient (on average) between 2006 and 2011. A summary of the BMD tests as recorded by the OHIP billing database is presented in Table 1.

Table 1. Distribution of BMD billings in OHIP for EMRALD patients over age 40.

OHIP Fee Codes	**Fee Code Description**	**# (%)**
X146*, X145*	Baseline BMD test	1996 (9.9%)
X152, X153	Second BMD test, low risk patient	5250 (26.0%)
X142, X148	Subsequent BMD test, low risk patient	75 (0.4%)
X149, X145	Subsequent BMD test, high risk patient	12,853 (63.7%)
Total billings for tests		**20,174 (100%)**

**indicates a fee code that was added in 2008.*

Of the 20,174 BMD tests that were identified in OHIP, 89.8% could be matched with a corresponding test in EMRALD that shared the exact same date. When matching constraints were relaxed to allow for correspondences between billings and exams in EMRALD dated up to 30 days post-billing, the match rate increased to 97.9%.

In EMRALD, a total of 21,553 BMD exams were located for 15,365 patients, resulting in an average of 1.4 BMD tests per patient between 2006 and 2011. Of these tests, 84.1% could be matched with an OHIP billing that shared the exact same date. Using relaxed matching constraints (i.e., when allowing matches with billings prior to EMR dates), the match rate increased to 91.7%. 829 patients with BMD tests in EMRALD (5.4% of all patients with BMD tests in EMRALD) were found to have no corresponding billings for BMD tests in OHIP.

A total of 72.6% of the BMD tests in EMRALD were stored as text and 66.5% contained the word ‘T-score’ specifically. However, the number of BMD tests stored as text varied widely from practice to practice. The mean percentage of tests stored as text at each clinic was 65% with a standard deviation over 35% and a range that spanned 0% to 100%.

Relationship Between BMD Results and Other Osteoporosis Information

The randomly selected group of 7500 electronic records represented a group of patients with a mean age of 49.6 years, 57.3% of whom were female.

A total of 441 charts (5.9% of the total) were found to contain evidence of osteoporosis. The average age of the patients in the group with osteoporosis was 71.0 years, and 87.3% were female. By far the most common way of documenting osteoporosis was in the context of individual patient exam entries (such as in

an entry for a recent annual exams). A total of 398 cases of osteoporosis, or 90.2% of the total, were documented this way. Only 246 charts, or 55.8% of the osteoporotic group, were found to have evidence of osteoporosis that was substantiated with results from BMD exams. A total of 277 (or 62.8% of the group) contained a diagnosis of osteoporosis in an electronic patient profile.

Results are summarized in Table 2.

Table 2. Documentation of patients with osteoporosis (n = 441)

Documentation found in:	**# (%)**
Notes for Patient Exam(s)	398 (90.2%)
Patient Profiles	277 (62.8%)
BMD Exam Result	246 (55.8%)
Consultation Note (Specialist Consult Note, Emergency Consult Note, etc.)	38 (8.6%)

Documentation of Osteoporosis among Post-Fracture Patients

A total of 1473 fractures were documented in the charts; these were found in the charts of 1048 individual patients (15.9% of the sample). Charts for 151 of these individuals *specifically* mentioned a history of low-trauma fracture; these patients were therefore labeled "fragility fracture" patients. Of these patients, no record of BMD investigation could be located for 55, or 36.4% of the group. For several of these patients, however, alternative evidence was located to indicate consideration of osteoporosis (i.e. notes in patient profiles, consult notes, etcetera). There were a total of 36 fracture patients (23.8% of all fragility fracture patients) for whom no evidence of osteoporosis consideration could be located (i.e. no BMD results or other charted notes).

Results are summarized in Table 3.

Table 3. Osteoporosis documentation among patients with fragility fractures

	# (%)
Patients with fragility fracture	151 (100%)
Fragility fracture patients without evidence of BMD investigation	55 (36.4%)
Fragility fracture patients without evidence of OP investigation	36 (23.8%)

Discussion

Completeness of BMD Exam Capture

The present study indicates that EMR records capture BMD results completely relative to administrative data sources, and that the information required for 'gold-standard' diagnosis of osteoporosis is readily accessible to machine-assisted interpretation in a significant proportion of these results.

In a 2005 study of osteoporosis information in EMRs, a relative shortage of BMD tests was found across the EMR records for 78 practices[9]. In that prior work, only two practices could be located with more than 200 BMD test records on file[9]. Our study of data from 31 clinics, by contrast, identified several comparable practices averaging more than 200 BMD tests over similar stretches of time. More importantly, our results indicate that EMRALD captures BMD exams found in the OHIP database, which are the majority of those that take place in the province. In addition, EMRALD was found to capture records of some BMD tests that do *not* appear in OHIP billing records. Errors in test categorization and a lack of perfect synchronization between the EMR and OHIP may account for some of these extra tests, but EMRALD likely captures additional valid test results, such as those for tests performed outside of Ontario or billed to alternate insurers.

This evidence suggests that key details regarding BMD tests are reliably being provided to and/or labeled in Ontario's EMRs. The fact that 97% of OHIP billings for BMD tests could be matched with exam data in EMRALD contrasts with recent analyses of EMRALD's capture of laboratory tests and prescription information; roughly 67% of EMRALD's data could be matched with administrative records for these services[4]. BMD exams are, however, somewhat unusual in that they are typically ordered directly by family physicians while other imaging and laboratory services (like x-rays) may be ordered by specialists. Increasing comfort with EMRs on the part of clinicians and improvements in interfaces between EMRs and diagnostic imaging labs are likely contributors to the BMD exam coverage in EMRALD. According to the National Physician Survey, in 2010, 40% of family physicians in Ontario reported an electronic interface to diagnostic imaging services and this percentage is climbing[5].

In the 2005 study, moreover, BMD exams could not be associated with the numeric T-scores required for diagnosis of osteoporosis[9]. Results from our study, however, indicate T-scores to be somewhat more accessible, as the word 'T-score' could be automatically drawn from more than 65% of EMRALD's entries for BMD exams. Promising related work has taken additional steps toward automated BMD exam result interpretation: in a study of EMR records for post-menopausal female veterans from the U.S., T-scores were not only pulled from 63% of the exams stored in an EMR but were correctly associated with regions of interest and diagnoses more than 80% of the time[14]. Like the 2005 study, however, the present study documents variation of T-score accessibility by practice. The percentage of BMD reports stored as images rather than text at each practice ranged the entire spectrum (from 0 to 100%).

In summary, EMRALD was found to record incidence of BMD testing comprehensively relative to administrative data; accessibility of the T-scores in test results means that EMRALD may soon be able to contribute to the estimation of key health status indicators in the Canadian population, including prevalence of both BMD test outcomes and osteoporosis[15]. Related research to validate the Canadian Association of Radiologists and Osteoporosis Canada guidelines in the Canadian population required BMD data from roughly 4,000 Manitoban patients per year (or 16,000 patients across 4 years)[16]. The size of population accessible to diagnosis of osteoporosis via BMD results in EMRALD is slightly smaller but comparable.

Relationship Between BMD Results and Other Osteoporosis Information

While BMD results were captured completely by EMRALD, they were not found in all charts of patients with a diagnosis of osteoporosis. By far the most common way in which osteoporosis was documented was in the notes for individual patient exams, like annual exams. About 63% of the time osteoporosis information was found in patient profiles and only about 56% of the time the diagnosis was substantiated with a BMD result.

This is not a surprising result, as some patient charts in EMRALD span a relatively short period of time. Many individuals were likely investigated for osteoporosis prior to their appearance in EMRALD; results substantiating their diagnosis may not be available to the EMR in electronic form. The BMD records in EMRALD, then, may potentially identify osteoporotic individuals with sensitivity, but not with specificity. As EMR usage continues, however, it will most likely capture more of the BMD information required to substantiate those diagnoses of osteoporosis that are on file.

The fact that entries for individual exams proved to be the most common form of osteoporosis documentation is somewhat troubling, perhaps, as notes from individual patient exams tend to become buried over time[17]. Patient summaries, by contrast, were specifically designed to hold persistent clinical information in an accessible fashion and have recognized potential to facilitate coordination of care related to chronic conditions[17]. However, osteoporosis diagnoses were found in this location only 63% of the time.

Documentation of Osteoporosis among Post-Fracture Patients

In the 2005 study of osteoporosis and fracture information in EMR records, few if any fragility fractures were identified[9]. In this study, by contrast, a significant number of fractures were identified but less than 15% could reliably be identified as fragility fractures.

In the present study, 36 of those individuals identified as fracture patients were found to have no documented consideration of osteoporosis in their charts; documentation was defined to include BMD test results and other clinical notes. This is somewhat concerning as currently guidelines state that all fracture patients should be screened for osteoporosis; those without a history of BMD testing should receive a BMD test[2]. However, the result is consistent with evidence that suggests fragility fracture patients are inadequately screened in general. In a 2005 review of osteoporosis management after fracture, for example, less than 50% of patients with fragility fractures followed up with a doctor and investigations for osteoporosis were performed in less than 15% of the group[18]. In a more recent analysis of Ontario's BMD testing rates, less than 20% of fragility fracture patients received a BMD test within 6 months of their fracture[4].

These prior results, however, were not specific to patients in the care of a family physician and of known fracture status. The fact that the current study focuses on a specific care pathway may partly account for the high proportion of fracture patients in EMRALD with records of BMD testing (63.5%) relative to the proportion reported for the Ontario population[4]. Moreover, evidence tells us that testing rates for this population and within this care pathway can be altered using electronic reminders. A 2006 study of fracture patients identified using HMO billings found 40% were tested at six months post-fracture when family physicians received electronic reminders; without reminders testing rates were under 2%[19]. The population focus in the current study, however, focuses on fractures known to family physicians, known to be low-trauma, and identified based on annotations within EMR records.

Limitations

There are several limitations to the current study. For one, while we know that BMD capture in EMRALD records is complete, we do not know the accuracy of any other information about osteoporosis or fracture. Documentation of fractures in the EMR records is particularly problematic, as fragility fractures can be very difficult to characterize. Vertebral fractures, for example, may be difficult to determine given both the lack of fracture recognition by clinicians and the ambiguous terminology in radiology reports[20]. Doctors and patients may also note fractures less forcefully and frequently, as they are transient conditions[21]. Many fragility fractures found in administrative data may therefore be missing from EMRALD records. It seems relatively probable, however, that those fractures specifically noted in EMRALD as "fragility fractures" are indeed the result of low-impact events.

EMRALD's documentation of fragility fractures is also limited in that it often excludes specific fracture dates. History of fracture is sometimes noted in patients' problem lists, for example; dates provided here may be vague or in the relatively distant past. This limits our ability to determine if BMD exams were ordered after a given fracture as guidelines recommend. Direct validation of the fractures documented in EMRALD against administrative data sources, like emergency room records and physician billings, is subject for future research; this will include validation of fracture dates.

In addition, some patients may have been screened for osteoporosis at clinics not represented in EMRALD or at times prior to the commencement of their EMR record such that these BMD results may not be present in EMRALD as a result. This is likely why many diagnoses could not be substantiated by a corresponding BMD result, despite the fact that EMRALD's coverage of BMD results after 2006 is complete.

Finally, the sample of EMR records in EMRALD only reflects practices that make use of a single EMR system (Practice Solutions); results from EMRALD may therefore not generalize to data from other EMR databases. However, EMRALD has been shown to accurately capture the presence of other medical conditions in a way that reflects province-wide rates[22].

Despite these limitations, EMRALD remains a promising source of information about osteoporosis and fracture in the Ontario population, and it holds the potential to contribute to the estimation of important health status indicators. Coverage of BMD results, in particular, is significantly more complete than it appeared to be in 2005 and T-scores required for diagnosis are accessible to machine assisted interpretation

in a significant proportion of these. Moreover, data in EMR charts may shed light on key osteoporosis management indicators in the context of primary care. Results presented here, for example, demonstrate the EMR records to contain information about screening for osteoporosis among fracture patients and on the part of family physicians.

Abstract

While potential medication-to-medication interaction alerting engines exist in many clinical applications, few systems exist to automatically alert on potential medication to herbal supplement interactions. We have developed a preliminary knowledge base and rules alerting engine that detects 259 potential interactions between 9 supplements, 62 cardiac medications, and 19 drug classes. The rules engine takes into consideration 12 patient risk factors and 30 interaction warning signs to help determine which of three different alert levels to categorize each potential interaction. A formative evaluation was conducted with two clinicians to set initial thresholds for each alert level. Additional work is planned add more supplement interactions, risk factors, and warning signs as well as to continue to set and adjust the inputs and thresholds for each potential interaction.

Introduction

Complementary and alternative medicine (CAM) refers to a group of therapies not usually practiced in conventional medicine. The National Institutes of Health (NIH) outlines categories of CAM including natural products (dietary supplements or probiotics), mind and body medicine (meditation, yoga, or acupuncture), manipulative and body-based practices (spinal manipulation, massage therapy), and other practices (traditional healers, traditional Chinese medicine, and other modalities).[1] CAM practices are not typically taught in medical schools and are not readily available in hospitals. Despite this, CAM usage is prevalent in the United States. Up to 40% of Americans use health care therapies considered outside of conventional medicine.[2] In some cases, clinical practice guidelines recommend CAM therapies in addition to conventional medicine. The American College of Cardiology Clinical Expert Consensus Guidelines on Integrating Complementary Medicine Into Cardiovascular Medicine (2005) recommend meditation, biofeedback, Omega-3 fatty acids, stanol/sterol ester margarines, and soy proteins as possible integrative CAM therapies in patients with cardiovascular diseases.[3]

While many CAM practices are considered safe (e.g. meditation, biofeedback), some dietary supplements may interact with conventional pharmacologic therapies, or with the disease state itself, and negatively impact patient outcomes. For example, clinical trials evaluating high dose vitamins (vitamin C > 2,000 mg/day; vitamin E > 1,000 mg/day), oleander, ephedra, and other herbs/botanicals with stimulant properties demonstrate adverse effects in patients with cardiovascular diseases.[3] Ginseng and St. John's Wort are herbal agents known to interact with cardiovascular drug therapies such as digoxin or warfarin.[4-6] Based on the clinical evidence available, CAM therapies should be used with caution in patients with cardiovascular diseases.

Despite the safety concerns, most patients do not discuss CAM use with their providers. Our prior study reported a large discrepancy between self-reported and provider-perceived usage-rate.[7] Lack of communication and documentation of CAM therapies make it difficult for clinicians to assess and mitigate the risk of herb-drug-disease interactions.[8] In addition, literature suggests both providers and consumers lack knowledge of the safety and efficacy of herbal medicine.

Our general goal is to alert physicians and patients of potential herb-drug interactions. Many automated alert systems tracking prescription drug-drug and drug-disease interactions are widely available and highly utilized in pharmacies and clinics. Indeed, automated alerts are one of the best-known and most successful examples of computer-based decision support.[9, 10] However, there is a need for an automated system which educates and alerts physicians and patients of the safety concerns regarding CAM therapies and herb-drug-disease interactions.

This paper describes a prototype herb-drug interaction alert system that we have developed. A formative evaluation was performed using data from the Veterans Health Administration's Electronic Health Record (EHR).

System Overview

The alert system consists of several key components: a module that looks for potential medication and supplement interactions based on medication or medication class, modules that calculate weights of various risk factors and warning signs, and a module that determines what level of alert should be given for each potential interaction. Data on herb/drug use, risk factor, warning signs may be obtained from an EHR or patients directly. Alerts may be provided to the users directly or delivered electronically (e.g. through email).

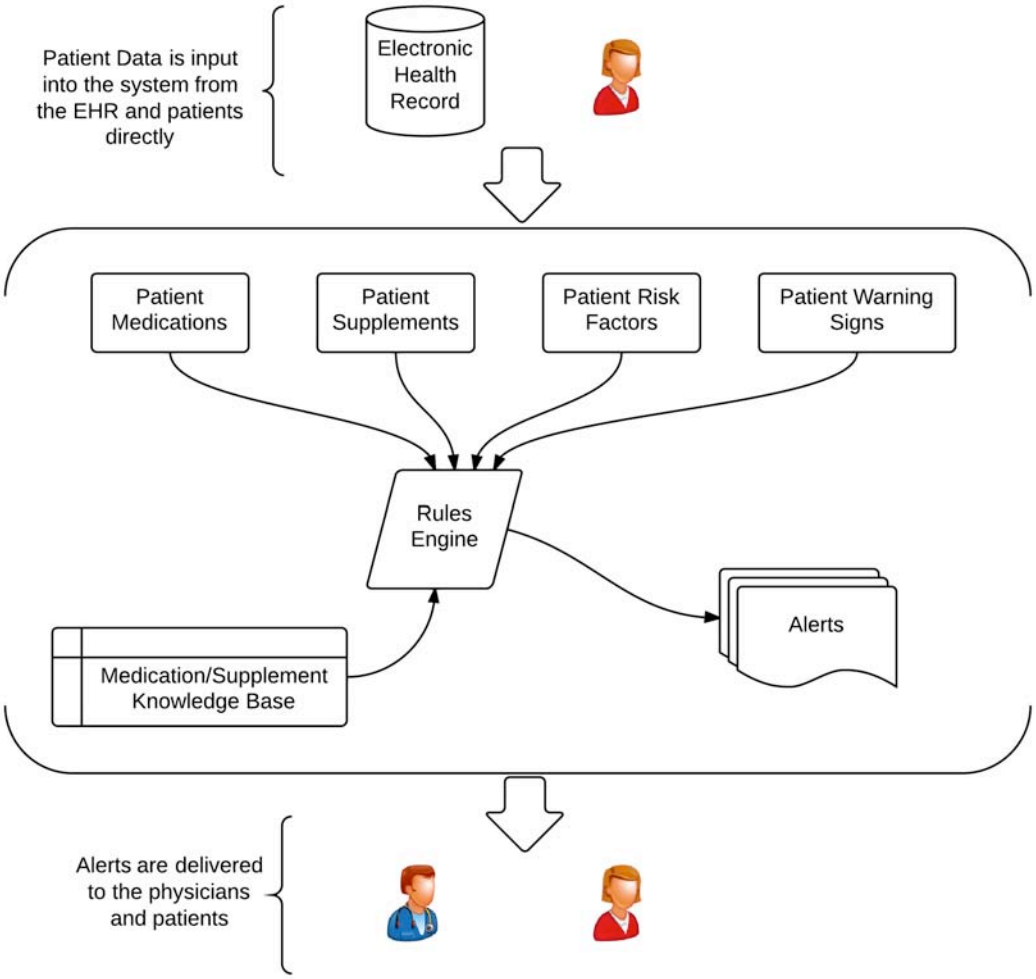

Figure 1. Knowledge base architecture.

Knowledge Base

A clinical pharmacist with expertise in drug information and drug utilization review and an informaticist software engineer developed the drug herb knowledge rules. To focus on common and important herb-drug interactions, nine of the most popular US supplements were identified. We assessed their potential interactions with common medications taken by cardiac patients at the University of Utah Health Sciences Center (Table 1). The nine herbal (non-vitamin, non-mineral) agents were identified, based on the National Health Statistics Report of Complementary and Alternative Medicine Use Among Adults and Children (US, 2007)[2] and the Herbal Gram[13]. Using the Natural Medicines Comprehensive Database (NMCD), current therapeutic guidelines, and available clinical evidence, a list

of potential herb-drug interactions was compiled and weighted based on both the likelihood and the severity of the interaction. Likelihood of interaction was determined by the strength of evidence available for the interaction (anecdotal vs. case reports vs. clinical trials, etc.) and severity was determined by the seriousness of the potential interaction as defined by the NMCD. The Natural Medicines Comprehensive Database is a compendium of information on over 1000 herbs and supplements and is based on clinical literature and details not only background information but potential herb-medication interactions. Other clinical evidence considered was based on primary literature.

Table 1. Herbal Agents and Medications Included in the Herb-Drug Interaction Database

Supplements	Medications		
Echinacea	amiodarone	Flecainide	nifedipine
Garlic	amlodipine	fluoxetine	omeprazole
Ginkgo	aspirin	fondaparinux	pantoprazole
Ginseng	atorvastatin	gemfibrozil	paroxetine
Grape seed	carvedilol	glipizide	prasugrel
Green tea	cilastazol	glyburide	pravastatin
Milk thistle	citalopram	hydrochlorothiazide	prazosin
Saw palmetto	clopidogrel	insulin aspart	propafenone
Soy	dabigitran	insulin glargine	propanolol
	dipyridamole	insulin lispro	ranitidine
	ditiazem	insulin regular	rivaroxaban
	dofetilide	irbesartan	rosuvastatin
	doxazosin	lansoprazole	sertraline
	dronedarone	losartan	simvastatin
	enoxaparin	lovastatin	tamsulosin
	ephedrine	metformin	ticagrelor
	eplerenone	metoprolol	torsemide
	escitalopram	mexiletine	valsartan
	esomeprazole	nebivolol	verapamil
	famotidine	nicardipine	warfarin

We took both pharmacokinetic and pharmacodynamic parameters into consideration when developing the knowledge base. For example, pharmacokinetic interactions occur if the absorption, distribution, metabolism, or elimination of a drug is affected. Most often, isoenzymes of the cytochrome P450 system are involved in pharmacokinetic interactions and may result in increased or decreased serum drug concentrations (SDCs) of the affected drug. This may then result in supratherapeutic or subtherapeutic drug effects. Pharmacodynamic interactions involve additive or oppositional pharmacologic effects. For instance bleeding may occur when two antiplatelet drugs are combined. However, decreased efficacy of an antihypertensive agent may occur when combined with a supplement that may increase blood pressure. In addition, using clinical evidence, patient-specific diagnoses and comorbidities which put the patient at higher risk for developing an herb-drug interaction were identified and used to generate personalized alerts.

To help determine the level of alerts for specific patients, risk factors and warnings of the potential interactions were identified. The risk factors and warnings are patient features that potentially increase the likelihood or severity of an interaction or increase the urgency of intervention. Table 2 lists risk factors and warnings in the system. Risk factors and warning signs can be assigned to all potential interactions, or specific interactions by drug or drug class.

Thresholds were set for each interaction based on the total score possible (including risk factors and warning signs) and likelihood/severity of the interaction.

Data was extracted from the Electronic Health Records (EHR) of patients who receive care at the Veterans Administration (VA) Medical Centers. Patients receiving one or more of the nine identified herbal agents along with one or more of the identified prescription medications were considered for inclusion. Herbal agents and prescription medications found via a text search in either the active VA drug list or in a clinic note were used. Patient-specific diagnoses and comorbidities identified as risk factors and warning signs for a drug-herb-disease interaction were defined by International Classification of Diseases (ICD-9) codes reported in the EMR. Risk factors and warning signs were selected based on clinical information gathered from the NMCD, clinical practice guidelines, and primary literature.

Table 2. Risk Factors and Warning Signs Used for Calculation of Personalized Alerts

Risk Factors	Warning Signs	
>3 comorbidities	Arrhythmia	Hypotension
>5 meds/day	Bleeding	Increased LFTs
Age >65	Bradycardia	Lactic acidosis
Arrhythmia	Bruising	Lethargy
Heart failure	Diarrhea	Myopathy
History of GI bleed	Dizziness	Orthostatic hypotension
Impaired hepatic function	Edema	QT prolongation
Impaired renal function	Electrolyte imbalance	Renal failure
Multiple QT prolongation medicines	Epistaxis	Rhabdomyolysis
Multiple serotonergic medicines	GI hemorrhage	Serotonin syndrome
Patient history of MI	Hearing loss	Signs of drug inefficacy
Recent stroke	Hyperkalemia	Somnolence
	Hypertension	Syncope
	Hypoglycemia	Tachycardia
	Hypokalemia	Thrombosis

Alert Generation

Nine herbal agents and 62 medications were selected for inclusion in the herb-drug database. Overall, 259 drug-herb-disease rules were built into the system.

Drug-herb-disease interactions identified by the new system were assigned one of three severity alert ratings: 3) Most Serious, Action Recommended; 2) Less or Moderately Serious (or “Monitor” and Action Should be Considered); and 1) Least Serious (No specific action is recommended but education is provided so that the clinician and patient can be aware of a potential interaction).

Formative Study

To test the alert system, verify thresholds, and inform further development, we manually extracted patient characteristics from the VA VINCI Database (http://www.hsrd.research.va.gov/for_researchers/vinci/). To identify patients with potential interaction, a computer query was first performed on all VA clinical notes for the nine herbal supplements described above. The text search was limited to the Active VA and Non VA Medication List section that is embedded in various VA notes such as Pharmacy Encounter Notes, Anticoagulant Clinic Notes, Clinic Notes, etc. We then searched the structured medication orders within the 30 day window of the documentation of herbal usage for medications with potential interaction. Twenty patients with potential interactions were randomly selected

for the initial formative evaluation. Potentially relevant patient characteristics such as age, gender and clinical diagnoses (based on ICD codes) were extracted.

A practicing cardiologist and a clinical pharmacist with expertise in herbal medicine were asked to evaluate the 20 patients cases for potential interactions. Without knowledge of the automated rules, they identified and evaluated all potentially harmful herb-drug interactions, risk factors, and warning signs for the alert as well as the level of severity for the alert. These expert-generated alerts were then compared to the automated herb-drug alerts.

Results

A total of 622 subjects taking at least one herbal agent were identified by the automated system. Twenty subjects with a total of 26 herb-drug interactions were randomly selected for evaluation (Table 3). The mean age of subjects was 68 years (range 51-85). All subjects were male. The mean interaction scores calculated by the herb-drug interaction database were 5.3 resulting in 11 Level one alerts, 10 Level two alerts and 5 Level three alerts. A Pearson's coefficient of 0.78 was calculated between the automated alert levels and the expert alert levels.

All 26 automated alerts generated by the system were deemed appropriate by the clinicians, i.e. excellent positive predictive value. During the manual review, the clinical team also identified 3 additional herb-drug interactions not originally identified by the automated system (Table 3). The missing alerts were due to lack of related rules. The team also identified 4 additional risk factors deemed important for identification and evaluation of the severity of the potential herb-drug interaction including: poly-herb use, smoking history, alcohol use and a dementia diagnosis. The expert-generated alerts produced 10 Level one alerts (34.5%), 15 Level two alerts (51.7%) and 4 Level three alerts (13.8%). Per clinician review, herb-drug combinations that were associated with a possible risk of hypoglycemia generated higher level alerts.

Overall, 15 unique herb-drug interactions were included in the analysis (Table 3). In this study of 20 patients, pharmacodynamic herb-drug-disease interactions were identified more frequently than pharmacokinetic herb-drug interactions (93.1% vs. 6.9%). The most frequently identified interaction was concurrent administration of the herb saw palmetto and an antiplatelet agent with the potential for a pharmacodynamic interaction resulting in an increased risk of bleeding (34.5%; n = 10). The second most frequently identified interaction pair was garlic with an anticoagulant or antiplatelet agent and a potential pharmacodynamic interaction associated with increased risk for bleeding (27.6%; n = 8). The most frequently identified risk factors based on medication lists and ICD-9 codes reported in the active problem list of the clinic note for the patent were > 5 medications (95%; n = 19) and age greater than 65 (60%; n = 12).

Table 3. Summary of Study Patients

Patient Number	Age	Number of Risk Factors	Herb/Supplement	Drug	Pharmaco-dynamic Interaction	CYP450 Interaction	Risk Score	Automated Alert Level	Expert-Based Alert Level
1	70-74	2	Saw Palmetto	Warfarin	X		6	2	2
2	50-54	1	Ginkgo Biloba	Sulfonylurea	X		5	3	3
2	50-54	1	Ginkgo Biloba	Metformin	X		5	2	2
3	70-74	2	Saw Palmetto	Aspirin	X		6	1	1
4	70-74	2	Garlic	Clopidogrel	X		6	3	3

Key: *=additional alerts identified during expert-generated validation process

Discussion

This study demonstrates the feasibility of extracting data from the VA VINCI Database to clinically assess herb-drug-disease interactions. This was the first iteration of the development of an herb-drug-disease interaction knowledge base which is useful for personalized, automated alerts. The initial qualitative assessment demonstrates the complexity of identifying and evaluating potential herb-drug interactions in an EHR. In 20 selected patients, a total of 29 expert-generated herb-drug alerts were generated. Both pharmacodynamic and pharmacokinetic interactions were identified. The range of the severity of the alerts varied based on risk factors and warning signs present in the patients' EHR. The most frequently reported alert severity was a Level 2 or Moderately Serious alert ("Monitor," and Action Should be Considered). The least frequently reported alert severity was a Level 3 or Most Serious alert (Action Recommended). This is appropriate to mitigate alert-fatigue and is in line with current clinical evidence for the likelihood and severity of potential herb-drug-disease interactions.

When the clinical team met to identify and rate the severity of the herb-drug interactions, several issues emerged that warrant further evaluation and possible inclusion as additional risk factors. One risk factor that was identified was whether the patient was on five or more daily medications. However in examining patient profiles it was apparent that some patients were often using more than one herb or supplement. Thus poly-herb or poly-supplement combinations should be considered. Also, some patients were identified as smokers and since this may increase the risk for thromboembolic events this may be another important consideration. Furthermore, alcohol use may increase risk for hemorrhagic events, such as gastrointestinal bleeds, as well as hypoglycemic events, since alcohol use inhibits gluconeogenesis. Hence that may warrant inclusion as additional risk factors. Mention of memory impairment or early dementia should also be considered for risk factor inclusion since this may affect medication use behavior. Finally, codes for strokes should be clarified to determine if the event was ischemic or hemorrhagic since those are two different outcomes that could be part of the herb-drug interaction profile.

In future iterations of the system design, we will refine the rules engine formulas to improve data acquisition to gain a more comprehensive list of herb-drug interactions and include additional clinical data for identification of potential risk factors and warning signs. We will also customize the alert content based on intended recipient (physician, nurse or patient). We will continue to update the knowledge base based on new information on interactions from the literature. For example, clinical information regarding the hypoglycemic effects of many herbal agents (milk thistle, garlic, etc.) is becoming available and should be considered for inclusion in our decision support framework. This study demonstrates feasibility of using EHR data to assess potential herb-drug-disease interactions using a rule-based alerting system. Additional refinement of patient characteristics and interaction rules is needed.

Factors Contributing to CPOE Opiate Allergy Alert Overrides

Deborah Ariosto, PhD, RN
Vanderbilt University Medical Center, Nashville, TN

Context Increasing regulatory incentives to computerize provider order entry (CPOE) and connect stores of unvalidated allergy information with the electronic health record (EHR) has created a perfect storm to overwhelm clinicians with high volumes of low or no value drug allergy alerts. Data sources include the patient and family, non-clinical staff, nurses, physicians and medical record sources. There has been little written on how to collect hypersensitivity information suited for drug allergy alerting. Opiates in particular are a frequently ordered class of drugs that have one of the highest rates of allergy alert override and are often a component of pre-populated Computerized Provider Order Entry (CPOE) order sets. Targeted research is needed to reduce alert volume, increase clinician acceptance, and improve patient safety and comfort.

Design, Setting, and Patients An FY10 retrospective, quantitative analysis of 30321 unique adults with opiate allergies triggering CPOE alerts at a large academic medical center.

Measurements The prevalence of opiates ordered with opiate allergy alerts triggered and overridden is described. The effect of age, race, gender, visit type (medical, procedural), provider type (physician, advance practice nurse), and reaction/severity (e.g. nausea/mild) on the likelihood of provider override of the patient's first opiate alert was analyzed using Generalized Estimating Equations (GEE).

Results Analysis of a patient's first opiate allergy alert (n=2767) showed that only prescriber role had a significant effect on alert override compared with all other variables in the model. Advanced practice nurses (APNs) were generally less likely to override the patient's first opiate alert as compared to physicians (GEE, β=-.793, p=.001). However, override rates remained high, with 80% for APN's and 90% for physicians.

Over half of all discharges had opiates ordered during their stay. Of those, 9.1% of the patients had recorded opiate allergies triggering 25461 CPOE opiate allergy alerts. The largest sub-group of alerts was triggered by gastrointestinal (GI) "allergies" such as nausea and constipation. Removing these types of non-allergic, low severity GI reactions from the alert pool reduced the first alert volume by 15% and the overall alert volume by 22%. Of note is that a history of codeine allergy triggered a significant volume of opiate alerts, yet was rarely ordered.

Conclusion With an increasingly complex, information dependent healthcare culture, clinicians do not have unlimited time and cognitive capacity to interpret and effectively act on high volumes of low value alerts. Drug allergy alerting was one of the earliest and supposedly simplest forms of CPOE clinical decision support (CDS), yet still has unacceptably high override rates. Targeted strategies to exclude GI non-allergic type hypersensitivities, mild overdose, or adverse effects could yield large reductions in overall drug overrides rates. Explicit allergy and severity definitions, staff training, and improved clinical decision support at the point of allergy data input are needed to inform how we process new and re-process historical allergy data.

Introduction

In 2009 President Obama signed into law the Health Information Technology Economic and Clinical Healthcare Act (HITECH), which significantly ramped up the investment in this nation's health care infrastructure by providing significant reimbursement incentives for "meaningful use" of electronic health record (EHR) technology. Computerized provider order entry (CPOE) adoption and drug-allergy checking, were two of the meaningful use objectives described for phase I. With increasing incentives to implement these objectives comes increasing need to mitigate adverse, unintended consequences of this evolving technology.

While there is evidence to support this safety measure, numerous alert fatigue studies cite the excessive alert volume and low clinical value as significant factors in intentional and unintentional alert overrides (van der Sijs, 2009). Two classes of drugs, antibiotics and opiates, represent the majority of CPOE alerts and alert overrides (Hsieh et al., 2004; Hunteman et al., 2009). This study focused on the latter. Opiates are not usually associated with the life-threatening allergic reactions (i.e. anaphylaxis, angioedema) as are antibiotics. Previous studies have identified that from 31-80% of the patients with opioid/narcotic allergies are labeled inappropriately (Gilbar 2004, Pilzer 1998). Commonly reported are known side effects or mild overdose due to potentiation with other drugs.

The European Academy of Allergy and Clinical Immunology proposed a definition, "Hypersensitivity causes objectively reproducible symptoms or signs, initiated by exposure to a defined stimulus at a dose tolerated by normal subjects" (Johansson I, 2005). It is doubtful that this definition is understood and consistently applied in the medication allergy history by those outside of the allergy field of medicine.

The increase in opiate allergies is likely the by-product of a longitudinal EMR that has moved unconnected, and often unsubstantiated, allergy records into a centralized data repository. It is facilitated by lack of staff education and reinforced by data entry screen design. Many EMRs have an associated data input screen named "Allergy" that was designed to store allergy data, but has expanded to collect any possible adverse drug reaction. The more appropriate term purposed for CPOE is "drug hypersensitivity" which is the umbrella term that includes both allergic (immune system mediated) and non-allergic types of reproducible adverse drug reactions.

Study objectives

The purpose of this study was to identify factors that contribute to high volume, low value alerts that are consistently overridden and which pose minimal patient safety concerns. These low value alerts represent known drug side effects of low/mild severity as well as low/mild hypersensitivities. Opiate alerts represent the most common over-alerting problem in the literature and comfort management is a significant component of clinical care in most settings. Comfort management refers not only to timely and effective pain relief, but management of undesirable opiate side effects such as nausea and constipation. Patient and prescribing provider attributes were also evaluated to determine if factors other than the allergy reaction influenced opiate allergy alerting.

Meaningful Use Stage I was about widespread adoption of the technology. However, the success of subsequent decision support depends heavily upon its ability to deliver trusted, clinically significant, actionable information at the point of care. The following exemplar highlights the need for this study:

> *A patient was urgently admitted and underwent open heart surgery. In recovery, an order was placed for needed pain medication for this intubated, agitated patient. A narcotic was ordered and the CPOE system alerted the provider that the patient was allergic to the ordered class of*

narcotics. Review of the documented allergy history showed an adverse reaction to codeine, but the reaction and severity were not documented. Family was unavailable. Nurse, physician and pharmacist conferred, during which time patient experienced increasing distress. The decision to give morphine was made, the patient was monitored closely, and no adverse response was observed. When questioned prior to discharge, the spouse had told the admission nurse that he "felt funny" after taking cough syrup with codeine a couple of years ago. The patient was discharged, and his electronic allergy history was not updated.

Allergy alerts differ from other types of alerts in that they often depend upon patient recall rather than those that depend on discrete lab values, diagnoses, or known interactions with other drugs. Allergy data is collected by clerical and/or clinical staff across multiple venues (clinic, inpatient, doctor's office) and during care encounters of varied intensity (routine, urgent) from patients or their surrogates (spouse, aide, etc.). This suggests that allergy alerts, while simpler to program, may be more complex to successfully to design and implement than other types of drug alerts.

Setting

The study was conducted, with IRB permission, at a large urban, southeastern academic medical center with approximately 40,000 FY10 adult inpatient discharges. The center has a large biomedical informatics department, and extensive clinical systems development capacity. It has a long history of electronic medical record (StarPanel[tm]) and inpatient CPOE applications (WizOrder[tm] , McKesson/Horizon Expert Orders[tm]). Two internally developed data input applications supplied allergy data which were used in both inpatient and outpatient settings. All allergy data, regardless of originating system is collected by a patient summary service (PSS) application that makes this data available to CPOE and other decision support decisions. The CPOE drug alert logic is commercially supplied by First DataBank, Inc. [tm]

Methods

This was a retrospective, quantitative analysis of 25,461 CPOE opiate allergy alerts across 3,473 discharges (2,767 unique patients). Prevalence of opiate allergy alerts across all FY10 opiate orders was calculated. Descriptives of related attributes included: (1) patient (age, race, sex), (2) prescriber alert override (APN, physician), (3) medical or procedural visit, (4) reaction descriptions (ie. nausea) and (5) severity (mild, moderate, severe). Reaction and associated severity were combined to create a new allergy variable called NALS (Non-Allergic/Low Severity) with three mutually exclusive groups: NALS, Not NALS, and Unknown.

The next step was to extract all opiate orders (n=153,026) from the CPOE orders database in FY10 based on the American Hospital Formulary System (AHFS) opiate class code =28080800. These orders were matched to the MRN to calculate the percentage of discharges with opiates ordered. Of these, physician (82%) and Advance Practice Nurse (15.4%) prescriber roles were retained, excluding orders attributed to other staff (2.6%).

In the third step, the opiate allergy alert response log by prescriber ID was extracted from the CPOE allergy alert dataset. This log recorded whether the prescriber cancelled the order or overrode the alert. The two CPOE alert responses were (1) Override (place order) or (2) Cancel order (accept alert). The reason for override field was available, but was excluded since it was 99% missing.

To reduce the dataset, and minimize the influence of excessive repeating alerts for some patients with long lengths of stay, only the patient's first opiate allergy alert was used in the regression analysis for each patient.

The fourth step was to assign allergy status: allergic vs. non-allergic. Each reaction within each group was evaluated (Table 1). Each patient was assigned to one of the study categories (NALS, Not_NALS, Unknown) using the coded severity and opiate reaction data in the patient allergy file. The following algorithm was used, followed by visual confirmation and assignment to one of the three following:

- Unknown: Both reaction and severity are blank or stated unknown
- NALS (GI): Reaction is nausea, vomiting, constipation, diarrhea, or GI upset and severity is low or unknown
- Not_NALS: Assign everything else to Not_NALS

Table 1 Characteristics of Opiate Reactions by severity and by group

Patients		Reaction	Severity			
#	%		Mild	Moderate	Severe	Unknown
1323	28%	Other	1%	2%	7%	91%
1142	24%	Skin	4%	7%	15%	73%
1046	22%	Gastrointestinal	2%	9%	15%	74%
504	11%	Nervous/Mood	2%	9%	22%	68%
781	16%	Unknown/Blank	0%	0%	0%	99%
4796	100%	All	2.5%	6.5%	16.8%	74.3%

Note. Some patients had more than one reaction

The following is an explanation of how reactions were assigned to or excluded from the non-allergic/low severity (NALS) category.

Skin (24%) - The predominant reaction within the skin category was itching and rash. While there were mild reactions recorded, this group as a class was excluded from the NALS category, since it is difficult to tell if these skin reactions were histamine responses of a pseudo-allergy (NALS), or a true, immune mediated allergic reaction (Not_NALS).

Nervous/Mood (11%) - Those in this category ranged from nervousness, insomnia, confusion, hallucinations, to suicidal ideation. In this group, there were very few coded as mild severity. There were only 2 coded mild reaction types that could have been included in the NALS group (sleepy, headache) – but these were excluded due to low volume compared to the class.

Other Reactions (28%) – The information in this group was difficult to classify by body systems. It was highly variable, and had low volumes in any one category. It also included non-allergy type data such as:

Patient received Narcan in the past (respiratory rescue)
Patient has history of opiate abuse
Patient has liver failure, dose appropriately
Patient allergic to IV morphine, but can tolerate oral

Patient has stomach ulcers, may bleed from NSAIDS

Gastrointestinal (22%) - The predominant reaction in the GI category was nausea and vomiting. Those coded or described within the free text as moderate or severe reactions were assigned to Not_NALS category. Those GI Reactions with mild, unknown, or blank severity were assigned to the NALS group if the descriptions were nausea, vomiting, upset stomach, constipation, diarrhea, or GI upset. The assumption being that if it were more than a mild reaction, it would likely been have recorded. More severe reactions such as bleeding or ulcer (exacerbation) were excluded from NALS.

Results

Four allergies triggered 82% of the opiate allergy alerts: Allergies to Codeine (32%), Morphine (28%), Hydrocodone (11%), and Oxycodone (11%). Table 2 displays the number of discharges with a specific opiate allergy and the number of alerts triggered.

Table 2 Patient Allergies Triggering Alerts

# Allergic	%	Allergy	# Alerts	%
1600	36%	Codeine	8,163	32%
1079	24%	Morphine	7,152	28%
483	11%	Hydrocodone	2,783	11%
427	10%	Oxycodone	2,773	11%
211	5%	Hydromorphone	1,190	5%
147	3%	Tramadol	971	4%
61	1%	Nubain	595	2%
148	3%	NSAID/OTC	541	2%
70	2%	Butorphanol	536	2%
104	2%	Meperidine	306	1%
105	2%	Propoxyphene	239	1%
10	0%	Opioid	88	0%
19	0%	Fentanyl	60	0%
2	0%	Dihydrocodeine	23	0%
2	0%	Oxymorphone	21	0%
11	0%	Other	20	0%
4479	100%		25,461	100%

Note: Some patients may have more than one recorded opiate allergy

Four drugs triggered 96% of opiate alerts: Hydromorphone (34%), Oxycodone (25%), Morphine (19%), and Hydrocodone (18%).

Table 3 Drug Orders Triggering Alerts (all ages)

Drug Order Group	#	%
Hydromorphone	8,599	34%
Oxycodone	6,395	25%
Morphine	4,916	19%
Hydrocodone	4,590	18%
Tramadol	435	2%
Fentanyl	354	1%
Belladonna-opium suppository	82	0%
Acetaminophen w Codeine	34	0%
Meperidine	20	0%
Codeine	16	0%
Propoxyphene (Darvon)	10	0%
Methadone (Dolophine)	10	0%
Total	25,461	100%

Reaction and Severity

Severity (mild, moderate, severe) was missing for 74.3% of the reactions. Of those, 16% had no reaction or severity. Overall, alerts with severity coded or described are 2.5% mild, 6.5% moderate, and 16.8% severe.

Non-Allergic/Low Severity Reactions (NALS)

First alerts were stratified into 3 allergy reaction/severity classes as previously described. Non-allergic/low severity (NALS) GI reactions accounted for 15.4% of the first alerts. The override rate for the patient's first alert for all opiate alerts was 89%. Removing the GI NALS alerts reduced the first alert volume for opiates by 15% (425/2767) but did not significantly change the 89% overall alert override rate.

Influence of patient, prescriber and reaction/severity factors on override

Patient characteristics, reason for admission, prescriber role and reaction/severity group on opiate alert overrides were analyzed . The Generalized Estimating Equations (GEE) procedure (SPSS v20) was used to extend the generalized linear model to allow for analysis of clustering and repeated measurements. Clustering can happen when a physician may treat primarily a specialty population like orthopedics or cancer that may unduly influence outcomes based on opiate use. Repeated measurements over time may reflect the fatigue that occurs when a provider has a lot of alerts over a short period of time. The dependent variable of interest was the override response (yes, no), so a binary logistic model was selected, with "no override" as the reference category. There were 697 providers (89% Physicians, 11% APN) who had from 1-28 first opiate allergy alerts (mode=1, median= 3).

For inpatients of all ages, 53% had opiates ordered (n=153026 orders). Inpatient opiate allergy prevalence was 9.1 % (2767/30321 patients). This number is understated as opiate allergic patients without opiates ordered were not captured. For those with opiate allergy alerts, the mean age was 54 years, 81.2% white and 68.6% female. For all admissions, medical discharges were higher (56%) than procedure related ones (44%). However, for the patient's first visit, procedural admissions were higher (59.8%). This reversal was expected as chronic medical conditions are more likely to have readmissions. Physicians received 91.1% of the first alerts and overrode 90% of them. Advance Practice Nurses (APN) received 15% of the first alerts and overrode 80% of them. A summary of the study sample characteristics for the patients first opiate allergy alert are shown in Table 4 below.

Table 4 First Opiate Allergy Alert Response

			Override = No		Override = Yes	
	N	%	N	%	N	%
All	2767	(100%)	304	(11%)	2463	(89%)

**Significant p=.001* *NALS = Non-Allergic/Low Severity alert*

Summary

Over half of all discharges had opiates ordered during their stay. Of those, patients with recorded opiate allergies (9.1%) triggered 25461 CPOE opiate allergy alerts. The largest sub-group of alerts was triggered by gastrointestinal (GI) "allergies" such as nausea and constipation. Removing non-allergic, low severity GI reactions from the opiate alert pool reduced the first alert volume by 15% and the overall alert volume by 22%.

Opiate allergy override rate was 93% for all admissions and re-admissions. It was 89% for the first admission's alert. In the GEE analyses, provider role was the most significant variable in predicting alert overrides. Advanced practice nurses (APNs) were generally less likely to override the patient's first opiate alert as compared to physicians (GEE, β=-.793, p=.001). However, override rates remained high, with 80% for APN's and 90% for physicians. Other factors were not statistically significant in predicting override.

The study revealed two related phenomena in the evaluation of patient opiate allergy alerts. The first being that there was a high prevalence of opiate allergies recorded and alerted on for a reportedly rare occurrence. Particularly problematic were recalled allergies to codeine, which trigger alerts to any opiate order. Findings suggest that this is due, in part, from inappropriately broad allergy definitions and use of the allergy data collection field to alert the prescriber to other non-allergy clinical concerns.

The second was the high volume of common opiate side effects recorded as allergic reactions. Of particular importance was the high volume of overridden opiate allergy alerts triggered by non-allergic/low severity gastrointestinal reactions. Eliminating this group of triggers, would have resulted in a 9% reduction in opiate allergy alerts at the study site. It also opens for discussion that proactive management of drug side effects may be needed.

In this study, 16% of the opiate alerts had no reaction documented, and 74.3% of the alerts had no severity assigned. The absence of reaction detail has been identified as a significant hindrance in provider evaluation of alerts. Data intake screens must be designed to make it easier to capture accurate data, rather than "guess" or ignore these data fields.

This study has several limitations. The data is from a university medical center with advanced capacity to build and continuously tune its CPOE system. The alert trajectory is complex and involves many systems and disciplines which may differ across institutions. Those systems include the allergy data collection tools, allergy processing algorithms, and CPOE alert displays. Limiting the study to opiates may limit its generalizability to other drugs.

Discussion

Drug allergy alerting was one of the earliest and supposedly simplest forms of CPOE CDS, yet still has unacceptably high override rates. While alert logic may be simple, the complex environment in which it exists is not. This study highlights unintended consequences that can occur when computerized clinical decision support logic is not tightly aligned with the electronic medical record data upon which it depends. Much of our recorded healthcare data is influenced by human factors such as memory, personal experience, and varied interpretation by patients, clinicians and support staff.

The volume of side effects, recorded as allergies, should not be ignored or completely attributed to vague allergy definitions, human error or the influences of data entry screen design. Moreover, this

reflects the need for better symptom management of opiates and all medications that are known to cause distressing side effects. Increased education and engagement of patients in understanding the use and effects of opiates, accurate reporting and partnering with their providers in comfort management is fundamental.

This research also highlights the need for continuous feedback and analysis of alerts in clinical practice, to identify opportunities to improve systems and reveal emerging healthcare patterns as more people use computers to record, deliver and improve care. The high use opiates over time may be introducing new hypersensitivities in susceptible individuals that have yet to be fully revealed. More than half of all inpatients had opiates ordered. Of these, 9% of the patients triggered over 25,000 opiate alerts based on how their allergy history was recorded and how often opiates were re-ordered for the visit. This count could be tripled when you consider that the same alert that may be presented to the pharmacist on dispensing, and the nurse on administering.

Application of Bayesian Logistic Regression to Mining Biomedical Data

Viji R. Avali PhD[1], Gregory F. Cooper MD, PhD[1,2,3], and Vanathi Gopalakrishnan PhD[1,2,3]

Abstract

Mining high dimensional biomedical data with existing classifiers is challenging and the predictions are often inaccurate. We investigated the use of Bayesian Logistic Regression (B-LR) for mining such data to predict and classify various disease conditions. The analysis was done on twelve biomedical datasets with binary class variables and the performance of B-LR was compared to those from other popular classifiers on these datasets with 10-fold cross validation using the WEKA data mining toolkit. The statistical significance of the results was analyzed by paired two tailed t-tests and non-parametric Wilcoxon signed-rank tests. We observed overall that B-LR with non-informative Gaussian priors performed on par with other classifiers in terms of accuracy, balanced accuracy and AUC. These results suggest that it is worthwhile to explore the application of B-LR to predictive modeling tasks in bioinformatics using informative biological prior probabilities. With informative prior probabilities, we conjecture that the performance of B-LR will improve.

Introduction

Biomedical data tend to have many variables and a scarcity of samples. Mining such high dimensional data with existing classifiers is challenging and the predictions are often inaccurate. Logistic regression (LR) is often applied in making predictions. However, it is difficult to include prior biological knowledge into the analysis when using LR. Almost all biomedical domains have associated domain knowledge. It would be helpful to be able to include such additional knowledge when building predictive models. For example, if a predictor variable is already known as a biomarker for a disease, it will be prudent to use this information when trying to come up with a model for classification and prediction for that disease. Prior knowledge can be incorporated into Bayesian Logistic Regression (B-LR) and the method is computationally efficient. B-LR has been applied successfully in text categorization [1], in integrating early physiological responses to predict later illness severity in preterm infants[2], and in early prediction of the response of breast tumors to neoadjuvant chemotherapy [3]. But in both [2] and [3], the number of predictor variables is small. We want to study the performance of B-LR on classifying high dimensional data and compare its performance to other existing classifiers. This paper uses a B-LR implementation that is readily available in the WEKA data mining environment[4]. Our goal is to understand the extent to which B-LR performs on par with other classifiers in WEKA according to the following performance measures – accuracy, balanced accuracy (i.e., average of sensitivity and specificity), and the area under the ROC curve (AUC).

Background

Linear logistic regression is a probabilistic classification model used for predicting a target variable depending on one or more predictor variables. It can give accurate predictions, but it often does not handle high dimensional data well. One way to overcome the shortcomings of LR is to apply a Bayesian approach with a prior probability distribution over predictor variables. In Bayesian analyses, the three steps involved are (1) specifying prior probabilities for the parameters, (2) determining the marginal likelihood of the data, (3) and using Bayes theorem to determine the posterior distribution of the parameters. B-LR captures the nonlinear relationships between the predictor variables and the outcome variable using Bayesian modeling. In B-LR, the equation for calculating the posterior probability of a sample belonging to a specific class is generated by the traditional logistic function:

$$P(Class|a_1, a_2, a_3, \dots, a_n) = \frac{1}{(1 + \exp\,(b + w_0 * c + \sum_{i=1}^{n} w_i * f(a_i)))} \quad (1)$$

Where, $'a_i'$ denotes the predictor variables, 'c' is the prior log odds ratio $\left(c = log\ \frac{P(\text{class}=0)}{P(\text{class}=1)}\right)$, the bias '$b$' and weights w_0 and w_i are learned from the training data, and the i^{th} attribute a_i is used to calculate the feature $f(a_i)$, using $f(a_i) = \log\left(\frac{P(a_i \mid \text{class}=0)}{P(a_i \mid \text{class}=1)}\right)$ (for binary class outcome variables). In the Bayesian approach to logistic regression, a univariate Gaussian prior with a mean '0' and a variance of 'σ_i' over the weights is commonly used. By

using a mean of '0', we assert our prior belief that the weights are close to zero. The values of σ_i are positive, with small values indicating our confidence in the values of the weights and larger values indicating the lack there of. Though this Gaussian prior favors weights with values close to zero, it does not favor the values exactly being zero. Maximum a posteriori (MAP) estimate of these weight values is similar to ridge regression for the logistic model.

The B-LR implementation in WEKA is based on [1] and has Gaussian parameter priors and Laplace parameter priors as the two options. Domain knowledge related to the datasets can be incorporated by specifying a prior, thereby defining a distribution over the values of the weights. Since the WEKA implementation of B-LR has Gaussian and Laplace priors as the two options available, we used only these non-informative priors in our analysis.

Experimental Method

Twelve datasets with binary class variables were chosen. Eleven are publicly available and one is a private dataset collected in the LungSPORE project[5]. The LungSPORE dataset contains as yet unpublished data that was collected to validate the results of an earlier study [5]. This study identified a panel of ten serum biomarkers that distinguished lung cancer from controls and have the potential to aid in the early detection of lung cancer and more accurate interpretation of indeterminate pulmonary nodules detected by CT screening.

Table 1. Details of the 12 datasets that were analyzed.
G/P indicates if the data is Genomic or Proteomic. P/D shows whether the data is Prognostic (P) or Diagnostic (D). The number of variables (Original) gives the total variables in the original dataset. The number of variables (PAIFE) gives the total number of variables after processing the dataset through our irrelevant feature elimination algorithm 'PAIFE'. The Sample (Class1, Class2) gives the total number of samples and class distribution, and 'Reference', the relevant reference to the dataset.

ID	G/P	P/D	Number of variables (Original)	Number of variables (PAIFE)	Sample(Class1,Class2)	Outcome variable	Reference
1	G	D	6584	1972	61(40,21)	Colon Cancer	Alon et al [6]

For high dimensional biomedical data, the presence of uninformative variables in the dataset introduces noise and adversely affects the performance of classifiers. As a preprocessing step, we used our in-house developed algorithm called 'Partitioning based adaptive irrelevant feature eliminator' (PAIFE) to remove presumptive non-informative features from the datasets[16]. PAIFE evaluates predictor variable – outcome variable relationships over not only a whole dataset, but also the partitioned subsets and is effective in identifying variables whose relevance to the outcome are conditional on certain other variables. In experiments with synthetic datasets, PAIFE had outperformed other state-of-the-art feature selection methods in retaining relevant features and eliminating irrelevant ones [16]. PAIFE successfully removed irrelevant features when tested on proteomic and genomic datasets and the models developed from the PAIFE processed datasets performed either better or on par with the models built without any processing.

The PAIFE processed datasets were then normalized using the unsupervised attribute filter 'normalize' in WEKA's preprocessing step. The following methods were applied with 10-fold cross validation on each of these PAIFE processed, normalized datasets: B-LR with both Gaussian and Laplace priors, B-LR with Gaussian priors and cross-validation-based hyperparameter selection [1], C4.5 (J48 in WEKA) [17], naïve Bayes [18], simple logistic regression [19, 20], ridge logistic regression [21], CART (SimpleCart in WEKA) [22], Random Forest [23], and SVM (SMO in WEKA[24]), as implemented in WEKA 3.6.10 [4]. Simple logistic regression (LR_{simple}) in WEKA is the linear logistic regression and ridge logistic regression (LR_{ridge}) is the logistic regression model with a ridge estimator. For all the classifiers, except B-LR with Gaussian priors and hyperparameter selection based on cross validation (CV), default parameter values in WEKA were used. That classifier was chosen by selecting the 'CV based hyperparameter' option in WEKA's B-LR classifier.

The statistical significance of the results was analyzed by paired two-tailed t-test and by non-parametric Wilcoxon paired-samples signed ranks test. We used the alpha value of 0.05 for significance testing.

Results

In our performance analysis, we compared the accuracy, balanced accuracy (BACC) and percentage AUC values of each classifier.

Table 2: Comparison of the accuracy (percentage) of the classifiers from 10-fold cross validation.

In tables 2, 3, 4, 5, and 6, we use B-LR_{GP1} to indicate B-LR with Gaussian priors, B-LR_{GP2} to indicate B-LR with Gaussian priors with cross-validation based hyperparameter selection, B-LR_{LP} for B-LR with Laplace priors, NB for Naïve Bayes, RF for Random Forest, 'Avg' for 'Average', 's.d.' for 'standard deviation'.

Table 2 shows the accuracy of all the classifiers on the different datasets. The bold value on each row indicates the classifier with the highest accuracy for that dataset.

Table 3 gives the balanced accuracy for the different classifiers with the bold numbers indicating the classifier with the maximum BACC value for a specific dataset. Table 4 shows the percentage of AUC values for each of the classifiers for all the datasets.

We evaluated the statistical significance of these performance measures using the paired two-tailed t-test and the non-parametric Wilcoxon signed ranks test. Tables 5 and 6 show the results. The captions of the tables explain the contents of their cells.

Table 5: Comparison of the classifiers using a paired two-tailed t-test.
The numbers shown are p-values; the values below 0.05 are shown in bold. The value in a parenthesis is the mean performance of B-LR minus the mean performance of the listed classifier, expressed as a percentage. The values underlined are those in which the p-value is less than 0.05 and B-LR performed better.

B-LR with Gaussian priors versus each of the following:	Accuracy	BACC	AUC
B-LR_{GP2}	0.18 (1.35)	0.73(0.31)	0.14(2.37)
B-LR_{LP}	**0.01**(4.39)	0.10(3.06)	**0.01**(7.42)

Discussion

From table 2 of the results, we can see that B-LR with Gaussian prior had the highest accuracy for three of the datasets and an average accuracy of 91.60%. Though SVM has outperformed B-LR with Gaussian prior with an average accuracy of 92.25%, the difference between the two values is very small (0.65%) and the standard deviation is 8.61 and 8.70, for B-LR and SVM respectively. B-LR with Gaussian prior has the maximum BACC value for three of the datasets and an average of 91.95%. SVM has the highest average BACC value of 92.13% leading B-LR with Gaussian prior by 0.18% (Table 3).

It is interesting to observe from table 4 that LR (with ridge estimator) has the highest AUC value of 92.18% when its accuracy and BACC measure were about 2% and 3% behind those of B-LR with Gaussian prior. In comparing the performance using paired two-tailed t-test and the non-parametric Wilcoxon signed ranks test, on accuracy, B-LR with Gaussian priors (B-LR_{GP1}) performed statistically significantly better ($p \leq 0.02$) than B-LR with Laplace priors, J48, Naïve Bayes, CART, and Random Forests. Only SVM had a higher accuracy, which was higher by 0.65% ($p = 0.06$). On BACC, B-LR_{GP1} performed statistically significantly ($p \leq 0.04$) better than J48, Naïve Bayes, LR_{simple}, CART, and Random Forest. No method had a statistically significantly better performance than B-LR_{GP1}, according to the BACC measure. On AUC, B-LR_{GP1} performed statistically significantly better ($p \leq 0.04$) than B-LR with Laplace prior, J48, and CART. LR_{ridge} and SVM had higher AUCs than B-LR_{GP1}, with LR_{ridge} being higher by 4.09% ($p = 0.04$) and SVM being higher by 1.29% ($p = 0.02$).

B-LR_{GP1} was also among the fastest methods, with an average time of 0.13 sec to build the model compared to LR_{ridge}'s average time of 13.45 sec.

In this study, we limited ourselves by using a single type of feature selection method, PAIFE. It would be important to learn the impact of the choice of feature selection method. In the future, we will examine other state-of-the-art feature selection methods and compare its performance to PAIFE. We would also like to observe the results without feature selection. Genkin et al. [1], observed that lasso logistic regression was effective on high dimensional data

analysis problems, it would therefore be interesting to observe the performance of lasso logistic regression on such higher-dimensional and noisier data.

Conclusion

The results from this study provide support that B-LR with a Gaussian prior performs well compared to a set of classifiers that include those often applied in bioinformatics. It provides researchers with an additional classifier from which they can choose when analyzing high dimensional data.

With these promising preliminary results, the next step will be to use biological domain knowledge to develop informative priors to use in B-LR, and then repeat the evaluation of its predictive performance. In this study, we analyzed only 12 datasets with binary class variables. We plan to extend our analysis to more datasets and datasets with multinomial class variables. Our future analysis will also evaluate the performance of B-LR when changing the parameter options in WEKA's B-LR classifier. For example, we used the default value of 100 for the number of iterations. We plan to have our own implementation of B-LR with options to choose the type of informative priors depending on the application domain.

Abstract

Digital desk technology has a still mainly unexplored potential to support the everyday work of collaborating clinicians. This paper presents ER Desk – a digital desk that was designed to specifically support a team of healthcare professionals working in an emergency room setting. The underlying design requirements were elicited in a comprehensive distributed cognition study of paper-based practices in an emergency room of a middle-sized Swedish hospital. We present the user interface and visualization requirements for digital desks for small clinical emergency room teams. Moreover, we discuss key design issues more generally with a focus on supporting team awareness, cognition, and collaborative routines of healthcare personnel working in clinical environments such as emergency rooms and intensive care units.

Introduction

Healthcare settings are highly collaborative work environments where the combined efforts of different professional groups are required to bring efficient and safe care. However, this basic requirement is not necessarily recognized in the design of the modern electronic patient-record systems (EMRs). It is currently common to employ desktop computers (EMR workstations) and replace paper forms with digital media when attempting to make the clinical work practices more rational and effective. Researchers have criticized this approach to computerization as it may impose unnatural and inefficient ways of working on the clinicians. This may, in fact add to the workload of the healthcare professionals rather than reduce it.[1,2,3] EMR systems have been deployed at all hospitals in Sweden. As a result, the clinical documentation processes have changed from a flexible and nomadic paper-based practice to a stationary and individualized process. One problem when substituting paper forms for digital media is that it deprives clinicians from informal information sharing possibilities that could facilitate the workflow and aid them in their situational awareness. Another disadvantage of the workstations is that they use small screens, which make them unsuitable for clinical real-time, face-to-face collaborations. Overall, the screens and interaction devices of such systems are clearly designed to be used by one person at a time.

An overview of the patients under treatment, the triage order, and the means to flexibly divide labor and share information are important qualities for healthcare teams at hospitals worldwide. However, adequate user interfaces for co-located care coordination and planning actions are still missing. Even in computerized healthcare settings is important team-oriented information still scribbled on large whiteboards or represented by stacking paper forms in special ways to visualize important care actions and prioritizations. We believe that using carefully designed interactive surfaces, such as digital desks with multi-touch functionality, is a promising approach to address the above-discussed issues. Such digital desks have primarily been developed in research environments[4] but are now starting to emerge on the commercial market.[5] However, there has been little work presented on the topic by researchers working in healthcare-related domains. Most efforts have been on medical imaging, where both augmented environment approaches[6] and multi-touch solutions have been presented[7].

The aim of this study was to examine how workflow processes uncovered in ethnographic workplace studies can be transformed into representations and systems functionality in a digital healthcare context. We present the ER Desk – a digital desk that was designed specifically to support a small team of clinicians working tightly in an emergency room setting. The foundation for the design was established during a comprehensive workplace study at an emergency room in a middle-sized hospital in Sweden during two periods in 2003 and 2007 respectively. The studies were made from the perspective of distributed cognition[8] – a viewpoint that acknowledges that cognitive processes such as memory, knowledge, and attention are distributed across people and artifacts rather than contained within a single individual. The paper is arranged as follows: first, we provide a brief introduction to the perspective of distributed cognition. Second, the paper offers an in-depth analysis how clinicians worked in the emergency room before a modern EMR system was installed with an analysis of their paper-based collaborative practices from the

perspective of distributed cognition. Third, we present the digital desk and its design components in relation to the analysis. Lastly, we discuss issues that are of importance for interaction designers that wish to develop interfaces for collaborative clinicians. In particular, we discuss matters related to cognition and collaboration in these settings.

Background

Distributed cognition and external tools

Workplace researchers have studied how professionals manage and share large amounts of information and knowledge in the workplace.[9-11] This research emphasizes the role of immediate here-and-now experiences and flexible user interaction techniques. For example, distributing paper forms on a desk to create a large display to facilitate a general overview of the patients under treatment is a common practice even in computerized wards. Having natural meeting places where patients can be discussed and actions coordinated improves learning, creates a general awareness of work-to-do, and simplifies the social distribution of work among the team members.[12,13] Distributed cognition emphasizes the social aspects of cognition and, particularly, how people arrange their physical environments to facilitate communication and to offload cognitively demanding tasks. According to Norman, so-called *cognitive artifacts*[14] – such as physical arrangements and visualizations – are particularly supportive since they aid memory and direct attention to the important tasks. This distributed cognition perspective can be used to generate design requirements to guide digital desk technology for healthcare teams.

Workplace study: Requirements on the digital desks

Our previous studies of teamwork in the emergency room setting have resulted in a set of high-level and low-level requirements for digital desks. Moreover, we have developed basic functional prototypes of digital desks for healthcare teams[16, 17]. The following is a brief synopsis of the clinical collaborative routines at a tabletop when the clinic was entirely paper-based.

Figure 1. The surgical team desk when the emergency department was paper-based in 2003.

Situational overview

The main team coordination artefact was an ordinary desk, centrally placed in the ER, with stacked patient folders (see Figure 1). It was used to visualize the *current state of the clinic and the workflow*. The arrangement of patient folders on this desk portrayed an *overview* of all cases being treated by members of the surgical team. The large display of folders (about 100 by 100 cm) facilitated an *on-the-fly visual evaluation* of the amount of work to be done. From a cognitive perspective, representations such as this arrangement function as an external memory and allow clinicians the use of less demanding, low-level perceptual routines (i.e., seeing the folders on the table) rather than high-level cognitive processes (i.e., keeping a list of cases in working memory) to assess a situation.

Collective clinical urgency ranking

The patient folders were arranged in two rows on the desk to signify the triage order and the work process (again, see Figure 1). Patients that had not been seen by the physician were placed in a row on the right side of the desk. This row portrayed the triage; that is, the prioritization of patients made by the head nurse. On the left side were folders of patients that were at the radiology department or awaiting test results. Much effort was devoted to *keeping the arrangement of folders and forms on the desk updated*. For example, clinicians moved the folders around on the desk to indicate patients' rank and position in the workflow, and they placed special plastic tags on the folders to designate where patients were treated (e.g., at the radiology department). This constant *cognitive activity* created a natural and *shared awareness* of patients with regard to urgency and an ordering of the activities of the team.

Signalling turn-taking

Signalling a clear handover of a task was important. Our study found that the specific placement of a folder on a desk could, for example, signify that the physicians asked the nurse to take a biomedical test. This simple and visible strategy for signalling and turn-taking was highly effective, because it reduced the need for verbal communication, and it also functioned as a persistent external memory of work-to-do.

Cognitive focusing by document order

In addition to the shared affordances, nurses arranged the paper forms within individual patient folders to offload cognitive tasks for the physicians. For example, newly-arrived laboratory results were placed in a folder in such a way that they were easily seen by the doctors, whereas unimportant information and forms were placed further back in the pile. These routines reduced the need for physicians to browse through the documents in search of necessary facts. From the perspective of distributed cognition, this collaborative technique can be seen as distributed cognitive processing and collaborative filtering of information[9] – an approach that changes the nature of subsequent tasks.

Digital desk technology

Wellner[4] proposed the digital desk concept in the early nineties. Basically, digital desks have a large area that can show computer-generated imagery, and they also permit tactile interaction, for example to annotate objects and move them around spatially to create order.[18, 19, 20] Some desk implementations recognize objects that are placed on the tabletop[21] and may also provide tactile feedback when an object is moved.[22] Other, more advanced desk-based interaction techniques are digital clay and sand that provide feedback to the user in real-time[23]. Several desk designs have been presented for various purposes such as education in the school setting,[24] landscape architecture,[23] and music creation[25]. Particularly interesting for this project are advances in multi-touch functionality that allow several individuals to work on the same digital desk simultaneously.[30-32] The devices and the software tools for developing multi-touch collaborative surfaces for digital desks are currently emerging on the market as off-the-shelf products. However, even though research in related domains such as pervasive healthcare and clinical visualization is abundant,[26-29] research on using digital desk technology in healthcare settings is scarce.

Method

Ethnographic research methods were used for a month-long period of qualitative data collection at an emergency room in a medium-sized Swedish hospital[16] from the perspective of distributed cognition.[8] The collected data were analyzed to create a requirements specification for the design of a digital desk graphical user interface (GUI).

Apparatus

A digital desk prototype was constructed using a 52 inch HDMI full-HD plasma screen with a 1920x1080 resolution measuring about 25x45 cm. The multi-touch sensor was a 52 inch IR-touch frame from IRTOUCH Systems. This frame was placed on top of a plate of glass and then placed on the plasma screen. A standard PC with a 3.1 GHZ processor and 4 GB RAM ran the tracking and visualisation software that was written in Delphi (tracking stokes) and Adobe Flex (visualisation). The PC had a wireless physical keyboard that became the main text input device.

Results

The resulting GUI was named ER Desk for ease of reference. The overall design was implemented on a large, multi-touch digital desk and was focused on supporting collaborating teams working in an emergency room setting. The design can be conceptualized as a shared workspace for physicians, nurses and nurse's aids. The overall goal was to allow the patient records – particularly the temporary clinical information and documents about the patients under treatment in the ward – to be visualised and accessed directly as virtual folders on a digital work surface to provide functional mapping from the paper-based system to the digital.

Overall design

The design principle was to exploit the supportive and flexible components of the practices previously recorded in the workplace studies. The interaction design basically followed the structure of how paper files were employed in the emergency room. Simple drag-and-move actions are used to create order and organize the work area. The urgency ranking approach and layout was an important feature of the paper-based clinic that supported overview of tasks and aided the workflow. To retain parts of this work method, we implemented a *patient strip* based on the concept of flight strips used by air traffic controllers[33]. Each patient is represented by one patient strip (see Figure 2). The strip can be configured to show key patient information, such as the patient identification number, the name of the patient, allergies, and sex of the patient. The information displayed on the strip can, unlike the paper-based strips used in air traffic control, be updated with new information continuously. For example, when the patient has been assigned to the clinic and a nurse has checked the patient, the strip can be updated to contain additional data such as the reason for the visit, blood pressure, heart rate, temperature, allergies, and medications. The central idea behind using strips was to allow clinicians to fairly freely create *their own* spatial representation of the work situation and the workflow using simplified representations of the electronic health care records. Hence, the patient strips can be stacked and arranged on the desk according to the clinical situation. For example the head nurse may convey triage order to the team, highlight prioritized patients, and demonstrate turn-taking of group tasks to facilitate the workflow. As an example, Figure 3 shows patient strips arranged in two rows to designate the workflow analogously to the paper stacks seen in Figure 1. When a patient strip is moved to the central area of the desk it opens to show the basic and shared nursing and physician documentation needed to treat this patient. The patient strip may contain physician orders, referrals, laboratory results, prescriptions, and similar information. These documents are in the current design accessed using tabs within the opened main view.

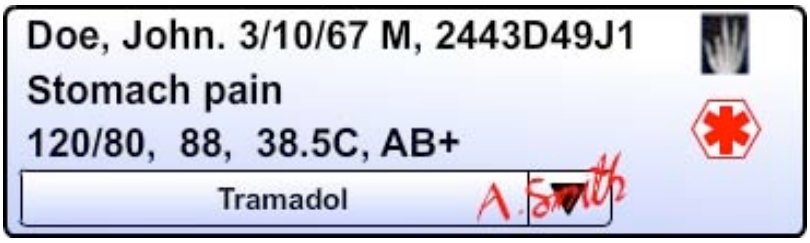

Figure 2. The Patient Strip. The strip holds a canonical set of medical information needed for the clinician to evalutate a situation, look for more information and take appropriate action. Moreover, the strip also says where the patient is currently situated within the hospital (the x-ray icon).

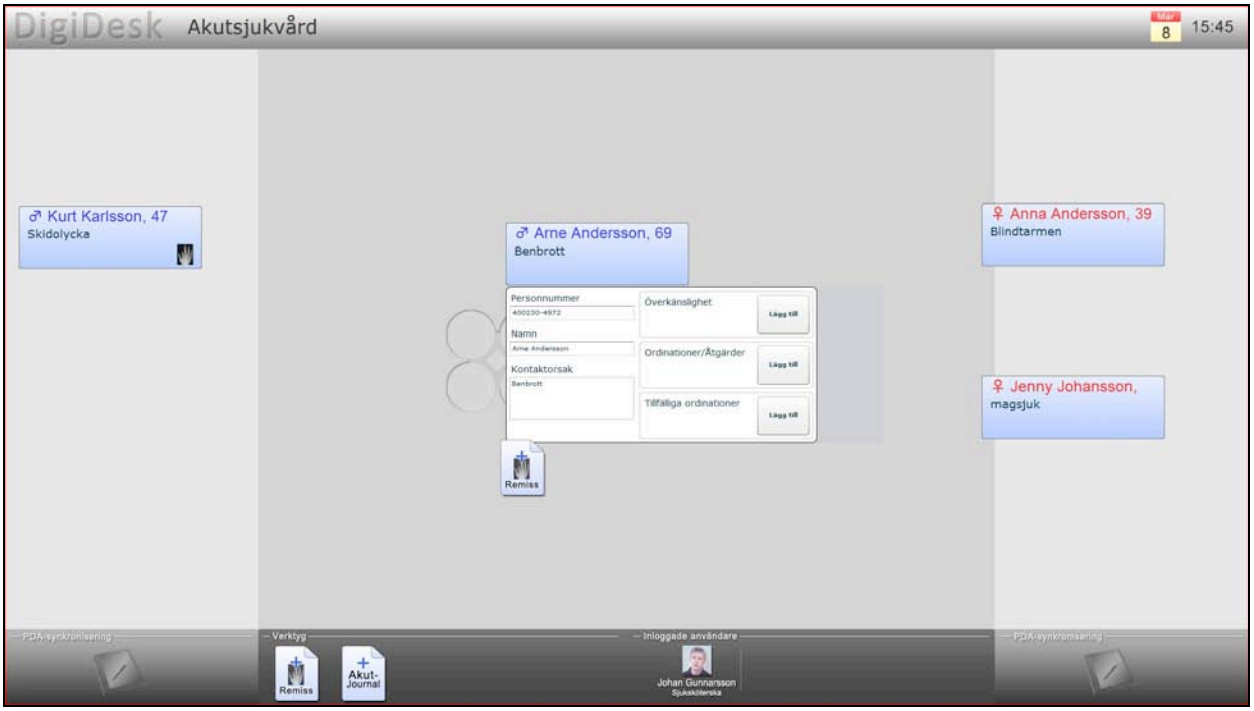

Figure 3. The ER Desk with patient strips. The icons in the dock are used to create new documents, such as a referral by dropping the icon on the activated patient strip. Moreover, the dock shows the active clinicians that are near the desk. Signing a referral or a biomedical test that has been taken is done by dragging and dropping the the personal icon on top of a data set or a document.

Situational overview and collective clinical urgency ranking

By utilizing a large (52") HD screen, a good situational overview of the patients can be obtained by both nurses and physicians based on the *spatial arrangement* of the patient strips. The two columns of digital patient strips at each side of the desk can be seen at a glance by the clinician to evaluate the amount of work to do for the team. For example, the patient strips can be placed in a sequence on the desk to convey the triage order. Each minimized patient strip also shows the most important information in this situation such as the basic biomedical measurements and important warnings (i.e., drug allergies).

Much work in healthcare is data driven, that is, nurses and doctors act on newly arrived information. The clinical workflow can thus be disrupted if new data does not arrive in a timely manner or is not intelligibly visualised to the responsible personnel. The patient strips should therefore be continuously updated and signal when new data, such as a lab result, has been received. In the current design, appearance of new data is highlighted on the patient trip as a flashing icon. In the current design, appearance of new data is highlighted on the patient trip as a flashing icon. Updates can also be tied to specific icons, such as using a flashing radiology icon for new X-ray images and the related diagnoses from the radiologist. A workspace is located at the center of the desk. Strips can be moved from the sides to the center, where they are opened, showing more information. This design maintains the sides for overview but allows the user to seek and display more detailed information for each patient. If one patient must be discussed by the clinical team, the desk can display this patient folder solely along with its main content similarly to opening and displaying the pages of a paper journal. This functionality allows clinicians to create meaning and discuss patient-related issues standing face-to-face or side-by-side.

Turn-taking and user defined cues

The prior workplace study revealed that the processes by which the clinical team hands over tasks and information between team members are intricate. This was often signalled by the spatial placement of the patient folder on the desk. For example, a physician could place a patient folder at a specific place on the desk to signify to the nurse that this patient needs an exam or that the patient has to be sent to the radiology department. This functionality was

mapped to the digital context by *allowing the operators to define and create their own cues* and customize the user interface to their own work process. The approach used in the present design to retain sufficient flexibility to allow such intricate handover processes is to use an open design. This means that the digital patient strips can be placed wherever on the desk, be adjusted or skewed slightly to the right or left to highlight a strip by letting it stick out from the rest. The meaning of these functions are not imposed by the designer but rather left to the clinical team to allow processes and markers to be defined socially in the team at "run-time".

Cognitive focusing by document order

In the paper-based system, each patient folder contained physician orders, referrals, laboratory results, and prescriptions. In the workplace study, we saw that these document were arranged within the folder by nurses so that a physician could find and process the most relevant and pressing information without effort. Thus, in a digital context, collaborative ordering of information within an electronic healthcare record must be allowed. This can be achieved by using tabs within an open electronic patient strip, such that each tab corresponds to individual documents. The team could rearrange these tabs so that they can create order and highlight the most relevant information in each situation.

Discussion

This study set out to examine how workflow processes uncovered in ethnographic workplace studies can be transformed into representations and systems functionality in a digital healthcare context. A large-surface digital desk was selected as the technical medium rather than a traditional computer workstation to facilitate overview, shared situational awareness, and to retain the workflow from the paper-based context. In particular, the current work outlines the design used to capture the situational overview, collective clinical urgency ranking, turn-taking, and cognitive focusing processes defined by the workplace study. Rather than using the PC desktop metaphor as a way to visualize workflow (e.g., Windows or MacOS), the ER Desk design relied on the workflow (i.e., cognitive functions) as revealed by the previous ethnographic study of one specific ER. This metaphor was augmented using the concept of patient strips, inspired by air traffic control. The design process highlighted two major design problems when developing a multi-touch desk for a healthcare team; how one should appropriately represent *a set of patients* on the one hand and *the individual patient* on the other. The general principle outlined by Shneiderman and colleagues[34] provides some guidance for this problem. They suggest that it is important to have overview first, and then have so-called "zoom and filter functionality" to obtain details-on-demand.[34]

Visualising patient sets

The visualization of patient sets can be said to represent a *clinic-overview* where all patients under treatment are visualised. The overview was, in our case, provided by a set of patient strips. The advantage of using strips is that it readily maps onto the work plan in a sequential process. This view and layout is common at hospitals today. From a distributed cognition perspective it functions as an external memory and could – given a social contract on the meaning of the spatial layout – provide cues on what to do next.[15] Having an open design allows clinicians to create meaning from functions in their social context. For example, clinicians may choose to convey important informal messages just by shifting the alignment of strips slightly because this cue yet has no a priori ascribed meaning. However, an open design that relies on a social contract could – particularly when there are many clinicians working at the clinic – be difficult to use for clinicians that work part-time. Novice users of the system may find it difficult to remember parts of the turn-taking system and the meaning of the spatial ordering of strips.

There are other approaches to metaphor and representation in the emergency room case, and choosing one or another would affect the in situ cognition and collaboration. For example, a strictly spatial view could be used as the underlying interaction metaphor, such as showing a map over the clinic and its beds with patient records laid out as the actual patients. Such representations cannot easily convey triage order but readily maps the location of the patient with the clinic. Nevertheless, the choice of underlying metaphor for the GUI representation should be anchored in ethnographic studies of current practices, which also involves the actual users early in the design process.

Visualizing individual patient data

Visualizing individual patient data is in the present design implemented as a basic *diagnosis view* where the vital signs, referrals, and lab results are shown. There has been some research on the visualization of patient data,[27, 28]

though these representations seem to take a limited view on patient visualisation. In the case of a digital desk design the question is more complex. The design problem, from a distributed cognition standpoint, is to find a way to visualise "*the big picture*" at the same time as providing detailed information. The physician needs to have *cognitive cues* and the exact information to take decisions, and *low-level cues* to support where to look. Also, the creation of cues may be distributed across members of the clinical team, which may support search, cognition and attention implicitly. Hence, it is important that designers carefully acknowledge these intricate cognitive processes and provide (open) designs that support distributed cognition.

Conclusion and Future Work

This paper presented a digital desk design developed to support a team of collaborating clinicians working in an emergency room setting. Specifically, the interaction design focussed on supporting face-to-face collaborative actions as well as decreasing the cognitive load on the clinicians. Future work includes studies on how to visualise single patients and sets of biomedical data appropriately, as well as evaluation studies of the design concepts outlined in the current paper. Further research is also needed on how to translate locally discovered workflow metaphors in a digital domain from one clinic to another, and how open design concepts are used and developed through shared, social practices in the workplace.

Learning to Identify Treatment Relations in Clinical Text

Cosmin A. Bejan, PhD[1] and Joshua C. Denny, MD, MS[1,2]

[1]Department of Biomedical Informatics, Vanderbilt University, Nashville, TN;
[2]Department of Medicine, Vanderbilt University, Nashville, TN

Abstract

In clinical notes, physicians commonly describe reasons why certain treatments are given. However, this information is not typically available in a computable form. We describe a supervised learning system that is able to predict whether or not a treatment relation exists between any two medical concepts mentioned in clinical notes. To train our prediction model, we manually annotated 958 treatment relations in sentences selected from 6,864 discharge summaries. The features used to indicate the existence of a treatment relation between two medical concepts consisted of lexical and semantic information associated with the two concepts as well as information derived from the MEDication Indication (MEDI) resource and SemRep. The best F1-measure results of our supervised learning system (84.90) were significantly better than the F1-measure results achieved by SemRep (72.34).

Introduction

Discovering treatment relations from clinical text is a fundamental task in clinical information extraction and has various applications in medical research. For instance, the availability of treatment relations could enable a more comprehensive understanding of a patient's treatment course,[1,2] improve adverse reaction detection,[3] and assess healthcare quality.[4,5] However, such relations are not stored in a structured format in most electronic medical records (EMRs), but rather they are encoded in narrative patient reports. Therefore, natural language processing technologies need to be employed to facilitate the automatic extraction of treatment relations from clinical text.

A treatment relation is a relation holding between two medical concepts in which one of the concepts (e.g., a medication or procedure) is a treatment for the other concept (e.g., a disease). The treatment relation between the concepts highlighted in (1), for instance, is defined by a medication(*levofloxacin*) as a treatment administered for a disease(*pneumonia*). The relation in (2), holding between a procedure(*surgery*) and a disease(*lumbar stenosis*), represents another common category of treatment relation. On the other hand, the relations between the emphasized concepts in (3) and (4) do not constitute treatment relations. As observed in (3), in spite of a medication being prescribed for a specific medical problem, the treatment did not cure or improve the medical condition of the corresponding patient. Similarly in (4), although *lorazepam* can be indicated for *nausea*, the context in which these concepts are described invalidate the existence of a treatment relation. Due to this observation, the only treatment relations in (4) are between *morphine PCA* and *pain*, *IV lorazepam* and *anxiety*, and *IV reglan* and *nausea*. The remaining pair combinations of the concepts from this example constitute non-treatment relations.

(1) *She switched to* [***levofloxacin***] *for treatment of* [***pneumonia***] *as evidenced on CT.*

(2) *He had a previous* [***surgery***] *for* [***lumbar stenosis***].

(3) *She was treated with* [***morphine***]*, which did not control her* [***pain***].

(4) *She will be discharged with her morphine PCA for pain, scheduled* [***IV lorazepam***] *for anxiety, and scheduled IV reglan for* [***nausea***].

Our approach for identifying treatment relations in clinical text is based on (a) the idea of exploring the contextual information in which medical concepts are described and (b) the idea of using predefined medication-indication pairs. For this purpose, we used MEDication Indication (MEDI),[6] a large database of medication-indication pairs. Another resource we employed in the feature extraction phase of our machine learning framework is SemRep,[7] which uses linguistic rules to identify treatment relations in text. For example, a rule of the form *X for treatment of Y* can be applied to find the treatment relation in (1).

The goal of our study was not only to build a system for accurately extracting treatment relations from clinical notes, but also to use this system for expanding MEDI with new medication-indication pairs.

Related Work

SemRep is a publicly available biomedical information extraction tool which was developed at the U.S. National Library of Medicine (http://semrep.nlm.nih.gov) and has been used by a number of investigators. Given a text document, this system analyzes each sentence from the document and identifies multiple types of semantic relations between the concepts described in the sentence. Examples of relations that SemRep is able to extract are DIAGNOSES, CAUSES, LOCATION_OF, ISA, TREATS, PREVENTS, etc. The system relies on MetaMap[8] to extract the Unified Medical Language System (UMLS) concepts from text and on linguistic and semantic rules specific to each relation. Its output for each sentence consists of a list of all the UMLS concepts mentioned in the sentence followed by the semantic relations that exist between these concepts. SemRep has been used in a wide range of applications in biomedical informatics including automatic summarization and literature based discovery.[9,10] While SemRep was primarily designed for processing documents from the biomedical research literature, only a few studies involving this system have been performed on clinical documents. In one of these studies, drug-disorder co-occurrences were computed from a large collection of clinical notes to improve the SemRep performance on extracting treatment relations from Medline citations.[11] Another study focused on how the semantic relations extracted by SemRep from Medline abstracts can guide the process of labeling concept associations from clinical text.[12]

One of the first machine learning systems developed to extract treatment relations from clinical text is described in Roberts et al.[13] In this work, the evaluation was performed on a small set of 77 oncology narratives, which was manually annotated with 7 categories of semantic relations. The feature set comprises various lexical, syntactic, and semantic features designed to capture different aspects of the relation arguments. Using a classification framework based on support vector machines (SVMs), the system achieved an average F1-measure of 72 over the 7 relation categories. An SVM-based framework was also developed by Uzuner et al.[14] to identify treatment relations defined for a more specific scope. To represent treatment relations, the authors of this study utilized sematic categories of concepts and the assertion values associated with these concepts. Examples of relation categories consist of present disease-treatment, possible disease-treatment, and possible symptom-treatment. Using a rich set of features, the SVM-based relation classifier recognized 84% and 72% of the relations annotated in two different corpora. Furthermore, due to its importance, the task of treatment relation extraction was part of the 2010 Informatics for Integrating Biology and the Bedside (i2b2)/Veteran's Affairs (VA) challenge.[15] Examples of treatment relations devised for this competition include relations in which the corresponding treatment (a) has cured or improved a medical problem, (b) has worsened a medical problem, (c) has caused a medical problem, (d) has been administered for a medical problem, and (e) has not been administered because of a medical problem. The concept pairs that occurred in the same sentence and did not fit this criteria were not assigned a relationship. The majority of the systems solving the 2010 i2b2/VA task on relation extraction relied on supervised machine learning approaches.[16–19]

In our preliminary studies,[20] we have implemented a simple algorithm using MEDI and have shown that it is a reliable method on assessing the validity of treatment relations identified in clinical notes. Like SemRep, MEDI is also publicly available (http://knowledgemap.mc.vanderbilt.edu/research/). It was developed by aggregating RxNorm, Side Effect Resource (SIDER) 2,[21] MedlinePlus, and Wikipedia and was designed to capture both on-label and off-label (e.g., absent in the Food and Drug Administration's approved drug labels) uses of medications. While RxNorm and SIDER 2 store the medication and indication information in a structured format, MedlinePlus and Wikipedia encode this information in narrative text. Therefore, further processing of the documents from MedlinePlus and Wikipedia was performed including the use of KnowledgeMap Concept Indexer[22,23] and custom-developed section rules to identify the text expressions describing indications and to map them into the UMLS database. The current version of MEDI contains 3,112 medications and 63,343 medication-indication pairs.

Method

We implemented a supervised learning framework that is able to predict whether or not two concepts co-occurring within the same sentence are in a treatment relation. To capture the relationship between the two concepts, we extracted various features based on the lexical information surrounding the concepts, on the semantic properties associated with the two concepts, and on the information derived from both MEDI and SemRep.

MEDI-based treatment relation extraction

A simple algorithm for treatment relation extraction is based on the assumption that any two concepts that co-occur within the same sentence and match a medication-indication pair in MEDI are likely to be in a treatment relation.

Table 1 The set of features for predicting whether two UMLS concepts are in a treatment relation.

Feature	Description
f_1:*semrep*	Boolean feature that is true whether SemRep indicates a treatment relation between the two concepts.
f_2:*medi*	Boolean feature that is true whether there is a match between the two concepts and a medication-indication pair in MEDI.
f_3:*semrep or medi*	Boolean feature that is true whether *f1* is true or f_2 is true.
f_4:*unigram*	The lowercased word unigrams surrounding the two concepts.
f_5:*bigram*	The lowercased word bigrams surrounding the two concepts.
f_6:*expression*	The lowercased word expression describing each of the two concepts.
f_7:*cui*	The concept unique identifiers (CUIs) of the two concepts.
f_8:*sem type*	The semantic types associated with the two concepts.

Despite the fact that this assumption does not take into account the context in which the two concepts are mentioned, our review of clinical documents before this study revealed that it holds true for the majority of the cases.

To increase the coverage of MEDI, we expanded the initial set of medication-indication pairs by using ontology relationships from the RxNorm database. For instance, because the medications in MEDI are mapped to generic ingredients,[6] the resource contains pairs involving RxCUI#1000082 (a*lcaftadine*), but it does not include pairs with medications containing alcaftadine ingredients such as RxCUI#1000083 (a*lcaftadine 2.5 MG/ML*) or brand medication names of alcaftadine as, e.g., RxCUI#1000086 (*lastacaft*). The relations we used to perform this expansion are *has_ingredient* and *tradename_of* from MRREL.

Features for predicting treatment relations

To learn a prediction model that is able to differentiate between pairs of UMLS concepts in treatment relations and the ones not belonging in such relations, we extracted the set of features described in Table 1. In this table, each feature was designed to capture a specific property associated with a pair of concepts. For instance, the lowercased word bigrams surrounding the emphasized concepts in (1) are "*switched to*", "*for treatment*", "*treatment of*", and "*as evidenced*". Also in (1), the semantic types extracted by MetaMap for *levofloxacin* are 'antibiotic' and 'organic chemical', and the semantic type for *pneumonia* is 'disease or syndrome'. As observed, since a concept can be associated with multiple semantic types in the UMLS Metathesaurus, the *sem type* feature can have multiple values for each concept. Of note, before the feature extraction phase, we assumed that the medical concepts were already identified in text and mapped to concepts in the UMLS Metathesaurus using SemRep.

In addition to the features listed in Table 1, we investigated the contribution of several other features including more word n-gram features and the version of f_4, f_5, and f_6 without lowercasing their corresponding textual expressions. We also extracted the concept preferred names and the semantic group(s) in which the semantic type(s) of each concept belongs to. None of these features were able to improve the overall performance of our prediction system.

Evaluation

To train our supervised learning system, we first constructed a dataset annotated with treatment and non-treatment relations. Based on this dataset, we then evaluated the performance results of our system and compared them against the results achieved by SemRep.

Dataset

For creating the dataset with annotated treatment relations, we randomly selected 6,864 discharge summaries from the Vanderbilt Synthetic Derivative, a de-identified version of the electronic medical record. In the data processing phase, we first split the content of each report into sentences using the OpenNLP sentence detector (http://opennlp.apache.org/) and removed the duplicate sentences. The output generated by this process consisted of 290,911 sentences. We then parsed these sentences with the current version of SemRep, v1.5, which identified 943,306 UMLS concepts (~3.2 concepts/sentence), and 3,386 treatment relations in 2,841 sentences. Next, we ran the MEDI algorithm over the same concepts extracted by SemRep in the previous step. Since SemRep is designed to identify treatment relations at sentence level, we constrained the algorithm based on MEDI to match any pair of concepts mentioned within the same sentence. As a result, 3,716 MEDI relations were obtained.

Table 2 Results for extracting treatment relations from text.

System	TP	FP	FN	TN	P	R	F
SemRep	625	145	333	9483	81.17	65.24	72.34
Our system	790	113	168	9515	87.49*	82.46*	84.90*

*p<0.001; statistically significant differences in performance between our system and SemRep.
F, F1-measure; FN, false negatives; FP, false positives; P, precision; R, recall, TN, true negatives, TP, true positives.

In the manual annotation phase, two reviewers examined 620 sentences in which the MEDI algorithm and SemRep identified at least one relation. We decided on this set of sentences to cover as many SemRep and MEDI relations as possible and, at the same time, to minimize the annotation effort. However, since all these sentences contain relations identified by both SemRep and the MEDI algorithm, one limitation of this selection is that the evaluation of the two systems may result in overestimating their corresponding recall values. Blinded from the results extracted by SemRep and the MEDI algorithm, the annotation process consisted of manually linking pairs of concepts that represent treatment relations inside every sentence. Once a sentence was annotated, the remaining combinations of concept pairs in the sentence were automatically marked as non-treatment relations. During this process, the reviewers performed a double annotation on 25% of the data obtaining a percentage agreement of 97.9, with the Cohen's Kappa value of 0.86. In the manual annotated dataset, the disagreements were adjudicated by an experienced clinical expert. For annotation, the BRAT annotation tool[24] was employed resulting in 958 and 9,628 treatment and non-treatment relations, respectively.

Results

We evaluated our machine learning framework on the manual annotated dataset using a 5-fold cross validation scheme. For performing the classification of treatment and non-treatment relations, we employed LIBSVM (http://www.csie.ntu.edu.tw/~cjlin/libsvm/), an implementation of the SVM algorithm. In all experiments, we used the radial basis function as the kernel function of choice. Since our interest was in detecting the treatment relations as accurately as possible, we measured the performance results of our system in terms of precision, recall, and F1-measure.

In Table 2, we report the results obtained from comparing the manual annotated relations with the relations extracted by SemRep and our system. Our system results were obtained by aggregating the results over the test folds during cross validation. As observed, our system managed to achieve significantly higher results than the SemRep results. To measure the statistically significant differences in performance between the two systems, we employed a randomization test based on stratified shuffling.[25]

To get a better insight of the features extracted for identifying treatment relations, we performed several feature ablation studies. The findings of these studies are listed in Tables 3(a) and 3(b). The experiments in Table 3(a) show the contribution of each feature to the overall performance of our system. As indicated, the largest drop in performance is caused by the *sem type* feature. This behavior is expected since there is a clear pattern in the semantic types corresponding to most of the concepts participating in treatment relations. For instance, the medication-disease and medication-medication relation types represent strong indicators for treatment and non-treatment relations, respectively. However, to properly estimate the contribution of SemRep and the MEDI algorithm to the overall performance of our system, we also performed experiments using the All – {*semrep*, *semrep or medi*} and All – {*medi*, *semrep or medi*} feature configurations. This is because the *semrep or medi* feature is highly correlated with the *semrep* and *medi* features. For instance, if *medi* is true for a given concept pair, the *semrep or medi* feature is also true for the same concept pair. Using the All – {*semrep*, *semrep or medi*} configuration, our system achieved a recall of 78.39 and an F1-measure of 82.03. When All – {*medi*, *semrep or medi*} was employed, the recall and F1-measure values dropped to 73.49 and 79.82, respectively.

The experiments from Table 3(b) show how our system performed when only one feature from Table 1 was selected to differentiate between treatment and non-treatment relations. The best performing experiments in this table are the ones employing the results of the MEDI algorithm (i.e., *medi* and *semrep or medi*). The results of these experiments are also statistically significant from the results of the *semrep* experiment (p<0.001). Also interestingly, the machine learning framework using only the *sem type* feature was able to obtain better results than SemRep (74.08 vs. 72.34). Nevertheless, the difference in performance was not statistically significant. Of note, the machine learning framework using only the *semrep* feature was able to find the same separation of the relations as the SemRep

Table 3 Feature ablation studies for treatment relation extraction.

(a)

Features	P	R	F
All – *semrep*	85.12	82.99	84.04
All – *medi*	84.95	83.09	84.01
All – *semrep or medi*	87.88	81.00	84.30
All – *unigram*	86.75	82.05	84.33
All – *bigram*	86.74	81.94	84.27
All – *expression*	87.58	81.73	84.56
All – *sem type*	85.94	81.00	83.40
All – *cui*	87.00	81.00	83.89

(b)

Features	P	R	F
semrep	81.17	65.24	72.34
medi	80.48	76.62	78.50
semrep or medi	73.61	85.91	79.29
unigram	63.56	39.87	49.01
bigram	77.89	16.18	26.79
expression	74.27	39.77	51.80
sem type	68.78	80.27	74.08
cui	68.80	49.48	57.56

All, the entire set of features from Table 1; F, F1-measure; P, precision; R, recall.

system. As observed, the SemRep results in Table 2 are identical with the results of the *semrep* experiment in Table 3(b). Similarly, the MEDI algorithm achieved the same performance results as the results of the *medi* experiment.

Error Analysis

The cases when the MEDI algorithm was not able to find an exact match for a given concept represented some of the most frequent false negative examples of our system. For instance, the relation *sucralfate→heartburn* does not have a corresponding medication-symptom pair in MEDI despite the fact that related concepts such as *esophagitis*, *burn of esophagus*, and *esophageal reflux* are included in the list of indications for *sucralfate* in this resource. Likewise, the relation *unasyn→pneumonia* cannot be matched by the algorithm although a medication-indication pair between *unasyn* and a more general concept of *pneumonia*, *communicable diseases*, exists in MEDI. Furthermore, from the false positive examples we analyzed, many of them occurred in complex sentences in which the context is critical in determining the relationship between concepts. The emphasized concepts in (4), e.g., represent a false positive instance because they correspond to a medication-indication pair in MEDI.

Discussion

Our experiments indicate that a machine learning framework is a successful approach for capturing treatment relations in clinical text. By incorporating various sources of lexical and semantic information associated with relation concepts as well as information extracted from a knowledge base of medication-indication pairs, our system managed to improve the performance results over SemRep, a widely used rule-based system in information extraction applications. The major improvements in recall over SemRep due to the information derived from MEDI confirmed our assumption that a valid medication-indication pair expressed in a sentence corresponds to a treatment relation in the majority of cases. Furthermore, as observed from the results of our experiments, the most significant decrease in recall and F1-measure is achieved when discarding all MEDI related features (i.e., using the All – {*medi*, *semrep or medi*} feature configuration). Despite the fact that SemRep was not particularly implemented for the clinical domain, our experiments from Tables 2 and 3(b) showed that this system is able to extract treatment relations with high precision. This study also adds to the relatively few evaluations of SemRep on clinical text, demonstrating that it does work in this domain also.

It is worth mentioning that both the MEDI algorithm and SemRep are not able to identify all treatment relation types. For instance, since the first argument of the treatment relation in (1) is a procedure, the concept pair from this example will not have a corresponding match in MEDI. Similarly, in SemRep, the types of the relations extracted from text are constrained to match the types of their corresponding relations in the UMLS Semantic Network.[7,26,27] As illustrated in Figure 1, only 9% of relations are identified by the two algorithms from the total number of relations extracted over the entire collection of 6,864 discharge summaries. The top 3 most frequent types of these relations are listed in Table 4. In this table, each relation type is described using the UMLS semantic types associated with the relation arguments. Not surprisingly, the most frequent relation type identified by both algorithms is the one abbreviated as orch,phsu→sosy, which represents the generic type of medication *treats* disease. On the other hand, the next two most frequent SemRep relation types (i.e., topp→dsyn and topp→podg) have procedure as first argument and therefore, they were not found among the MEDI relation types. From the types identified by the MEDI algorithm in Table 4, clnd→sosy was not found in the relation types extracted by SemRep.

Figure 1 The connection between the relations identified by the MEDI algorithm and SemRep.

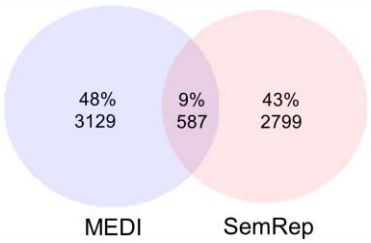

Table 4 Top 3 most frequent relation types identified by the MEDI algorithm and SemRep. The semantic types of the relation arguments are abbreviated as returned by MetaMap.

SemRep relation types	Freq.	MEDI relation types	Freq.
orch,phsu→sosy	425	orch,phsu→sosy	1582
topp→dsyn	324	orch,phsu→dsyn	616
topp→podg	264	clnd→sosy	270

clnd, clinical drug; dsyn, disease or syndrome; orch, organic chemical; phsu, pharmacologic substance; podg, patient or disabled group; sosy, sign or symptom; topp, therapeutic or preventive procedure.

In future research, we plan to improve our machine learning framework by implementing additional features that are able to better differentiate treatment relations from non-treatment relations. For instance, features using the structural and syntactic information derived from constituent and dependency trees could better capture the contextual properties between two medical concepts.[13,14,28] For this task, assertion classification[29] can also be investigated to better detect the relations whose corresponding treatment did not improve or cure a medical condition. Other technologies that may improve treatment relation extraction are statistical feature selection[30] and learning methods for imbalanced data.[31] Moreover, we intend to run our system over a large collection of clinical notes that could enable the discovery of new medication-indication pairs. Examples of pairs not in MEDI that our machine learning system was able to extract included valid relations such as *ethambutol→infection*, *lidocaine→stump pain*, *famvir→oral ulcers*, *levaquin→pyuria*, and *vesicare→bladder spasm*.

Conclusion

In this paper, we described a supervised learning system for identifying treatment relations in clinical notes. Our system successfully integrated various types of information which lead to achieving significantly better performance results than SemRep. One relevant source of information which had a major impact in boosting our system's recall is MEDI. As we empirically proved, MEDI is a broad and reliable resource on assessing the validity of treatment relations. We believe that future information extraction systems in the clinical domain should rely on a knowledge base of medication-indication pairs to accurately identify treatment relations in text. We plan to further improve this task and to assess its usability in various clinical applications.

An Exploration of the Potential Reach of Smartphones in Diabetes

Katherine S Blondon, MD, PhD[1], Paul L Hebert, PhD[1], James D Ralston, MD, MPH[1]
[1]University of Washington, Seattle, WA

Abstract

Although smartphones bear potential to improve diabetes self-management, the reach of smartphones in diabetic populations remains uncertain. Using survey data from the Pew Research Center, we compared smartphone use in individuals with and without diabetes, and determined factors associated with smartphone use among those with diabetes. Of the 2989 adults surveyed, 1360 were smartphone users, and 332 individuals had diabetes. Compared to individuals without diabetes, adults with diabetes were less likely to be smartphone users (relative risk of 0.43, 95% CI 0.31 to 0.54) even after adjusting for age, race, ethnicity and socioeconomic status (adjusted RR of 0.78, 95%CI 0.57-0.98). Among individuals with diabetes, high income, younger age and online health information seeking were associated with higher smartphone use. While smartphones can reach subgroups for diabetes care and prevention (racial/ethnic minorities, newly diagnosed individuals), studies are needed to understand this current difference in smartphone use.

Introduction

Smartphones have shown potential in improving diabetes self-management. The rapid adoption of smartphones[1] and the rising prevalence of diabetes[2] have led to the development of a large array of supportive applications aimed at improving diabetes self-management in daily tasks and choices: they help learn about diabetes and its management, track health parameters with graphs and data sharing options, and allow calendaring for daily tasks or annual screening procedures[3, 4]. Seven out of ten American adults track a health parameter such as weight, exercise or sleep[5], and one in five smartphone users having a health app on their device[6]. Although treatment goals are well established[7], less than one fifth of patients achieve HbA1c, blood pressure and LDL-cholesterol goals[8]. A meta-analysis of 22 trials assessing the effect of mobile phone interventions on glycemic control showed a reduction of HbA1c of 0.5% over a median of 6 months' follow-up duration[9]. A randomized controlled trial with a smartphone application that offers automated clinical coaching based on patient-reported data and that supports data-sharing with care providers, showed a 1.2% greater decrease in HbA1c with web- and mobile-based tools compared to usual care over a year (1.9% in web- and mobile-based group vs 0.7% in usual care group, $p<0.001$)[10]. Early studies suggest promise of effective support for diabetes self-management with smartphone applications.

The uptake of smartphone applications depends on consumer access to the devices, as well as on human-computer interaction issues including sufficient functionality and usability[11]. Although studies have characterized who has diabetes and smartphone users, we do not have a clear understanding of the socio-demographic characteristics associated with smartphone use among individuals with diabetes. The exponential growth in smartphone adoption has reached more than half of US adults, who are from all demographic groups[1, 12]. The diffusion of innovation theory[13] claims that age predicts the adoption of technologies, with the younger population adopting new technologies before the older population. Although higher income and higher education are strong predictors of all-age smartphone adoption, younger adults seem to be less affected by these variables. Asians and African Americans are more likely to be smartphone users than Caucasians, and African-Americans are also more likely to have health applications on their phone than other racial/ethnic groups (15% of African Americans vs 7% of whites and 11% of Latinos). This difference is particularly relevant, as these groups also have a higher prevalence of diabetes (11.8% of Hispanics, 12.6% of non-Hispanic Blacks compared to 8.3% of the U.S. population)[14, 15], with lower glycemic control in African Americans and Hispanics. Diabetes prevalence is also higher with increasing age (13.7% in the 45-64 year old group, and 26.9% in those over 65 years old)[15].

The aim of this study is to identify the reach of use smartphones among individuals with diabetes and to examine the socio-demographic profile of smartphone users with diabetes. Although many smartphone and tablet applications to support diabetes self-management are available, characteristics of smartphone users in the targeted population remain unclear. These characteristics are important, if developers desire to tailor mobile apps to the users' needs.

We hypothesized that compared to individuals without diabetes, individuals with diabetes will be less likely to use smartphones, due to older age and lower socioeconomic status (SES)[15]. We also hypothesized that individuals with diabetes would be more likely to use smartphones if they have a higher level of education, younger age, non-White

race and high income[16]. Finally, as many of the current diabetes application features involve data tracking and interpretation[3, 4], we hypothesized that smartphone use among diabetics would be associated with higher self-monitoring. Understanding who uses and does not use smartphones among patients with diabetes can inform future diffusion and design of diabetes applications.

Methods

Population

This cross-sectional study uses a survey dataset of the Pew Research Center collected between August 7 and September 6, 2012. This data was collected initially to describe the use of mobile technology for health[17]. Researchers conducted a nationwide survey in the U.S. using phone interviews in English and Spanish of 3,014 adults >18 years old (1,808 landline and 1,206 mobile users). Participant selection was by random digit dial of both landline and cellphone numbers. For landline sample, the interviewers followed a systematic respondent selection technique that closely mirrors the population in terms of age and gender when combined with cellphone sample. Both samples were oversampled for Black and Hispanic respondents. Response rates were 11.5% for landlines and 6.6% for cell phones (total of 58,848 landlines and 32,129 cell phones dialed). The survey weights supplied with the survey[17] were used to generate population level estimates. The margin of sampling error was ±2.4 percentage points for the complete set of weighted data. This survey was conducted by Princeton Survey Research Associates International and sponsored by the Pew Research Center's Internet & American Life Project and the California HealthCare Foundation. This current study was conducted with the permission of the Pew Research Center's Internet & American Life project.

Survey

This phone survey was created to study how cell phones, particularly smartphones, are used to look for health information. It included questions about self-reported health conditions (overall health and common chronic diseases), tracking behaviors (in particular of weight, diet, exercise, and blood pressure), use of social networks, and searching for online health information about specific diseases or treatments, heath insurance, or more general food and drug safety information. The complete interview (26 questions) can be found online[18].

Analysis

The primary analysis (Table 3) compared the use of smartphones between diabetic and non-diabetic participants using unadjusted and adjusted weighted logistic regression models. Smartphone users were defined as any user of a smartphone, including those who had both a landline and a smartphone. Non-smartphone users were all other participants, and included feature phone (cell phone that is not a smartphone) users and landline-only users. The covariates in the logistic regression models were defined a priori, with an age-adjusted model and the full model (age, measures of socio-economic status, race, ethnicity). Age was hypothesized to be the main confounder of smartphone use and diabetes. The other demographic confounders are based on results from market studies of smartphone use. In these models, age, race, income and education were categorical variables, as presented in tables 1 and 2.

The secondary analysis (Table 4) used a multivariate logistic regression model among diabetics to estimate predictors of smartphone use. All variables of interest were chosen a priori by the investigators and entered together in the model: age (categorical), race and ethnicity, education and income (all binary). For this secondary analysis, we used a binary variable combining race and ethnicity, as well as binary variables for education and income to avoid having too few events per variable. Education was defined using a threshold of high school completion. The cutoff for income level of $50,000 per year was based on the annual median household income in the U.S. of $50,502 in 2011[19]. The second model for this analysis also included online health information seeking as a proxy for patient engagement, and health tracking (both binary).

All analyses and characteristics of the sample were computed from the weighted sample after exclusion of missing diabetes or smartphone values (N=2989). The percentage of complete cases was 78%. Missing covariate data were infrequent (≤1.8%) other than for income (18.5%). Missing data were multiple-imputed with 25 imputed datasets using imputation by chained-equations[20]. The imputation model included the covariates used in all our analysis (with dependent variables), as well as three auxiliary variables: state, use of urgent care in the past 12 months and self-reported health. Categorical variables were compared using Chi-Square tests. P values from regression models were derived from Wald tests with robust standard errors. A p-value <0.05 determined statistical significance. Residual confounding was assessed by testing the effect modification of diabetes by age group. As smartphone use

is not a rare event, odds ratios do not approximate relative risks. To avoid misinterpretation of the results, we presented our results after conversion to relative risks using the margins function[2121212120] of Stata 11 (Stata Corporation, Texas).

Results

We describe the diabetic and non-diabetic populations in our sample (Table 1), with weighted descriptive analyses. Among the 2991 respondents, 332 had diabetes (weighted proportion of 11.1%). Individuals with diabetes were significantly older than non-diabetic participants (mean age of 59.9y vs 45.5y, p<.001, Table 1). They also had more comorbidities (hypertension, congestive heart failure and other chronic diseases such as asthma or cancer). Gender and ethnicity were not different, but more participants with diabetes were of Black race than participants without diabetes (16.9% vs 12.7%). Socio-economic status was lower in the diabetic group, with fewer insured participants, lower educational attainment, a lower income and a higher prevalence of unemployment. Compared with non-diabetics, individuals with diabetes had a significantly higher feature phone use (50.6% vs 38.3%, p<.001 Table 1) and a lower smartphone use (20.7% vs 48.6%, p<.001). About half of the patients with diabetes used email and Internet, compared with over three quarters of individuals without diabetes. Moreover, five out of six participants with diabetes tracked at least one health parameter (diet, weight, carbohydrates, etc.), compared with two thirds of non-diabetics (p<.001). Individuals with diabetes had a lower use of health applications on smartphones (3.8% vs 10.0%, p=.002).

In Table 2, we report the characteristics of smartphone users in our sample (both diabetic and non-diabetic individuals included) compared with non-smartphone users. This latter group includes individuals who use feature phones and/or landlines. The sample comprised 1360 smartphone users (weighted proportion 45.5%) and 1629 non-smartphone users (1185 feature phone users and 444 individuals with only landlines, weighted proportions 39.6% and 14.8% respectively). The landline only population was older, with more comorbidities: they had the highest prevalence of diabetes (21.4%), compared with feature phone users (14.2%) and smartphone users (5.0%). They had a higher proportion of Caucasians (81.2%) and Hispanics (16.1%) than the feature phone and smartphone users, and had lower educational attainment. They had lower use of email and Internet. Gender was not significantly different among these groups.

(The smartphone user group includes users of both smartphone and landline phones)

Compared to White participants, Asian participants had a significantly higher use of smartphones (Table 2). The smartphone population also had significantly higher income, employment rate and higher educational attainment than the non-smartphone population. The proportion of uninsured did not differ with smartphone use. Finally, use of emails and Internet was almost universal in the smartphone group (92% and 98% of individuals, respectively), compared to less than two thirds of the non-smartphone group. Two thirds of the participants tracked some health parameter, regardless of the type of phone technology.

The results of the primary analysis comparing the use of smartphone between diabetic and non-diabetic participants are presented in Table 3. In the unadjusted analysis, individuals with diabetes were less likely to use smartphones compared with those without diabetes (RR 0.43, 95% CI 0.31 to 0.54, p<.001). After adjusting for age, individuals with diabetes were still less likely to be smartphone users compared with those without diabetes (RR 0.58, 95%CI 0.40 to 0.75, p<.001). In the full model that adjusted for race, ethnicity, income and education level (potential confounders), participants with diabetes remained significantly less likely to be smartphone users compared with those without diabetes (RR 0.78, 95% 0.57-0.98, p=0.05). In this multivariate model, we also observed that Blacks, Asians and Hispanics were more likely to use a smartphone than Caucasians and non-Hispanics, respectively. We also found strong evidence that a higher income and education attainment was positively associated with smartphone use. There was no significant residual confounding by age in the adjusted analysis.

The results of the secondary analysis of predictors of smartphone use among individuals with diabetes are shown in Table 4. In the multivariate model 1, younger age and higher income were strongly associated with smartphone use, whereas race/ethnicity and education were not. Model 2 further explored online health seeking behavior and health tracking behavior. Individuals who sought health information online were more likely to be smartphone users (RR 3.68, 95% CI 1.06-6.30, p<.001). The individuals who tracked health parameters, however, were *less* likely to be smartphone users (RR of 0.62, 95%CI 0.36-0.88, p=0.04).

Discussion

In our nationwide sample, we found that individuals with diabetes were less likely to be smartphone users compared with individuals without diabetes, even after adjusting for potential confounding by age, SES, race and ethnicity.

The pattern of lower use among the older population is consistent with market studies on smartphone adoption[1, 22]. Although early evidence supports the long-term effectiveness of mobile technologies in diabetes self-management with improved HbA1c values after 6 months[9] and 12 months[10], our results suggest that these technologies might not be appropriate for all individuals, and efforts to improve standard care in diabetes self-management should continue to include more traditional contacts with patients including in-person and standard telephone communications.

Understanding lower smartphone use among individuals with diabetes is important, as healthcare delivery systems are likely to move towards a higher use of smartphone applications for diabetes self-management. Diabetes, its long-term complications and related comorbidities can lead to physical and cognitive impairments, such as lower dexterity from neuropathy or visual impairments. All these unmeasured factors are barriers to smartphone use, and are all accentuated by older age. Despite the slow increase in smartphone uptake among older adults, the very rapid uptake among younger adults may accentuate the age gap in smartphone use. The trend towards larger screens of newer devices (phablets, mini-tablets and tablets) and improved usability are promising approaches to address visibility and dexterity impairments related to diabetes and age[23, 24]. Finally, care-providers might also have a role to play in diffusing diabetes applications to patients who already use smartphones[25], as they already provide guidance for websites and online communities to their patients[26]. Our findings support further research on understanding the differences in the use of smartphone use among patient with diabetes.

The 51 to 64 year-old age group may benefit the most from smartphone-based interventions for diabetes, as it is the second fastest growing age group for smartphone uptake[12]. We found that one in six individuals in this age group currently used smartphones. With over a million individuals from this age group newly diagnosed with diabetes each year in the U.S.[2], the potential reach of smartphone-based interventions should not be overlooked, particularly for the early stages of disease[27]. Smartphone interventions have the potential to lower HbA1c values effectively, (e.g., mean HbA1c reduction of 1.9% in the smartphone group vs 0.7% in the usual care group (P=0.001) over 12 months)[10]. Any 1% reduction in HbA1c is associated with significant reduction of the risk for myocardial infarction (14%) and stroke (12%)[28]. Furthermore, not only does the benefit of HbA1c reduction increase over time, the reduction in all-cause mortality is greater when the HbA1c reduction occurs early in the disease[29].

As smartphone use is highest among young adults, it may offer unique opportunities for early diabetes self-management or diabetes prevention. Most diabetes applications provide tracking tools to monitor health parameters, and can guide early disease management, making these tools particularly useful at early stages of disease)[3, 27]. In addition, the reach of smartphones among racial/ethnic minorities might allow early prevention by supporting behavior change in this subpopulation with higher prevalence of early type 2 diabetes, in particular among adolescents.

In contrast to the age gap, smartphones have greater potential to help bridge the typical “digital divide” in Internet and computer access in racial and ethnic groups. The higher smartphone use by Blacks, Asians and Hispanics compared to Whites and non-Hispanics, reflect the importance of race and ethnicity for smartphone use[1, 16]. This finding has two important implications: (1) smartphones might be a new approach to improve access to high quality care for diabetes in racial/ethnic minority groups, and (2) future diabetes applications need to take cultural differences into consideration in their design. For instance, only a few diabetes applications currently offer the option of Spanish. Also, most applications or websites do not include options for cultural preferences in their food plans. One possible design implication could be to integrate more culturally adapted nutrition facts in smartphone applications to facilitate the adoption and adherence to diabetes-friendly food plans in this racial/ethnic minority groups.

Contrary to our hypothesis of smartphone use for health tracking, we found that individuals were less likely to be a smartphone user if they monitored their own health. Nearly two thirds of our participants tracked some health parameter, regardless of phone type. Individuals with diabetes predominantly have type 2 diabetes and do not use insulin, and therefore do not require highly intensive health tracking. In a prior study, patients seemed to categorize many of their health results as normal or abnormal, rather than recall the exact values, and therefore are content to check with little or not tracking[27, 30]. They tended to use traditional tracking methods (pen and paper, or websites) according to a recent survey[26]. Smartphones offer a wide range of features, and are not primarily adopted for health tracking purposes. This underlines the gap in assessing overall smartphone use rather than the use of diabetes-related applications. Furthermore, there is a delay in the diffusion of diabetes applications among smartphone users, and the use of pervasive technologies in smartphones to effortlessly track health.

Strengths and Limitations

One of the strengths of this paper is its secondary use of a dataset collected to study mobile health. It uses a random sample of landline and cellphone users from the national U.S. population, without targeting any disease in particular. This helps avoid the bias related to successful diabetes self-management. The survey was also conducted in two languages, English and Spanish, which facilitate participation from the rapidly growing Hispanic population.

Although the prevalence of diabetes in this sample (11.1% after weighting) is comparable to the prevalence of diabetes among U.S adults, a limitation of this study is its use of self-reported diabetes, as undiagnosed diabetes is estimated to be about a third of cases in the United States[2]. This limitation could contribute to the lack of association seen between smartphone use and race/ethnicity among individuals with diabetes. Furthermore, the survey did not differentiate between type 1 and type 2 diabetes. Yet type 2 is more prevalent among older adults and in lower SES populations[15]. The low survey response rate for both the landline and cellphone samples may also limit the generalizability of our findings. Moreover, this dataset only provided information about self-reported diabetes, without information about type of disease. Future studies should explore the association between disease duration, severity (HbA1c and comorbidities) and type of treatment (insulin use) and smartphone use.

Implications

Smartphones have generated great interest for patient empowerment, and bear potential in improving diabetes self-management in particular. Although the exponential growth of smartphone adoption now affects all age groups, this growth remains moderate among older individuals with lower income. Individuals with diabetes are older and have lower income than the general population: they therefore remain less likely to have a smartphone than individuals without diabetes. So although it is important for clinicians to be familiar with smartphone tools for diabetes, especially for subgroups of younger, newly diagnosed individuals or those from racial/ethnic minorities, we underline the importance of pursuing efforts to improve traditional diabetes care (in-person visits and phone calls) at this time. Further research is needed to understand this gap in smartphone adoption in the diabetic population, both in terms of access to the devices as well as for usability and design (font and screen sizes, for example).

Conclusion

This study is, to the best of our knowledge, the first report on the characteristics of smartphone users in a population of patients with diabetes. Compared to individuals without diabetes, smartphone use remains significantly less likely among individuals with diabetes. Since smartphones have the potential to improve self-management support for diabetes care, further research is needed to better understand this gap in smartphone use, in particular to address diabetes- and age-related differences. Our findings also emphasize the potential of smartphones to help prevent diabetes in younger adults, and to improve access to care for racial and ethnic minorities.

Analyzing U.S. prescription lists with RxNorm and the ATC/DDD Index

Olivier Bodenreider, MD, PhD, Laritza M. Rodriguez, MD, PhD
Lister Hill National Center for Biomedical Communications, National Library of Medicine, National Institutes of Health, Bethesda, MD

Abstract

***Objectives**: To evaluate the suitability of the ATC/DDD Index (Anatomical Therapeutic Chemical (ATC) Classification System/Defined Daily Dose) for analyzing prescription lists in the U.S. **Methods**: We mapped RxNorm clinical drugs to ATC. We used this mapping to classify a large set of prescription drugs with ATC and compared the prescribed daily dose to the defined daily dose (DDD) in ATC. **Results**: 64% of the 11,422 clinical drugs could be precisely mapped to ATC. 97% of the 87,001 RxNorm codes from the prescription dataset could be classified with ATC, and 97% of the prescribed daily doses could be assessed. **Conclusions**: Although the mapping of RxNorm ingredients to ATC appears to be largely incomplete, the most frequently prescribed drugs in the prescription dataset we analyzed were covered. This study demonstrates the feasibility of using ATC in conjunction with RxNorm for analyzing U.S. prescription datasets for drug classification and assessment of the prescribed daily doses.*

1. Introduction

Medication errors have been identified as a significant cause of mortality in hospitalized patients [1] and medication safety remains an important issue today [2]. Medication dose errors are a specific category of medication errors [3]. Large variations can be observed in prescribed doses, some of which correspond to medication dose errors, including tenfold medication dose errors [4]. One strategy for reducing medication errors, including dose errors, is to use Computerized Physician Order Entry (CPOE) systems offering clinical decision support [5]. The information used for clinical decision support in CPOEs generally comes from proprietary drug knowledge bases.

The Anatomical Therapeutic Chemical (ATC) classification of drugs is widely available and provides basic information such as drug classification and defined daily doses. This information may be insufficient to fully assist prescription, but can be used for analyzing a prescription dataset retrospectively. One typical use of ATC is to measure drug utilization for pharmaco-epidemiology purposes. However, most of the published studies leveraging the classification and defined daily doses features of ATC have been performed in Europe (e.g., [6-8]).

ATC was recently integrated in RxNorm. While RxNorm only integrates the terminological features of ATC, and not its defined daily doses and routes of administration, this integration already facilitates the analysis of prescription lists indexed with RxNorm identifiers, by providing a reliable entry point into ATC.

The objective of this study is to assess the suitability of the ATC/DDD Index (Anatomical Therapeutic Chemical (ATC) Classification System/Defined Daily Dose) for analyzing prescription lists in the U.S. More specifically, we propose to analyze drug classification based on ATC groupings and to compare the prescribed daily dose to the defined daily dose in ATC for a large prescription dataset from Surescripts. To our knowledge, this study is the first application of ATC to the analysis of a U.S. prescription dataset.

2. Background

This investigation leverages ATC, RxNorm and a large prescription list obtained from Surescripts.

2.1. ATC

The Anatomical Therapeutic Chemical (ATC) classification [http://www.whocc.no/atc_ddd_index/], a system developed by the World Health Organization (WHO) Collaborating Centre for Drug Statistics Methodology, is recommended for worldwide use to compile drug utilization statistics. The system includes drug classifications at 5 levels; anatomical, therapeutic, pharmacological, chemical and drugs or ingredients. Also included are defined daily doses (DDDs) and administration routes assigned to most drugs in accordance to the therapeutic and pharmacological groups.

For example, as shown in Figure 1, drugs from the "Digitalis glycosides" 4th-level group are included in the anatomical group "Cardiovascular system". The route of administration (Adm.R) and the defined daily dose (DDD) are listed for each of the four 5th-level drugs.

C CARDIOVASCULAR SYSTEM
C01 CARDIAC THERAPY
C01A CARDIAC GLYCOSIDES
C01AA Digitalis glycosides

ATC code	Name	DDD	U	Adm.R	Note
C01AA01	acetyldigitoxin	0.2	mg	O	
C01AA02	acetyldigoxin	0.5	mg	O	
C01AA03	digitalis leaves	0.1	g	O	
C01AA04	digitoxin	0.1	mg	O	
		0.1	mg	P	
C01AA05	digoxin	0.25	mg	O	
		0.25	mg	P	

Figure 1. Drugs from the Digitalis glycosides 4th-level group in ATC (partial screenshot from the ATC website)

The active ingredients in the classification include a wide range of chemical entities used in a variety of countries. New ingredients are not included in the ATC system until they are approved for pharmaceutical use in at least one country. Only herbal medicinal products approved by regulatory authorities are included in the classification.

The active moieties are classified according to the main therapeutic use of the main ingredient. Since an ingredient can have therapeutic applications on different anatomical sections, ATC assigns a different code to the same ingredient in different anatomical sections. For example, the beta-blocker *timolol* has different codes when used as a cardiovascular drug (*C07AA06*) and as a treatment for glaucoma (*S01ED01*).

The defined daily dose (DDD) is the assumed average maintenance dose per day for a drug used for its main indication in adults. The DDD is calculated based on adult weight of 70 kg. The DDD can be an average of doses from different countries and might the reflection of the more commonly used strengths. The DDD is not necessarily the prescribed daily dose, as the latter depends on individual patient characteristics such as age, weight and pharmacokinetic considerations. Topical products, sera, vaccines, antineoplastic agents, allergen extracts, anesthetics and contrast media are not assigned a DDD.

The 2014 edition of ATC used in this study contains 4580 5th-level ATC drugs, of which 3904 correspond to single-active moieties (as opposed to combinations).

2.2. RxNorm

RxNorm is a standardized nomenclature for clinical drugs compiled from 12 drug source vocabularies, and maintained by the National Library of Medicine (NLM). A clinical drug is defined as a pharmaceutical product with therapeutic or diagnostic properties available to patients. A clinical drug includes the ingredient(s), strength or concentration, and dose form appropriate for the intended administration route (e.g., *Thyroglobulin 32 MG Oral Tablet*). The February 2014 edition of RxNorm is used in this study.

Base ingredients are the active moieties of clinical drugs (e.g., *amoxicillin*). RxNorm also covers their various salts, esters and complexes (e.g., *amoxicillin trihydrate*), referred to as "precise ingredients" in RxNorm parlance. Unlike RxNorm, ATC represents mostly base ingredients and does not distinguish between base and precise ingredients. Single-ingredient drugs have a unique chemical component, and multiple-ingredient drugs have two or more (e.g., *Amoxicillin 250 MG / Clavulanate 125 MG Oral Tablet*). While drug combinations are precisely defined in RxNorm, they are often unspecified in ATC (e.g., *meprobamate, combinations*).

Dose forms are administration vehicles, such as pills, tablets, syringes and lotions. Dose form groups (DFGs) are grouping of dose forms (DFs). For example, the DFG *Oral Product* includes the DFs *Oral Tablet, Oral Capsule, Chewable Tablet*, etc. RxNorm DFGs roughly correspond to administration routes in ATC.

RxNorm identifies a subset of drugs intended to be an approximation of the prescription drugs currently marketed in the U.S. We refer to this subset as the "prescribable subset" of RxNorm drugs, and use it as to restrict our analysis to the most clinically significant drugs.

Ingredient-level mapping between RxNorm and ATC. Since August 2013, ATC is a source vocabulary in RxNorm, which provides a mapping between RxNorm ingredients and 5th-level ATC drugs. Of the 3166 RxNorm single ingredients (base and precise), 1552 (49%) mapped to a 5th-level ATC drug, corresponding to 1991 ATC codes and 1554 distinct ATC drug names. These ingredients in common represent 51% of the 3904 5th-level ATC drugs, ignoring drug combinations.

Since the scopes of RxNorm and ATC are slightly different, the mapping is not expected to be complete. For example, RxNorm includes several hundred allergenic extracts (e.g., *papaya allergenic extract 50 MG/ML Injectable Solution*) that are out of the scope of ATC. Conversely, diagnostic and therapeutic radiopharmaceuticals (e.g., *technetium (^{99m}Tc) bicisate*) are present in ATC (under *V09* and *V10*), but out of the scope of the prescribable subset of RxNorm.

In contrast to RxNorm, in which each ingredient is represented only once, ATC can have multiple codes for the same active moiety, depending on the anatomical system or therapeutic domain in which it is used. As a consequence, there will often be multiple ATC mappings for a given RxNorm ingredient. For example, the RxNorm ingredient *Ketoconazole* (*6135*) maps to the following ATC codes for this drug: *D01AC08* (from the *ANTIFUNGALS FOR DERMATOLOGICAL USE* group), *G01AF11* (from the *GYNECOLOGICAL ANTIINFECTIVES AND ANTISEPTICS* group) and *J02AB02* (from the *ANTIMYCOTICS FOR SYSTEMIC USE* group).

2.3. Surescripts dataset

The prescription drug list is a de-identified list comprised of 102,709 clinical drugs dispensed to emergency room patients over a period of three months in 2011 at Suburban Hospital in Bethesda, Maryland. Each drug includes an anonymized prescription identifier, clinical drug name, drug form, strength, prescribed amount, and the intake duration. This prescription list was annotated with RxNorm identifiers for clinical drugs. When updated against the February 2014 version of RxNorm, 99,576 drugs were valid (or could be mapped to a valid code), while 3133 were obsolete. Of these, we only investigate the 87,001 drug codes corresponding to single-ingredient drugs from the prescribable subset of RxNorm.

2.4. Related work

Many studies have been published reporting on drug utilization based on ATC for various classes of drugs, including antibiotics [9, 10], cardiovascular drugs [8], and anti-depressants [11], or across classes [7]. Some studies specifically compare prescribed daily doses to defined daily doses in ATC for anti-epileptic drugs [6] and for several classes of anti-hypertensive drugs [12]. One characteristic of most of these studies is that they were performed in Europe, where ATC is more widely used than in the U.S.

More recently, ATC has also been used as a terminological reference for drugs. For example, ATC has been used to support the detection of adverse events in the EU-ADR project [13]. Additionally, ATC has been used as a reference in research projects where drug classes were predicted by integrating chemical-chemical interactions and similarities [14] or through text mining [15]. In earlier work, we compared and contrasted ATC with the National Drug File-Reference Terminology (NDF-RT) developed by the U.S. Department of Veterans Affairs (VA) Veterans Health Administration [16].

The specific contribution of our work is the application of ATC in combination with RxNorm, the standard drug vocabulary in the U.S. While many pharmaco-epidemiology studies leveraging ATC have been published in Europe, to the best of our knowledge, this study is the first analysis of a prescription dataset in the U.S. with ATC and RxNorm.

3. Methods

In ATC, a 5th-level code is assigned not to an ingredient, but to an ingredient for a specific therapeutic intent. For example, the beta-blocker *timolol* can be used orally or parenterally as a cardiovascular drug (*C07AA06*) and in eye drops as a treatment for glaucoma (*S01ED01*). Moreover, a defined daily dose (DDD) is assigned not to an ingredient, but to an ingredient with a specific route of administration. For example, the DDD for *acetylsalicylic*

acid is 3 g for oral forms, but 1 g when administered parenterally. As a consequence, for the purpose of finding the DDD, the mapping of RxNorm clinical drugs to ATC requires a match for both the ingredient and the route of administration. Our approach to comparing the prescribed daily dose to the defined daily dose is depicted in Figure 2. While the ingredient-level mapping is provided by RxNorm, we had to create a mapping for the routes of administration in order to relate RxNorm clinical drugs to their appropriate ATC 5th-level code. We then mapped clinical drugs from the prescription dataset to RxNorm and computed the prescribed daily dose for comparison to the corresponding defined daily dose in ATC.

In this investigation, we restrict the scope of the mapping to single-ingredient clinical drugs in RxNorm and ATC, because combination drugs are often underspecified in ATC. For example, the ATC 5th-level code *N05BC51* corresponds to *meprobamate, combinations*, and is distinct from the single-ingredient category for *meprobamate* (*N05BC01*), but without specifying which ingredients can be associated with *meprobamate* or what the DDD for *meprobamate* is in this case. Moreover, since our goal is to analyze prescription lists, we restrict the mapping to clinical drugs from the prescribable subset of RxNorm. Finally, since the prescribed daily dose is not explicitly mentioned in the Surescripts data, we further restrict the comparison of daily doses to oral solid dose forms of clinical drugs, for which we can rely on RxNorm to extract the quantity per prescription dose (i.e., pill).

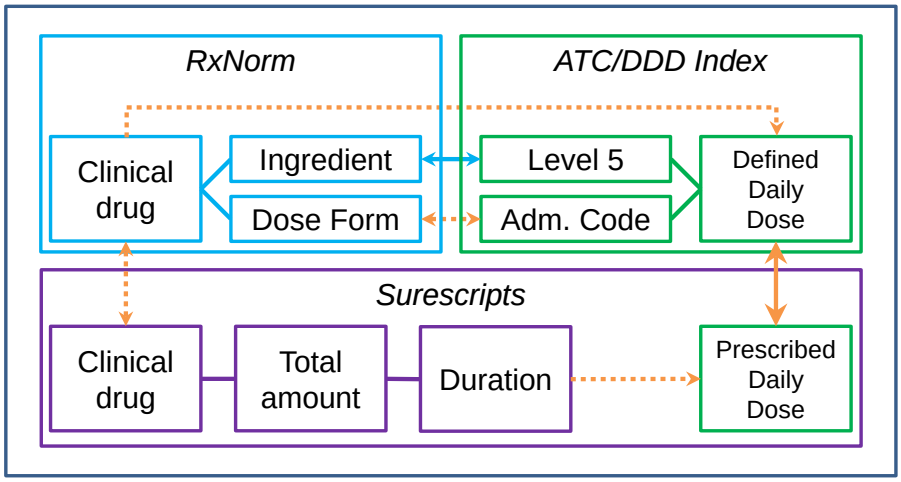

Figure 2. Overview of the methods for comparing the prescribed daily dose to the defined daily dose

3.1. Mapping RxNorm clinical drugs to ATC

In order to support our use cases of drug classification and assessment of prescribed daily doses, the mapping of RxNorm clinical drugs to ATC must account for both the ingredient and the route of administration. More specifically, we define a mapping between a clinical drug in RxNorm and an ATC 5th-level drug when the following two conditions are met.

1. The ingredient (active moiety or salt ingredient) of the clinical drug in RxNorm maps a 5th-level drug in ATC. We use the ingredient-level mapping provided in RxNorm.
2. The dose form group for the clinical drug in RxNorm and the administration code (or one of the administration codes, if multiple) of the 5th-level drug in ATC are compatible. (i.e., are associated through the same administration route), as defined below.

For example, as illustrated in Figure 3, the RxNorm clinical drug *Amoxicillin 25 MG/ML Oral Suspension* (*313797*) maps to the ATC code *J01CA04* (*amoxicillin*), because the ingredient of the RxNorm clinical drug, *amoxicillin*, maps to this ATC code, and the dose form group of the RxNorm clinical drug, *Oral Product*, matches one of the routes of administration for the ATC code *J01CA04*, *O*, through the administration route *oral*. In contrast, despite the fact that both drugs have the same ingredient, *butoconazole*, we failed to map *5000 MG Butoconazole nitrate 20 MG/ML Prefilled Applicator* (*890780*) to *G01AF15*, because the dose form group of RxNorm drug, *Prefilled Applicator Product*, is not listed as compatible with the vaginal route, *V*, listed for this drug in ATC. Finally, some

RxNorm drugs have no mapping to ATC because their ingredient is simply not present in ATC (e.g., *oregano allergenic extract 50 MG/ML Injectable Solution*).

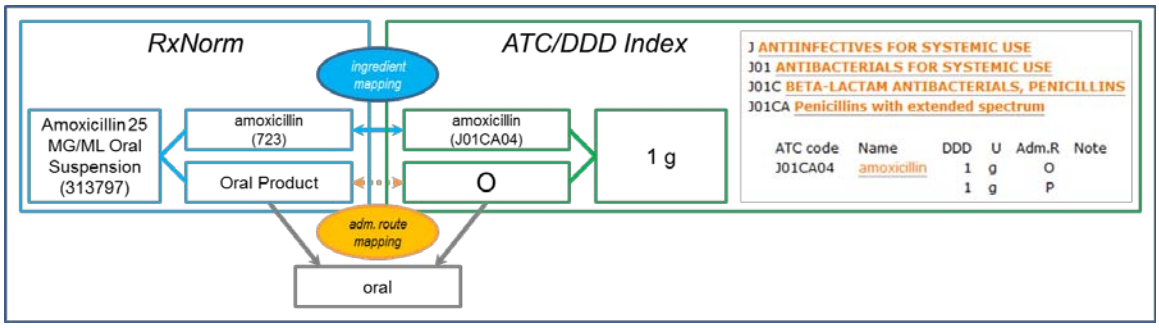

Figure 3. Mapping between RxNorm and ATC through both the ingredient and the route of administration

Mapping routes of administration between RxNorm and ATC. In order to map routes of administration between RxNorm and ATC, we harmonized the dose form groups in RxNorm and the administration codes in ATC. We also assigned administration codes to ATC drugs when they were missing.

Harmonization of administration codes between RxNorm and ATC. RxNorm and ATC have different ways of representing routes of administration. In RxNorm, the route is expressed through the dose form group (DFG), but RxNorm DFGs actually represent the dose form (e.g., *Pill*), the route (e.g., *Ophthalmic Product*) or a mix of both (e.g., *Oral Gel Product*). Many clinical drugs are associated with multiple DFGs, typically one for the dose form and one for the route. For example, *Ketoconazole 200 MG Oral Tablet* (*197853*) is associated with both *Pill* and *Oral Product*. Of the 45 DFGs in RxNorm, 22 represent dose forms exclusively, but some of them are indicative of topical products nonetheless (e.g. *Shampoo Product*).

ATC assigns administration codes to the drugs in scope for the defined daily dose (e.g., *O* for oral, *N* for nasal, etc.). In addition to the 22 administration codes, ATC defines 10 coarser administration routes. Although ATC does not provide a correspondence between administration codes and administration routes, this correspondence is usually trivial to establish. Missing from the list of ATC administration routes are entries for the routes of ophthalmologic, otic, stomatologic and other topical products, for which ATC typically does not provide DDDs.

We extended the list of 10 administration routes from ATC with *ophthalmologic*, *otic*, *stomatologic* and *topical*, adding *urethral*, as it exists as an administration code. We mapped all relevant DFGs from RxNorm to the extended list of 15 administration routes derived from ATC.

Assignment of missing administration codes in ATC. As mentioned earlier, one issue for mapping drugs between RxNorm and ATC is that ATC assigns administration codes only to a subset of its drug entities, as required for the DDD. In practice, drugs for which no DDD is asserted are also missing an administration code. These drugs typically include topical products and systemic drugs for which there are large inter-individual dose variations (sera, vaccines, antineoplastic agents, allergen extracts, general and local anesthetics and contrast media).

For these drugs, we used various strategies to semi-automatically infer an administration code when it was missing. More specifically, we manually created rules to assign administration codes to sets of drugs based on various characteristics, so that missing administration codes could be automatically inferred at the level of individual drugs. These rules were applied in the following order.

1. The authors assigned one or more administration code manually, not to individual drugs, but to specific ATC groups (at various levels), based on clinical knowledge (e.g., the group *Enemas* (*A06AG*) was associated with the administration route *rectal*).
2. The authors assigned one or more administration code manually based on specific expressions found in the labels of ATC groups (e.g., ATC drugs from groups, whose label contain the expression “systemic” were associated with the administration routes *oral* and *parenteral*).

3. All administration codes found in the drugs for a given 4th-level ATC group were propagated to the drugs with missing administration codes in the same group (e.g., the drug *alogliptin* (*A10BH04*) "inherits" the administration code *oral* from the other drugs in the group *Dipeptidyl peptidase 4 (DPP-4) inhibitors* (*A10BH*), namely *sitagliptin*, *vildagliptin*, *saxagliptin*, and *linagliptin*).
4. The administration code *oral* was assigned by default to any digestive drug (e.g., the digestive drug *tilactase* (*A09AA04*) was assigned the administration code *oral*).
5. The administration code *topical* was assigned by default to any drug that has not been assigned one in the previous steps (e.g., the drug *tetracycline* (*D06AA04*) was assigned the administration code *topical*).

3.2. Analysis of the Surescripts prescription dataset

The Surescripts prescription dataset is coded to RxNorm clinical drugs and we use the mapping to ATC in order to be able to classify the prescription drugs with ATC groups and to compare the prescribed daily doses to the defined daily doses listed in ATC.

Assessing coverage. The proportion of RxNorm clinical drugs from the Surescripts dataset to which we can associate a specific ATC 5th-level code (i.e., accounting for both the ingredient and the route of administration) assesses the coverage of RxNorm clinical drugs in ATC.

Classifying prescription drugs. Through the mapping to ATC we extract the ATC classification of the drugs for characterizing the prescription list. For example, the RxNorm clinical drug *sitagliptin 50 MG Oral Tablet* (*665042*) maps to the 5th-level ATC drug *A10BH01*, classified under the diabetes drugs in the ATC level-1 group *A*.

Assessing prescribed daily doses. We also compare the prescribed daily doses to the defined daily doses listed in ATC. In the Surescripts dataset, the prescribed daily dose is not explicitly provided. From the total number of prescription doses and duration of the prescription, we can calculate the number of prescription doses for a day. We then use RxNorm to get the quantity in each clinical drug. For example, a prescription of 45 doses *Clonazepam 0.5 MG Oral Tablet* for 30 days yields a prescribed daily dose of .75 mg (.5 * 45 / 30). Of note, for comparability between drugs, RxNorm normalizes the strength of solutions per milliliter, of inhalers per "puff" for metered-dose inhalers, and of topical creams and gels to mg/mg. As a consequence, the normalized quantity reflected in RxNorm often does not correspond to the prescribed dose. For this reason, we restrict the analysis of prescribed daily dose to oral solid drug form drugs from the Surescripts dataset. We also ignore from the dataset RxNorm drugs for which ATC provides more than one DDD for a given route of administration.

3.3. Implementation

From a technical perspective, this investigation can be thought of as a data integration project. The datasets to be integrated include RxNorm, ATC, the ingredient mapping between RxNorm and ATC, and the mapping of both RxNorm dose form groups and ATC administration codes to administration routes, as well as the prescription dataset. Semantic Web technologies are known to provide support for data integration. Here we converted all the datasets to the Resource Description Format (RDF triples) and loaded them into the triple store Virtuoso. The query language for RDF, SPARQL, also provides support for writing production rules (of the "if … then" type). We created production rules in order to infer the missing administration codes. We also created rules to infer the mapping of clinical drugs to ATC. Finally, we queried the integrated dataset in order to export the prescribed and defined daily doses for each prescription for statistical analysis.

4. Results

4.1. Mapping RxNorm clinical drugs to ATC

Of the 11,422 single-ingredient clinical drugs from the prescribable subset of RxNorm, 7748 (68%) had an ingredient mapping to ATC, and 7260 (64%) had both an ingredient and an administration route mapping. In other words, a mapping between a clinical drug in RxNorm and a drug in ATC (at the 5th level) for a particular administration route was found for 64% of the clinical drugs in RxNorm.

These RxNorm clinical drugs mapped to 1912 unique ATC codes (96% of the 1991 ATC codes to which an ingredient mapping was found) and 1479 unique drug names (95% of the 1554 ATC drug names to which an

ingredient mapping was found), corresponding to 49% of the 3904 ATC codes for single active moieties (and 44% of the drug names).

Harmonization of administration codes between RxNorm and ATC. The correspondence between RxNorm DFGs, ATC administration codes and the extended administration routes is shown in Table 1. Each of the 22 dose form groups from RxNorm and each of the 24 administration codes from ATC (including the four codes we created) is mapped to one of the 15 administration routes (extended list). As a result, each dose form group from RxNorm can be associated with at least one administration code from ATC.

Table 1. Correspondence between RxNorm dose form groups and ATC administration codes through then extended list of administration routes derived from ATC.

RxNorm Dose Form Group	Route of administration	ATC Administration Code
Drug Implant Product	*implant*	implant s.c. implant
Inhalant Product	*inhalation*	Inhal Inhal.solution Inhal.powder Inh.aerosol Inhal.aerosol Instill.sol.
Nasal Product	*nasal*	N
Oral Product	*oral*	O Chewing gum oral aerosol
Ophthalmic Product	*ophthalmic*	lamella [ophthalmic] *
Otic Product	*otic*	[otic] *
Injectable Product	*parenteral*	P
Rectal Product	*rectal*	R
Sublingual Product	*sublingual/buccal*	SL
Buccal Product Dental Product Oral Cream Product Oral Foam Product Oral Gel Product Oral Ointment Product Oral Paste Product	*stomatologic*	[stomatologic] *
Transdermal Product	*transdermal*	TD TD patch
Intraperitoneal Product Irrigation Product Mucosal Product Prefilled Applicator Product Shampoo Product Soap Product Topical Product	*topical*	intravesical ointment [topical] *
Urethral Product	*urethral*	urethral
Vaginal Product	*vaginal*	V

** added to the original ATC administration codes for mapping purposes*

Assignment of missing administration codes in ATC

Of the 3904 5th-level codes in ATC for single active moieties, 2059 (53%) are missing an administration code. The distribution of the number of ATC codes for which administration codes were generated is listed in Table 2, by type of technique. Since the rules for ophthalmic, otic, stomatologic and rectal products were allowed to generate administration codes even when one had been asserted by ATC, the total number of ATC drugs for which administration codes were generated is slightly higher than the number of ATC codes with missing administration codes.

Table 2. Number of ATC codes for which administration codes were generated automatically, by type of technique.

Expression in ATC group label	#
Administration code inferred from ATC group	725
Adminisstration code inferred from expressions found in the labels of ATC	232
Administration code inferred from drugs from the same ATC group	492
Oral admistration code inferred by default (digestive drugs)	23
Topical administration code inferred by default (remaining drugs)	643
Total	2115

4.2. Analysis of the Surescripts prescription dataset

Assessing coverage. Of the 87,001 RxNorm codes from this Surescripts dataset (restricted to single-ingredient drugs from the prescribable subset of RxNorm), 84,380 (97%) mapped to at least one code in ATC (through both the ingredient and the route). Moreover, of the 1695 distinct RxNorm clinical drugs found in the Surescripts dataset, 1606 (95%) were found in ATC.

Classifying prescription drugs. Using the mapping to ATC, we classified the 84,380 prescriptions from the Surescripts set against the top-level categories in ATC, resulting into 86,578 ATC codes. The distribution of Surescripts drugs by top-level ATC groups is shown in Figure 4. The top categories are cardiovascular and nervous system drugs. Of note, some RxNorm clinical drugs map to more than one code in ATC (e.g., drugs with multiple therapeutic uses for the same route of administration, such as *clonidine hydrochloride 0.3 MG Oral Tablet*, used orally as both as an antihypertensive drug (*C02AC01*) and an antimigraine agent (*N02CX02*)).

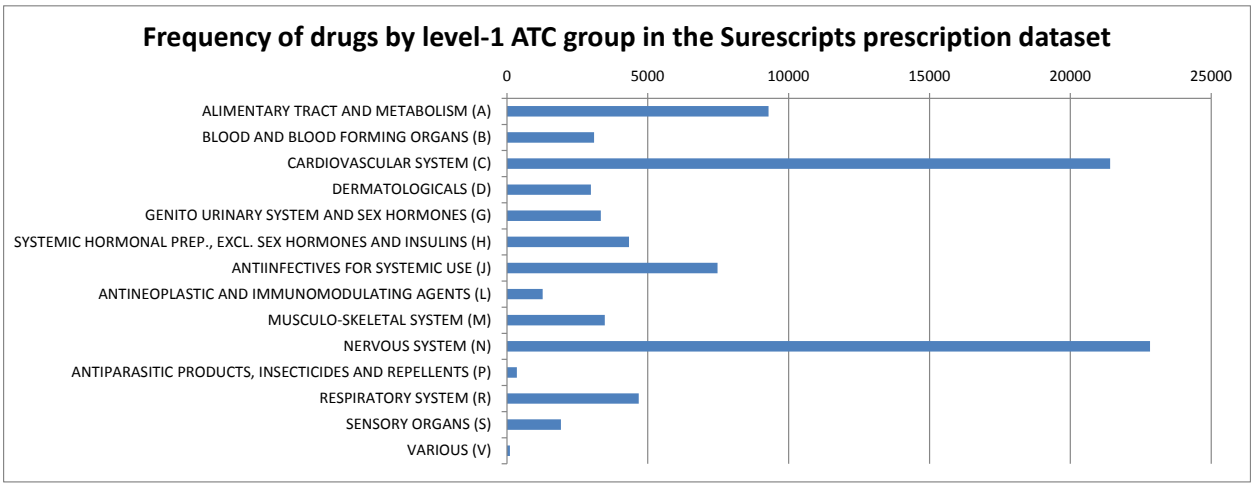

Figure 4. Distribution of Surescripts drugs by top-level ATC groups

Assessing prescribed daily doses. Of the 72,360 RxNorm clinical drugs corresponding to oral solid dose forms in the Surescripts dataset, 70,394 (97%) could be associated with a defined daily dose in ATC, of which 1932 were associated with more than one DDD (and were ignored from the comparison). For the remaining 68,462 drugs, we compared the prescribed and defined daily doses. The distribution of the ratios of the prescribed daily doses (PDDs) to the defined daily doses (DDDs) is plotted in Figure 5 (using a logarithmic scale, because of the amplitude of the variation among the ratios). Overall, the PDD exactly matches the DDD in 28.6% of the prescriptions. The ratio is in a 66%-150% range for 49.5% of the prescriptions, in a 50%-200% range for 76.1%, and in a 33%-300% range for 86.1%. Only 3.4% of the PDDs are beyond 300% of the DDD and 10.4% below 33% of the DDD. The proportions covered by each range are shown in Figure 5.

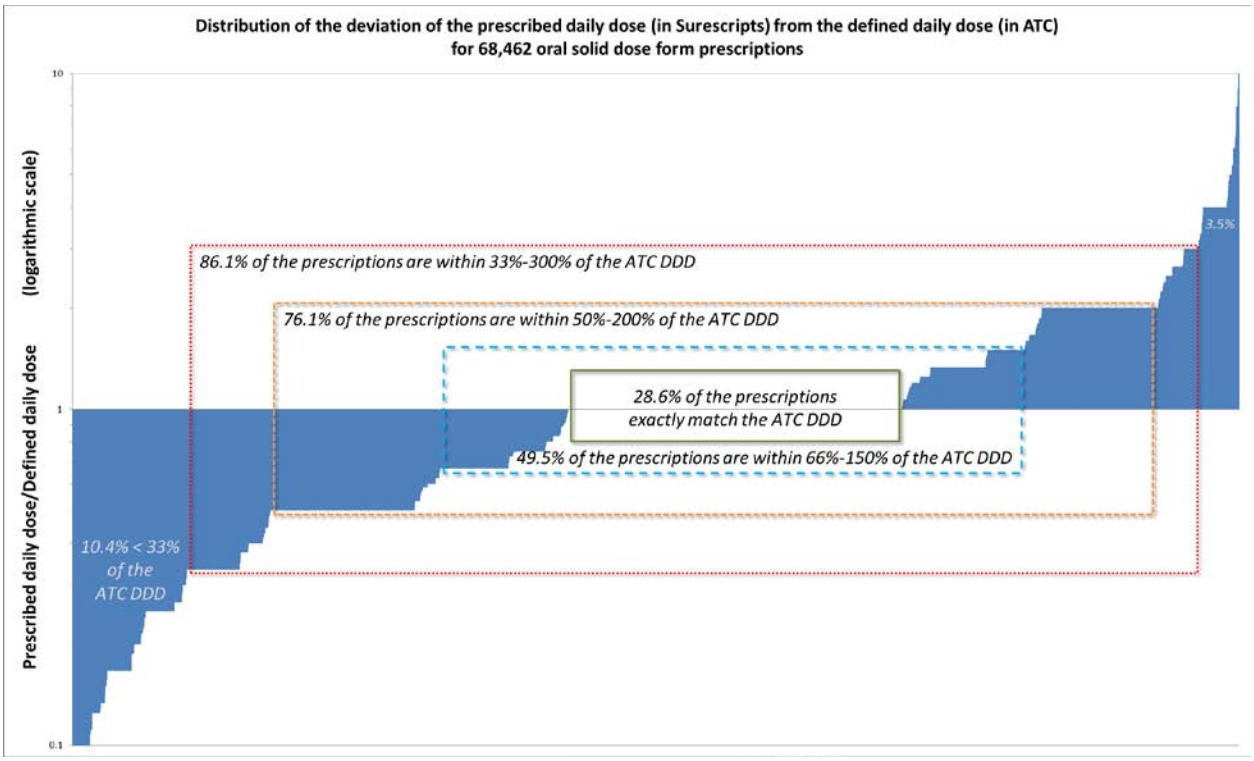

Figure 5. Distribution of the deviation of the prescribed daily dose from the defined daily dose

5. Discussion

Significance. Although the overall coverage for ingredient mapping is limited, we were able to demonstrate that prescription drugs in current use in the U.S. are mapped reliably and in a considerable proportion. This study confirms that the use of ATC in conjunction of RxNorm is a valid strategy for analyzing prescription datasets in the U.S., both from the perspective of classifying drugs and for the comparison of prescribed and defined daily doses. While ATC is routinely used in Europe for pharmaco-epidemiology, our study is the first application of ATC to prescription data in the U.S.

Limitations. The main limitation of our work is the limited size and scope of the prescription dataset, in which the variation of drug ingredients is necessarily limited, even more so in the case of drugs from emergency room patients only. While the proportion of clinical drugs mapped to ATC may be smaller in other datasets, the method of mapping to ATC through RxNorm should be generally applicable, including when drugs are represented with codes from the National Drug Code (NDC) or not coded at all. Another limitation is that the analysis of the prescribed daily doses was restricted to oral solid dose forms, because the prescribed dose was not explicitly mentioned in the Surescripts dataset and could not be reliably extracted from RxNorm. In fact, this issue is being addressed in RxNorm by creating different entities for solution with identical (normalized) concentrations, but different quantities per volume (e.g., 1 mg/ml and 5mg/5ml).

Future work. In addition to the exploration of larger and more diverse prescription datasets, the focus of future work is to refine the administration route assignment for missing routes in the ATC, allowing for more precise mapping. We also would like to combine two aspects of the current work, i.e., drug classification and deviation from the defined daily dose, in order to investigate whether certain classes of drugs tend to be prescribed at higher or lower doses compared to the defined daily dose.

6. Conclusions

Although the mapping of RxNorm ingredients to ATC appears to be largely incomplete, the most frequently prescribed drugs in the prescription dataset we analyzed were covered. This study demonstrates the feasibility of using ATC in conjunction with RxNorm for analyzing U.S. prescription datasets for drug classification and assessment of the prescribed daily doses.

Abstract

Authors studied the United States (U.S.) Department of Veterans Affairs' (VA) Virtual Lifetime Electronic Record (VLER) Health pilot phase relative to two attributes of data quality - the adoption of eHealth Exchange data standards, and clinical content exchanged. The VLER Health pilot was an early effort in testing implementation of eHealth Exchange standards and technology. Testing included evaluation of exchange data from the VLER Health pilot sites partners: VA, U.S. Department of Defense (DoD), and private sector health care organizations. Domains assessed data quality and interoperability as it relates to: 1) conformance with data standards related to the underlying structure of C32 Summary Documents (C32) produced by eHealth Exchange partners; and 2) the types of C32 clinical content exchanged. This analysis identified several standards non-conformance issues in sample C32 files and informed further discourse on the methods needed to effectively monitor Health Information Exchange (HIE) data content and standards conformance.

Introduction

Through the Virtual Lifetime Electronic Record (VLER) Health Exchange initiative, the United States (U.S.) Department of Veteran Affairs (VA) can electronically share parts of Veterans' health records with providers at the U.S. Department of Defense (DoD), and participating private sector health care organizations (exchange partners). As a direct benefit to Veterans, doctors involved with their care would have a more comprehensive and timely record of health information, including services received by the Veteran outside of their purview. VLER Health Exchange leverages the policies and technical standards of the eHealth Exchange (formerly the Nationwide Health Information Network or NwHIN) supported by the non-profit, public-private collaborative called Healtheway [1, 2]. Goals include better informed care providers, improved continuity and timeliness of care, enhanced awareness among all parties, and elimination of gaps in a patient's health record.

VA engaged in a pilot of VLER Health Exchange to comprehensively test and improve health data standards for effective exchange of Veteran health information across the eHealth Exchange [3, 4]; to establish models for nationwide health information exchange (HIE); to identify scalable implementation strategies; and to assess early impacts of VLER Health Exchange. VA selected 12 sites with a strong business case for HIE and sought a diversity of characteristics, such as geographic factors (e.g., rural, urban), populations served, the maturity of the HIE organization, and their sustainability models. Four pilot sites participated in a three-way exchange between VA, DoD, and the private sector, and eight sites participated in two-way exchange between VA and the private sector. The pilot period concluded in October 2012. A more in-depth description of the VLER Health initiative and lessons from the pilot phase are reported elsewhere [5]. After satisfactory completion of the pilot phase, Veterans Health Information Exchange has been expanded nationally, connecting to more and more private sector partners and enabling clinicians at all VA Medical Centers to see externally sourced data.

As the policies and technical systems that serve as the foundation for nationwide HIE continue to mature, and the amount of health data and documents being shared across the eHealth Exchange increases, greater attention is now focused on the quality of data exchanged [6]. Data quality issues impact the way in which the

data reach the intended recipients, are realized in the user interface and, for many user systems, incorporated by the Electronic Health Record (EHR). The exchange of health information between the numerous products and versions of EHR systems requires a standardized method for communicating data that is agreed upon and adopted by entities seeking to share data. During the VLER Health pilot, eHealth Exchange Partners shared data through use of a suite of data transport tools and services called CONNECT. The primary health data standards used to structure the exchanged data included the Health Information Technology Standards Panel (HITSP) C32 and C62 document standards [7].

C32 documents use the Health Level 7 (HL7) Continuity of Care Document (CCD) component to describe the content of a health summary to be created, exchanged, and to summarize a patient's medical status. The content may include administrative (e.g., demographics, insurance) and clinical information (e.g., problem list, medication list, allergies and test results) [8]. C32 content standards are comprised of 17 content modules that represent the underlying clinical data in both narrative and structured forms. In addition to C32 structured documents, C62 documents can be used to incorporate unstructured clinical notes and scanned documents (e.g., text file, PDFs, or images such as a scanned image of an electrocardiogram) [9].

The technical hurdles of matching patient records, exchanging data from different EHR systems and geographies and then properly rendering the data in a manner that can be effectively used by health care providers are significant. Within the data standards themselves, including the C32, issues of optionality and interpretation create differences in the way the standards are implemented and the way data are mapped across systems. Consequently, even the most diligent HIE development and implementation can produce challenges that hinder effective health data exchange.

The VLER Health pilots and HIE initiatives that preceded VLER Health established an important baseline of understanding as it relates to the adoption and implementation of eHealth Exchange health data standards, and the availability and quality of clinical content of shared Veterans within pilot regions [10, 11, 12].

Methods

Effective sharing of Veteran health information across the eHealth Exchange requires export and import of a validated C32 document with health information. Our study methods established a baseline for two attributes of data quality: 1) compliance of exchange partner's C32 to current data standards; and 2) the clinical content being provided within VLER Health documents exchanged. Addressed in the first are issues of data quality that occur at the structural level of the C32 exchanged by partners. The second evaluates the types of content, or richness, of information exchanged.

Validation of C32 Data Standards Compliance

All eHealth Exchange partners must comply with the current eHealth Exchange standards. The eHealth Exchange onboarding process during the pilot phase required exchange partners to be able to produce a compliant C32, but did not include formal compliance and content testing. The National Institute of Standards and Technology (NIST) Clinical Document Architecture (CDA) validator was used to validate potential eHealth Exchange partner C32's for conformance to the HITSP/C32 v2.5 standard. The NIST CDA validator tests the underlying Extensible Mark-up Language (XML) within the C32 to determine whether the schema and data provided conform to the requirements established by the HITSP/C32 v2.5 specification.

For this study, the NIST CDA validation application was downloaded from the NIST website, installed locally and configured with the libraries necessary to check the validity of C32 documents per v2.5 specifications. The HITSP/C32 specification consists of an evolving hierarchy of standards for electronic documentation of health information, including services received by a patient (e.g., Continuity of Care Record (CCR), HL7 CDA, CCD, HITSP C32).

The NIST CDA validator reports the types of non-conformances found in each related section and classifies non-conformance alerts with the current C32 standard into levels of severity that include errors (items of non-conformance), warnings (items that technically conform, but could be better constructed), and notes (general comments and suggestions on implementation). Should a part of the C32 being tested not conform, a report is provided that outlines where and why an error occurred according to the specification (Figure 1).

These errors in the underlying XML of the C32 when realized on the screen can produce gaps in the information and reduces the quality of the data experienced by the care provider (Figure 2).

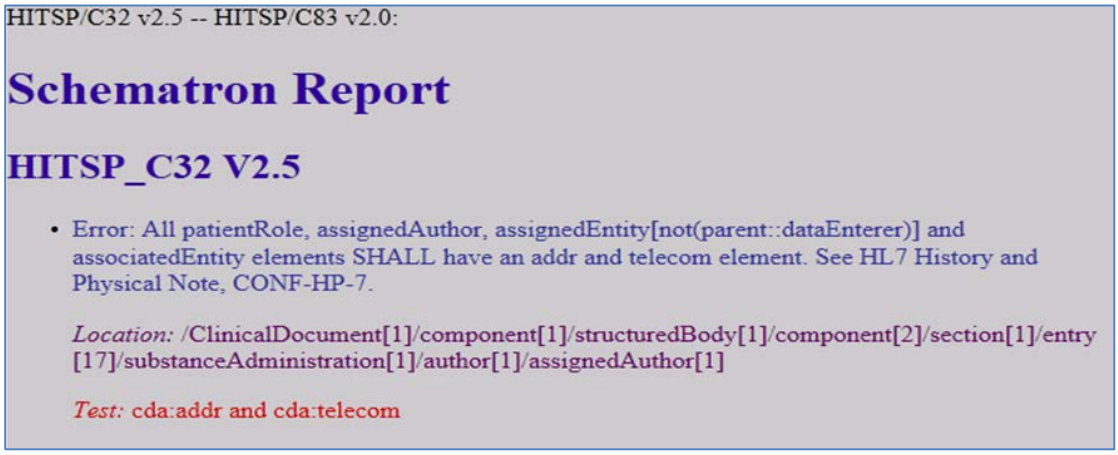

Figure 1. Example of NIST CDA Validation Schematron Report of a sample C32 document with errors

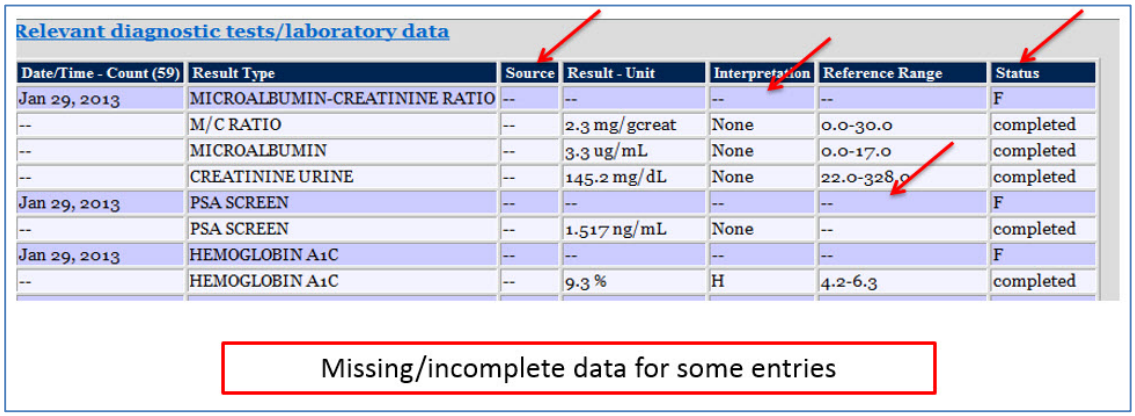

Figure 2. Example of errors in the C32 XML structure when realized in VA VistAWeb EHR

A sample of fourteen populated C32s provided between October 2011 and July 2012 were tested for their conformance to the current C32 standard - one from each of the 12 pilot site private exchange partners' EHRs and one from the VA and DoD systems. Test results recorded when non-conformance to the specification was found and where (e.g., CDA, CCD), the types of non-conformance identified (e.g., missing data element or attribute), and the sections in which the non-conformances were found (e.g., header, problems/conditions, medications). This assessment only considered those classified by the NIST CDA validator as potential errors in the C32 structure.

Evaluation of C32 Data Content Availability

The clinical content of the C32 was also assessed to better understand the type and amount of clinical data available to and from VA providers during the VLER Health pilot. In July 2012, tests of VLER Health pilot clinical content were conducted by VA as a part of an operations and quality assurance initiative. VA partner C32s were analyzed based on data available between October 2011 and June 2012.

Based on a random sample of 250 Veterans with records available for exchange for each VLER Health pilot site partner, C32s were queried using VistAWeb, and the types of content available were analyzed (e.g., medications, laboratory results, procedures). Eight of the twelve pilot site exchange partners, plus VA, were included in the study, providing a total of 2,250 Veteran records for analyses. Partners that were not included in this sub-study were either not in production or lacked a sufficient number of matched patients at the time the study was conducted.

For each retrieved C32 document, the populated modules were recorded. The study measures consisted of: 1) whether a C32 was returned for each Veteran; 2) for retrieved C32s, whether the Veteran had any eHealth Exchange clinical data available in their populated C32; and 3) if so, the types of clinical modules were populated. Testers only examined whether each C32 clinical module (e.g., medications) contained data, but did not review the C32 for other attributes of the data content such as completeness, display issues or data quality.

Results

VLER Health Exchange Partner C32 Validation

Validation analysis of eHealth Exchange partner C32s indicated that six of the VLER Health exchange partners produced conformant validation results. The other eight C32s tested, however, resulted in some level of error being reported when run through the NIST CDA validator. Two of the C32s tested produced over 10 unique errors of non-conformance to the standard (often the same error is repeated multiple times depending on the content present in the C32). Issues encountered were primarily related to undefined attributes or XML pattern errors, problems found within the document header, and missing data elements or required values as defined by the C32 standard.

It is important to note that the majority of issues identified would not necessarily impact the way in which clinical content was reported. Many issues were due to administrative attributes of the clinical document (e.g., proper inclusion of a country code) that are important to broad health information exchange, but may not be critical to a patient's treatment. A person viewing this information in an EHR may not even perceive the impact of these types of errors, but as established by the HITSP C32, these specifications are deemed important and mandatory for proper inclusion, and consequently may result in incompatibilities and errors when shared among C32-compliant software.

Outlined in Table 1 are the categories, definitions, and error types for 103 issues identified across eight of the 14 C32s analyzed. As noted previously, depending on how many records are present in the C32, these issues can be reproduced many times, but represent only one main issue in how the C32 is constructed. The frequency of issues is important in terms of the user experience when viewing the document on their screen.

Table 1. Validation Issues Identified in VLER Health Partner C32 Samples

Issue Categories	Definitions	Percent of total issues (n=103)	Prevalence
Non-conformant Attribute or Pattern	An XML attribute or pattern that is unrecognizable by the rules and requirements provided by the C32 schema	10%	Found at least once in 5 partner C32s, with over 200 different instances found
General Header Constraints	Important details regarding the origins and author of the record may be missing or improperly described	58%	Found at least once in 8 partner C32s, with over 300 different instances found
Missing Elements or Required Values	Required data elements and/or coding missing or improperly represented in the C32	32%	Found at least once in 8 partner C32s, with over 200 different instances found
Source: Based on 14 sample C32s, one from each of the VLER Health exchange partners provided between October 2011 and July 2012.			

Non-conformance issues were most commonly found in the medication, insurance, laboratory result, allergy, and problem modules. This fact may only be because these were the modules reported most frequently for the C32s tested, or because information for some clinical modules are not sent at all by a particular eHealth Exchange partner at the time of the study.

Types of Clinical Content eHealth Exchange Partners are Capable of Sharing

Of the nine eHealth Exchange partners whose C32s were analyzed for clinical content (eight private partners and VA), the majority of C32s (88 percent) included clinical content in addition to basic demographic data. Table 2 provides a breakdown of clinical content data availability among VLER Health exchange partners by C32 module, the average of C32s that were populated with data for that module, and the range of results across exchange partners.

Table 2. Data Availability for VLER Health Partners by C32 Module

C32 Module	Percent of C32s Populated	Range Populated by Partner
Demographics	100%	100%
Providers	86%	71% ~ 99%
Problems	84%	52% ~ 99%
Allergies	74%	13% ~ 99%
Encounters	74%	35% ~ 94%
Medications	63%	<1% ~ 97%
Vital Signs	53%	1% ~ 80%
Laboratory Results	46%	9% ~ 81%
Procedures	42%	9% ~ 61%
Immunizations	35%	2% ~ 63%

Source: Based on a sample of 250 C32s for nine exchange partners (including VA) at the time of the evaluation, plus VA, retrieved July 2012. (n=2,250)

Note: Tests were conducted in July 2012 as a VLER Health quality assurance/operations study. The disclosures are for the period 10/13/2011 - 7/25/2012.

Given the patient matching processes needed to exchange clinical data, basic demographics information was available in 100 percent of the C32s retrieved. This was expected given that demographics information is required for patient matching and exchange of a C32, which were part of the inclusion criteria for this analysis. Provider information was available in 86 percent of the records. Problem list, allergy list, encounters, medications, and vital signs were also available in more than half of the C32s tested. When analyzing the C32s by VLER Health Partners, problem list, allergy list, and medications remain the most commonly available data module; three VLER Health Partners sent these data for more than 75 percent of their Veterans, and another four VLER Health Partners sent these data for at least half of their Veterans.

Subgroup analysis comparing VLER Health Partners shows that problems and allergies were populated the most frequently (seven out of nine partners), followed by medications and laboratory test results (6 out of 9 partners), followed by list of encounters and list of procedures (5 out of 9 partners). Half of VLER Health Partners were able to send at least eight clinical modules, and nearly all VLER Health Partners could send at least five clinical modules, including problem list, allergy list, medication, laboratory test results, and procedures data.

Discussion

The HL7 Consolidated CDA (C-CDA) is the current standard promoted by Meaningful Use 2014, however at the time of the VLER Health pilot the HITSP C32 summary of care record was elected to be the template used to exchange health information through a national-level HIE. The C32 had yet to be implemented and tested in a large-scale, geographically dispersed, production-level exchange. By implementing the C32 standard in a live patient-care environment with multiple exchange partners through the VLER Health program, VA experienced how "optionality" in the specifications can lead to differences of interpretation, uncertainties of implementation, and incompatibilities among compliant software. The NIST CDA validator identified many non-conformance issues in sample C32 files. However, the issues are not reflective of unpracticed adoption of the standards; rather are reflective of the optionality and flexibility in interpretation and implementation built into the standard. These data quality issues related to the implementation of health information standards can have significant implications in effective rendering of the data when sharing data between numerous partners and systems [13].

Although the NIST CDA validation system can help ensure compliance with the C32 specification, and therefore greater compatibility with the receiver's system, it did not yet assist with assessing clinical validity of this information. A small number of C32s were subsequently manually inspected to determine whether they conformed to HITSP specified standard terminologies. Use of clinical coding terminologies (e.g., Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT), Logical Observation Identifiers Names and Codes (LOINC)) helps to ensure semantic interoperability (i.e., meanings of terms and codes translate across systems) and can enhance quality and safety of decision making by clinicians. Results from this informal study suggest that use of clinical coding terminologies was relatively low (less than 30 percent of the terminology coding requirements were met), but further study of the use of data standards and terminologies by provider EHRs would provide more information about this attribute of data quality.

The study of clinical content availability only assessed whether a C32 data domain was present or not and did not assess the data structure, display, or clinical validity aspects that would further inform the usability of the data. As a part of general operations, VLER Health pilot sites compiled clinical content related quality issues (e.g., duplication of data, inconsistencies in formatting and display) based on anecdotes and observations by clinicians and VLER Health staff members when retrieving VLER Health data. The issues identified by VLER Health staff would likely go undetected by the NIST validation system and included problems related to the quality of the data (e.g., little or no clinical data available in the record), inconsistencies in the way the data were presented (e.g., the name of the medication not listed together with the medication allergy, excessive abbreviations, incorrect terminology mapping), and incomplete details that reduced the value of the information (e.g., missing reference ranges for laboratory test results). Further study at this last mile of HIE usability in which the data exchanged is acted upon by the care provider or system who receives the information is critical to understanding future requirements and priorities in health information standards development. VA has expanded its initial data quality assessment activities to include ongoing production validation and scoring of partner CCDs, including the above mentioned data quality aspects.

While significant challenges were encountered in the exchange of VLER Health data during the VLER Health pilot, it is also important to note that eHealth Exchange Partners were reliably providing a core set of valuable clinical content to VA clinicians. Tests confirmed that for sites that are in production and stable, eHealth Exchange data is retrievable for most VA correlated Veterans, and further, that clinical data are available for 91 percent of these correlated Veterans through eHealth Exchange. The VLER Health pilot has supported the VA to better understand the requirements necessary to effectively exchange health information across the eHealth Exchange and to develop a long-term strategy toward better interoperability of content. C32 standard conformance issues, clinical content availability, and the data presentation issues identified during the VLER

Health pilot helped inform VA's work with the Office of the National Coordinator (ONC) Standards and Interoperability Framework in shaping a more robust and interoperable C-CDA standard.

There are two noteworthy efforts to mention that will help construction and testing of more valid and interoperable content among eHealth Exchange partners. The first is the formal requirement that the new eHealth Exchange onboarding body has adopted for content testing. Healtheway guidance explains to implementers what content is required beyond the C32 to reach a meaningful exchange and how this content should be populated and will be tested. For instance, with HITSP, only the Person Information and the Source sections were required, whereas the Healtheway Bridge C32 will require Allergies, Medications, Problems, and Laboratory Results to also be populated [14]. This is further promoted by Meaningful Use Certification 2014. The second is the opportunity to consider alternative technical ways to implement structured document creation. For example, Model-Driven Health Tools (MDHT) is a project that develops structured document creation and evaluation tools that are programmatically derived and enforced from models of the specifications [15].

This study identified the need for improved models of validation and testing of exchange partner data content. Current NIST validation tools include validation guidelines for addressing Meaningful Use requirements for compliant CCDs. As the number of providers exchanging data across the eHealth Exchange increases, "turn-key" tools for validating clinical content for exchange will need to be devised and include strategies for ongoing monitoring and validation of clinical content and standards implementation. Study results have implications related to the complexity of health data interoperability, the evolution of health data exchange standards and its significance to policies such as those embodied in Meaningful Use [16]. In order to effectively comply with Meaningful Use 2014 Certification requirements and beyond, strict rules on validation are needed, and more consistent methods of testing should be established for providers and HIE organizations [17].

Conclusion

The VLER Health pilot served as a live, large-scale, production-level test of eHealth Exchange standards used to exchange clinical data nationally. VA and its partners experienced challenges in validating standards conformance, populating C32 documents, and presenting the data to providers in a consistently accurate, usable fashion. VA continues to work with DoD, Healtheway, ONC, and other stakeholders to leverage the VLER Health pilot experience to create better standards and tools needed by the nation as it moves beyond the barriers of connectedness in health care to the challenges of data integrity, quality, and usability.

Abstract

The potential of health information technology is hampered by new types of errors which impact is not totally assessed. OncoDoc2 is a decision support system designed to support treatment decisions of multidisciplinary meetings (MDMs) for breast cancer patients. We evaluated how the way the system was used had an impact on MDM decision compliance with clinical practice guidelines. We distinguished "correct navigations" (N+), "incorrect navigations" (N–), and "missing navigations" (N0), according to the quality of data entry when using OncoDoc2. We collected 557 MDM decisions from three hospitals of Paris area (France) where OncoDoc2 was routinely used. We observed 33.9% N+, 36.8% N–, and 29.3% N0. The compliance rate was significantly different according to the quality of navigations, 94.2%, 80.0%, and 90.2% for N+, N–, and N0 respectively. Surprinsingly, it was better not to use the system (N0) than to use it improperly (N–).

Introduction

Health information technology (HIT) is expected to improve the quality of care, reduce medication errors and adverse events, optimize overall health care utilization, and decrease costs. Electronic health records (EHRs), computerized provider order entry systems (CPOEs), and clinical decision support systems (CDSSs) are among the tools which can make the delivery of care safer, more effective and more efficient.[1] Whatever support these tools may provide, their relevance to healthcare and for healthcare professionals relies on the correct characterization of actual patients in EHRs and more widely in data repositories.

However, concerns about the quality of recorded patient data have been reported.[2] EHRs have become less reliable than ever before, flawed by errors introduced by medical personnel, patients, and machines.[3] Studies suggest HIT introduces unpredicted and unintended adverse consequences (UACs) potentially harmful for patients. Campbell et

al.[4] have identified 9 types of UACs resulting from CPOE implementation, the major of them being the Type 7 category (new kinds of errors) called "e-iatrogenesis" and defined by Weiner et al.[5] as "patient harm caused at least in part by the application of health information technology".

A US poll among health-care leaders revealed that HIT safety is the hazard of greatest concern for 2013.[6] Of those polled, 89% rated HIT patient/data mismatches in EHRs and HIT systems as a 9 or 10 on a scale of 1 to 10 as a hazard of great concern. In another more recent study, the most often safety event reported is that "Data is incomplete, missing or misleading" in EHRs (52%).* Patient data may thus be missing, incorrectly entered, badly displayed, and erroneously transmitted which may have serious safety consequences at the individual level. Apart from "technoskeptics", some authors consider that technology-related errors are due to the inappropriate use of HIT tools. For instance, Sittig and Singh[7] reported that UACs of HIT occur when HIT is unavailable for use, malfunctioning during use, used the wrong way, or when HIT interacts inadequately with another system component. Numerous patient safety initiatives for HIT are thus carried out to handle the issue of technology-induced errors.[8,9] Gaining knowledge on how to avoid misuse and promote correct usage becomes a requirement when implementing HIT tools to further secure their routine use.

Cancer management is subject to variable practices and to varied levels of compliance with oncology practice guidelines.[10,11] In the last decade, multidisciplinary meetings (MDMs), or tumour boards, have become a standard of practice to improve therapeutic decision quality of cancer patients. The underlying hypothesis is that the management of cancer is by nature pluridisciplinary, and that treatment plans collectively established by cancer specialists (surgeons, oncologists, radiologists, pathologists, radiotherapists, etc.) are better than those proposed by one specialist deciding alone. If studies on cancer care generally associate MDMs with improvements of guideline compliance rates,[12,13,14] the efficiency of MDMs has been recently questioned[15,16] and the debate is still open, suggesting there should be opportunities for decision support in MDMs.[17]

Many studies have indeed shown that clinical decision-support systems (CDSSs) might be effective tools to promote clinical practice guideline (CPG) compliance.[18] We have developed a guideline-based CDSS called OncoDoc2[19] to assist decision-making for non-metastatic breast cancer according to local (CancerEst) CPGs. OncoDoc2 has been routinely used for three years in the breast cancer MDM of a single hospital, showing very good results in terms of compliance rate.[20] More recently, a prospective cluster multicentered randomized controlled trial (RCT)† has been carried on to assess the impact of OncoDoc2 on the compliance of MDM decisions with CPGs. Six hospitals were randomized to separate the three hospitals of the "intervention arm" where OncoDoc2 had to be used during MDMs to decide the care plan of breast cancer patients, and the three hospitals of the "control arm" where MDMs proceeded as usual (OncoDoc2 was not used). This paper does neither discuss the methods nor present the results of the RCT, which will be presented in a different paper. The objective here is to focus on the use of OncoDoc2, and only analyze the intervention group according to the study design. In a previous work with the same context,[21] we studied the accuracy of actual data entry. When using OncoDoc2, we distinguished three different situations: "correct navigations" (*N+*), "incorrect navigations" (*N–*), and "missing navigations" (*N0*). The aim of this work is to evaluate how the way OncoDoc2 was used has an impact on the quality of MDM decisions assessed by their compliance with CPGs.

Material and Method

The OncoDoc2 CDSS. OncoDoc2[19] is a computerized guideline-based CDSS. It provides patient-specific recommendations for the management of any primary breast cancer (in situ and invasive) according to CancerEst (local) CPGs. The knowledge base is structured as a decision tree where nodes represent patient criteria, arcs represent values of criteria, and paths represent theoretical patient profiles. The system can be automatically run from patient data extracted from EHRs. It can also be used according to the document-based paradigm of decision-making where the decision tree is interactively browsed by a user. Thus, using OncoDoc2 consists in answering, by a simple click on the right value, a sequence of closed-ended questions, displayed in the interface, to finally access recommended care plans when the hypertextual navigation is completed and a leaf is reached. The user's navigation through the knowledge base, denoted N, instantiates criteria according to patient-specific data, which selects the theoretical clinical profile that best fits the actual patient, $N = \{criteria = value\}^*$. Figure 1 shows a screenshot of OncoDoc2 displaying a

navigation, characterized by a path of the decision tree ("Recapitulative"), and the corresponding recommendations ("CancerEst Recommended Treatment Plans"). If the MDM decision is one of the proposed recommendations, then the decision is compliant with the CPGs encoded in the system.

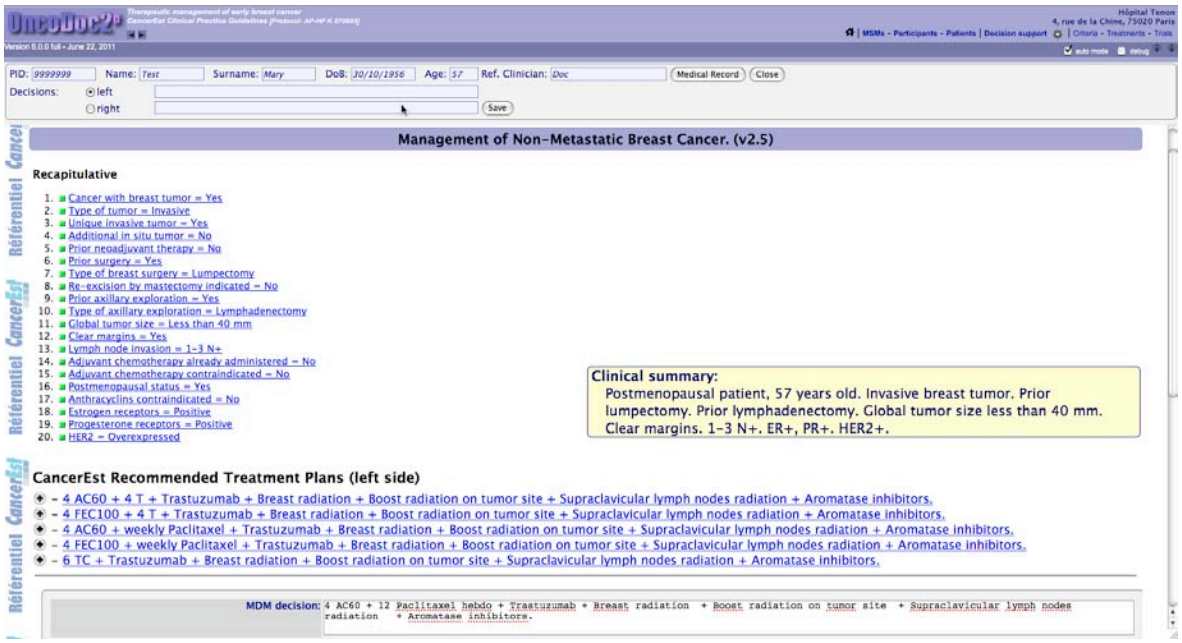

Figure 1. Screenshot of OncoDoc2: display of the patient profile selected by the navigation with clinical summary and corresponding recommendations.

Study background. The MDM is a common organizational feature of cancer care practice.[17] In France, it is one of the measures launched by the first National Cancer Program (2003-2007) and renewed in the second (2009-2013) and third (2014-2019) Programs. Multidisciplinary decision making have become mandatory for all cancer patients.

The six hospitals of the RCT are located in the eastern area of Paris (France). They all organize weekly breast cancer MDMs. In the three hospitals randomized to the intervention arm, MDM physicians had to use OncoDoc2 for all breast cancer patients. Navigations were either performed by one physician among MDM participants or by the MDM secretary. All were informed of the study and of its objectives, and trained to the use of OncoDoc2 before the study started. Navigations were performed while the clinical case was orally presented to MDM physicians. The display of OncoDoc2's interface was shown on a large screen so that all participants could follow the navigation performed and read the system's recommendations. In each hospital H_i, and for each discussed case P_{i_j}, the MDM navigation, N_{ij}^{MDM}, as well as the final therapeutic MDM decision d_{ij} were recorded in OncoDoc2 database.

Data collection. Each week and in each of the six hospitals of the RCT, clinical research assistants (CRAs) collected the data of all the patient cases discussed in MDMs the previous week. None of the hospitals were equipped with a full EHR. Thus, CRAs were given the list of the patients discussed along with their paper-based medical records. CRAs knew which hospitals were in the control arm, resp. the intervention arm, of the RCT, but they didn't know what were the navigations performed by MDMs of the intervention arm, and for each patient case of both arms, they blindly performed their own navigation on the basis of the information they found in paper-based records. CRAs had been previously clinically trained. In both arms of the RCT, MDM decision compliance was computed by the comparison of MDM decisions and the recommendations provided by CRA-performed navigations. For all MDM decisions computed as non-compliant, CRA navigations were reviewed, data were checked back in medical records,

and possibly corrected, by a domain expert. Thus, for each patient case P_{i_j}, the CRA-performed final navigation was considered as the "gold standard" and named "reference navigation" noted $N_{i_j}^{Ref}$. The set of recommendations attached to the reference navigation has been considered as the reference recommendations that apply to the patient and noted $\{R\}_{i_j}^{Ref}$. We stated that a MDM decision d_{i_j} was compliant with CPGs when it belonged to the set of recommendations of the reference navigation, *i.e.* $d_{i_j} \in \{R\}_{i_j}^{Ref}$. In this way, CRA data collection and analysis process was the same in both the intervention and the control arms.

Data analysis. We only considered for the analysis the data from the intervention arm, *i.e.* when OncoDoc2 was used. For each patient case P_{i_j} discussed during a MDM, we compared the MDM navigation $N_{i_j}^{MDM}$ with the reference navigation $N_{i_j}^{Ref}$. Depending on data entry quality when using OncoDoc2, we distinguished three types of decisions:

- Decisions made with "correct navigations" (*N+*): MDM navigations were identical to reference navigations.
- Decisions made with "incorrect navigations" (*N–*): MDM navigations differed from reference navigations. At least one criteria instantiation of the MDM navigation was different from its value in the reference navigation, and considered as a false data entry or an error.
- Decisions made with "missing navigations" (*N0*): Some MDM decisions didn't have a corresponding MDM navigation in OncoDoc2 database. In this case, the system might not have been used and MDMs did not complete the intervention as required by the protocol.

We first studied how comparable were the three samples of decisions using statistical monovariate analyses on patient criteria. We then analyzed the effect of data entry quality on the compliance of MDM decisions with CPGs. The special case of *N–* navigations has been analyzed. In particular, we studied the distribution of the data error rate among the decision criteria used by OncoDoc2. Some navigations were close enough to the reference navigation to include identical care plan recommendations: $\{R\}_{i_j}^{MDM} \cap \{R\}_{i_j}^{Ref} \neq \emptyset$. Such situation was qualified as $Recos^+$. In such cases, the recommendations provided by OncoDoc2 did include some guideline-based care plans actually recommended for the patient although she was not correctly described by the navigation performed by the MDM. On the contrary, when there was no overlap of the care plans proposed by the two navigations, $\{R\}_{i_j}^{MDM} \cap \{R\}_{i_j}^{Ref} = \emptyset$, none of the recommendation provided by OncoDoc2 was appropriate for the patient according to CPGs and this case was noted $Recos^-$. We made a difference between these two scenarios and assessed the effect of *N–* navigations leading to either $Recos^+$ or $Recos^-$ on the compliance of MDM decisions.

Results

MDM decisions were included between June 2009 and April 2010 (11 months). In this work, we only considered decisions made when OncoDoc2 was available for use, *i.e.* in the hospitals of the intervention arm. A total of 557 decisions were collected and considered for analysis. Hospital accrual was respectively of 73, 155, and 329 decisions for the 3 hospitals, H_1, H_2, and H_3.

Navigation types, data accuracy, and effect on decision compliance. We collected 189 decisions *N+* (33.9%), 205 *N–* (36.8%), and 163 *N0* (29.3%). In the subset of 394 (189 + 205) decisions where MDM navigations were available, we observed 52.0% of incorrect uses *N–*. When considering data entry of MDM users of OncoDoc2, 6,025 criteria assignments were performed, 15.3 per decision in average. A total of 252 data entry errors were identified in incorrect navigations *N–*, yielding an overall error rate of 4.2% of all clinical data entry.[21]

The overall compliance rate of the 557 decisions was measured at 87.8% in an intent-to-treat analysis, *i.e.* independently of MSMs fully following the study protocol and using the CDSS, or not, thus taking all *N0* decisions into account. Compliance rates according to the navigation type are reported in Table 1. They were measured at 94.2%, 80.0%, and 90.2% for *N+*, *N–*, and *N0* decisions respectively, and were significantly different ($p < 10^{-4}$, Chi^2, simple

descriptive statistics, no cluster effect taken into account). The compliance rate is the highest when the system is correctly used (*N+*). It is improved when the system is not used (*N0*) as compared to when it is incorrectly used (*N–*).

Table 1. Distribution of compliance rates by navigation type, and hospital accrual.

	N+	*N–*	*N0*		*Total*
	N=189 (33.9%)	*N=205 (36.8%)*	*N=163 (29.3%)*	p	*N=557*
Compliance					
Yes	178 (94.2%)	164 (80.0%)	147 (90.2%)	$< 10^{-4}$	489 (87.8%)
No	11 (5.8%)	41 (20.0%)	16 (9.8%)		68 (12.2%)
Hospital					
H1	32 (16.9%)	26 (12.6%)	15 (9.2%)	$< 10^{-14}$	73 (13.1%)
H2	79 (41.8%)	66 (32.2%)	10 (6.1%)		155 (27.8%)
H3	78 (41.2%)	113 (55.1%)	138 (84.6%)		329 (59.1%)

Table 1 also reports the distribution of navigation types among hospitals. Results show a highly significant difference between hospitals ($p < 10^{-14}$, Chi^2). H_1, H_2, and H_3 have respectively 20.6%, 6.5%, and 41.9% of *N0* decision. H_3 was the main provider of decisions (59.1%), and brought 84.6% of all missing navigations *N0*. Data entry accuracy was 55.2%, 54.5%, and 40.8% for H_1, H_2, and H_3 respectively.

Comparison of decision characteristics by navigation type. Patient profiles were analyzed and compared to identify whether some criteria could be associated with navigation types. A first analysis consisted in comparing the decision criteria used in the reference navigations of the three samples of navigation types. Sixty-three criteria were used in *N+*, 64 in *N–* and 69 in *N0*. Among all these criteria, 60 were common to the three groups but with different frequencies of usage. A few criteria were specific of a navigation type. For instance, "Type of neoadjuvant chemotherapy" has only be used once, and in a *N+* navigation. The same applies to "Suspicion of invasive cancer" only used twice in *N–* navigations. More interestingly and despite they were used no more than twice each, the following criteria were only used in *N0* decisions: "Prior radiotherapy", "Factors of bad prognosis", "Size of the largest invasive tumor larger than 2 cm", "Pleiomorphic lesion". These decision criteria do usually characterize rather complex or unusual clinical situations.

A second analysis consisted in monovariate analyses of variables characterizing the patient, the tumor, or the decision with respect to the navigation type. Table 2 lists the variables usually used to describe cancer patients along with the variables significantly associated with the navigation type. "Bilateral cancer", "Prior breast cancer", and "Contraindication to radiotherapy" were significantly more frequent in *N0* decisions, although "Contraindication to radiotherapy" is correlated with the variable "Prior breast cancer". These characteristics correspond to less frequent conditions and might characterize decisions which are more complex than usual ones. Larger tumors ("Size of the largest nodule", "Cumulative tumor size including spaces") were more frequent in *N–* navigations.

Results for incorrect navigations (*N–*). In this group, there was at least one error in the navigation's data entry. The compliance rate was the lowest, 80.0% on 205 decisions.

These incorrect uses of OncoDoc2 were also analysed according to the fact that the recommendations provided by the system for erroneous patient profiles included ($Recos+$), or not ($Recos-$), care plans recommended in the reference navigation. For the 121 $Recos+$ navigations among 205 (59.0%), the compliance rate was 90.1%, whereas it was 65.5% for the remaining 84 $Recos-$ navigations. Compliance rates in $Recos+$ and $Recos-$ were significantly different ($p < 10^{-4}$, Chi^2).

A total of 252 data entry errors were collected in *N–* navigations. Eighty percent of these navigations had only one error, 18% had exactly 2 errors and 2% had exactly 3 errors. None had more than 3 errors. On the 51 decision criteria that were used in incorrect *N–* navigations, 39 (76.5%) were recorded with at least one error in data entry. Figure 2 shows the list of criteria sorted by their data entry error rate, which ranges from 55% to 1%.

Table 2. Main patient and tumor characteristics by navigation type.

Variables		*N+* *N=189, N (%)*	*N–* *N=205, N (%)*	*N0* *N=163, N (%)*	*P-value*

Note: Subtotals may differ from sample size due to missing data. Monovariate analyses were performed with Chi^2 tests for categorical data and Kruskal-Wallis tests for numerical data. Significance level chosen at 5%.

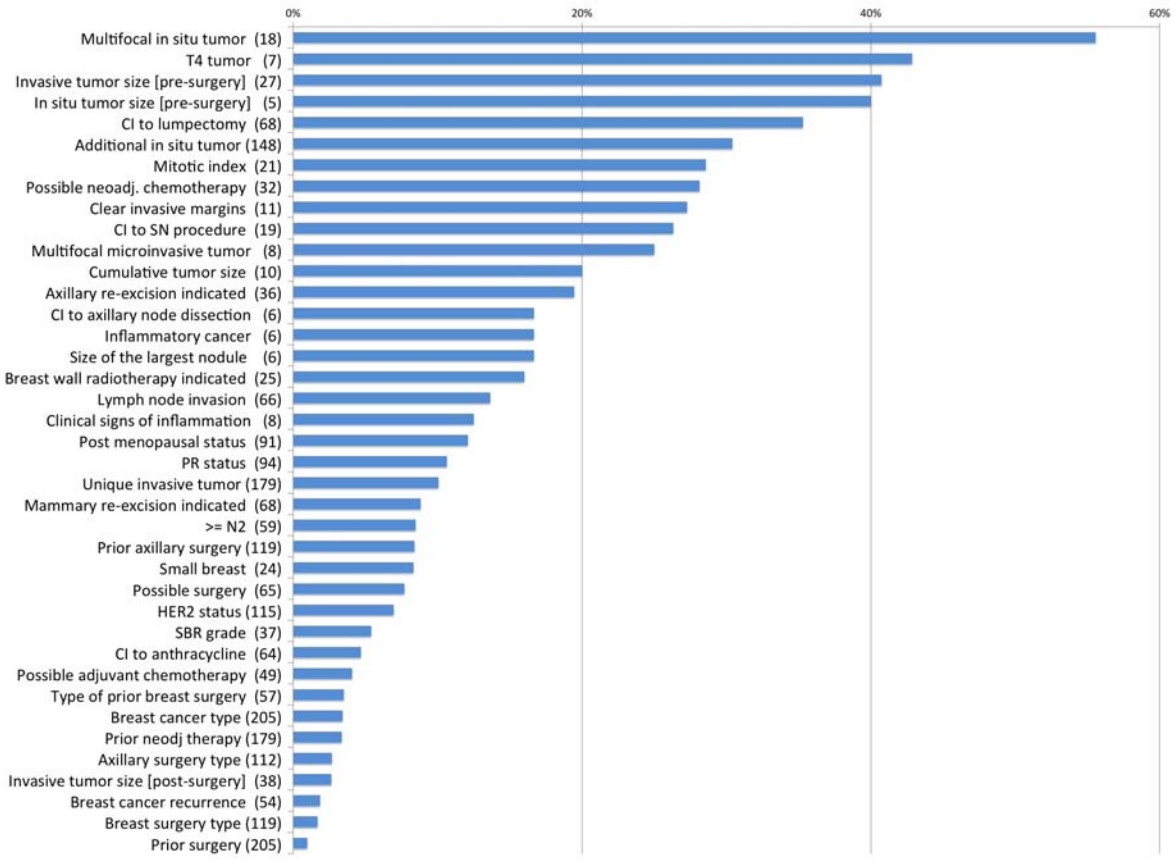

Figure 2. Decision variables involved in data entry errors of *N*– navigations, with their number of assignments and error rate.

Results for missing navigations (*N0*). For 163 decisions, there was no MDM navigation recorded in OncoDoc2 database. The compliance rate in this group, measured at 90.2%, was however higher than for incorrect navigations (*N*–), although lower than for correct navigations (*N*+).

Figure 3 displays the proportion of *N0* decisions by month of the study and by hospital. For H_1, all but one decisions were concentrated in the last 2 months where they represented 100% of MDM decisions, indicating a stop in OncoDoc2 recording for this hospital. In the other two hospitals, *N0* decisions are regularly distributed along the inclusion period, even if the proportions in H_2 and H_3 are different as previously noted.

Discussion and conclusion

Results show that the compliance rate of MDM decisions with CPGs is significantly associated with the navigation type, with compliance rates of 94.2% , 80.0%, and 90.2%, for correct (*N*+), incorrect (*N*–), and non uses (*N0*) of OncoDoc2.

We first studied whether the three samples of decisions associated with navigation types corresponded to different breast cancer patients. Many usual breast cancer variables were not significantly different among the three decision groups. However, there were significantly more patients with bilateral breast cancers or cancer recurrences in *N0* decisions and tumor size was significantly higher in *N*– cases.

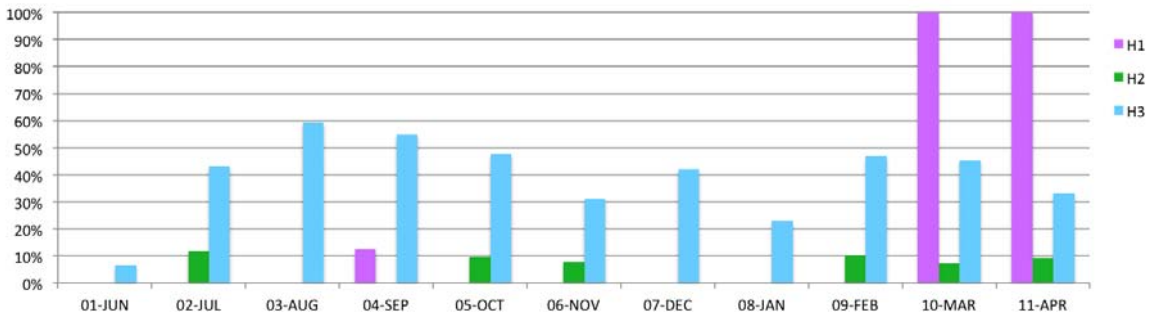

Figure 3. Temporal distributions of the proportion of missing navigations (*N0*) by hospital.

Despite we studied the intervention arm of a RCT, where OncoDoc2 should be used for all breast cancer decisions, there were 29.3% of missing navigations *N0* (163/557). If they correspond to situations where MDM participants actually did not use OncoDoc2 to decide, these cases may also be explained by technical problems (for some reasons, navigations were done but not recorded). Paradoxally, the compliance of MDM decisions when navigations were missing was quite high (90.2%), comparable to the compliance rate of *N+* decisions, and significantly higher than the compliance rate of *N–* decisions. Missing data is a ubiquitous problem in all studies of medical research and inadequate handling of missing data can have a detrimental impact on the data analysis.[22,23] Knowing the mechanism is useful in identifying the most appropriate analysis. However, the missingness mechanism is often unknown and methods for dealing with missing data such as complete case analysis (excluding patients with missing data), mean substitution (replacing missing values of a variable with the average of known values for that variable), and last observation carried forward are commonly used for analysis. Missing data is also often considered to be indicative of participant relapse, and under that assumption, many researchers have relied on setting all missing values to the worst-case scenario for the outcome. This sort of single-imputation method has been criticized for producing biased results. More recently, methods involving multiple imputation approaches have been developed.[24] In our case, H_3 hospital who is also the hospital with the highest rate of patient accrual, had 41.9% (138/329) of missing navigations. These cases may correspond to complex patient cases (bilateral breast cancer or cancer relapse) that MDM participants might have considered to be outside the scope of CPGs, thus not handled by OncoDoc2, and to be discussed on a case by case basis (no need to use the system). Other explanations such as a seasonal effect (more *N0* for H_3 in summer holydays period), or resident schedules, could be given. Concerning H_1 hospital, nearly all *N0* decisions occured in the last two months where the MDM secretary was on sick leave.

Although navigating OncoDoc2 was developed on the principle of a check-list of patient criteria easy to document, and actually necessary for the decision-making process, there was at least one error in 52% of the navigations. Most patient criteria were concerned, whether they were often ("Unique invasive tumor") or rarely ("T4 tumor") used, and quantitative ("Invasive tumor size [pre-surgery]") or qualitative ("Contraindication to lumpectomy"). When using OncoDoc2, the selection of the answer is made by simply clicking on the right value. Since the different values are displayed the some below the others, "juxtaposition errors" may explain some wrong answers. A second hypothesis could be that discordant data are not entry errors but clinical errors. Beyond clinicians' knowledge of CPGs, HIT could reveal the discordance between patient actual information and clinicians' belief of what this information is. Finally, since CRAs used the information recorded in medical records to navigate OncoDoc2, we should also consider that navigation errors correspond to errors of the medical record, corrected on the fly during the MDM navigation, but not revised in the medical record. Another interesting point is the discovery of the compliance rates of 90.1% and 65.5% in $Recos+$, resp. $Recos-$, situations of *N–* navigations. In $Recos-$ situations, MDM physicians made an incorrect navigation and got "wrong", inappropriate, recommendations, but decided to follow them. This can be interpreted as an overtrust in technology (similar to the Type 9 of UACs decribed by Campbell et al.[4], called overdependence on the technology).

This study has some limitations including the small size of the samples of both MDM decisions and hospitals, the

use of a specific CDSS OncoDoc2 including a user-controlled navigation to instantiate patient parameters, and the application to a single pathology (breast cancer management). With respect to *N–* navigations, errors resulted from the manual entry of data, since no full clinical EHR system was available in the hospitals. We don't know whether there would have been less errors if part of the data needed for OncoDoc2 navigations had come from an EHR. This is an important question and a stake for the development of EHRs and surrounding HIT tools. This however reinforces the importance of initial data entry quality into the health care digital environment. Moreover, we considered reference navigations as the gold standard and then "error-free". Thus, only non-compliant decisions were checked to assess the quality of data entry. However, there also could be errors in navigations considered to be compliant. By only evaluating one direction of errors, there is small risk of bias in the results, with a under-estimation of the error rate in compliant MDM decisions. Finally, since H_3 had a large majority of *N0* decisions (84.6%), the compliance difference could also be explained by the hospital.

We observed that the compliance rate of MDM decisions was significantly lower for *N–* navigations (80.0%), than for *N0* and *N+*, with a rate as low as 65.5% in $Recos-$ situations. Surprisingly, the compliance rate of MDM decisions with missing navigations *N0*, where we assumed that the CDSS was not used, was comparable to the one measured for correct navigations *N+*. Moreover, it was higher than the compliance rate published for breast cancer management.[11,10] This raises questions related to the context of non-using the system. Not using the CDSS for certain patient cases, whereas it is used otherwise on a regular basis, seems to be not prejudicial to decision quality. This might stem from a positive contamination effect. Then, from what was observed, it seems that it's better not to use OncoDoc2 than to use it improperly. Though not demonstrated here, similar effects might occur with other CDSSs or HIT tools, which emphasizes the importance of the correct use of HIT tools. This explains why numerous research teams are currently investigating the broad range of human factors in user-CDSS interactions. This raises the issue of usability[25] and enlightens the importance of better system development, testing, implementation, and end user training to promote the good use of HIT tools, like CDSSs, to actually benefit from HIT potential to enhance the quality and safety of health care. In this way, we could avoid the next decade to be a "dangerous decade".[1]

Acknowledgments

Authors thank URC-EST for its logistic support, AP-HP for providing the OncoDoc2 system, clinical research assistants for collecting data, all MDM members who participated to the study, and Prof. S. Uzan for his support in promoting this study.

Impacts of EHR Certification and Meaningful Use Implementation on an Integrated Delivery Network

Watson A. Bowes, III, MD, MS Intermountain Healthcare and Department of Biomedical Informatics, University of Utah, Salt Lake City, UT

Abstract

Three years ago Intermountain Healthcare made the decision to participate in the Medicare and Medicaid Electronic Heath Record (EHR) Incentive Program which required that hospitals and providers use a certified EHR in a meaningful way. At that time, the barriers to enhance our home grown system, and change clinician workflows were numerous and large. This paper describes the time and effort required to enhance our legacy systems in order to pass certification, including filling 47 gaps in (EHR) functionality. We also describe the processes and resources that resulted in successful changes to many clinical workflows required by clinicians to meet meaningful use requirements. In 2011 we set meaningful use targets of 75% of employed physicians and 75% of our hospitals to meet Stage 1 of meaningful use by 2013. By the end of 2013, 87% of 696 employed eligible professionals and 100% of 22 Intermountain hospitals had successfully attested for Stage 1. This paper describes documented and perceived costs to Intermountain including time, effort, resources, postponement of other projects, as well as documented and perceived benefits of attainment of meaningful use.

Introduction

In the U.S. over 89% of 5011 eligible hospitals and over 66% of 527,200 eligible professionals have received an incentive payment from the Medicare and Medicaid EHR Incentive Program, which stems from the Health Information Technology for Economic and Clinical Health Act (HITECH), and American Recovery and Reinvestment Act (ARRA) of 2009.[1] Over 20 Billion dollars of incentives have been distributed for healthcare information technology (HIT) projects to accelerate the adoption of EHRs and other technology, and to have the technology used in a meaningful way[2]. Intermountain Healthcare eligible hospitals (EH) and eligible professionals (EP) were eligible for approximately $35 million in incentives from Medicare and Medicaid for the first year of Stage 1 of the incentive program in 2013. $28M was estimated for our hospitals and $5M for our ambulatory providers.

A paper presented at the AMIA proceedings in 2011 described the decision to move forward with meaningful use and outlined the gaps and challenges that faced Intermountain Healthcare for this endeavor.[3] Because our EHR at Intermountain was self-developed, we had to certify our EHR prior to meeting meaningful use to meet the requirements outlined in the EHR Standards rule[3] and related National Institute of Standards and Testing (NIST) Approved Test Procedures for certification.[4] We identified 20 functionalities that needed no modification, but 47 requirements which required some enhancement or completely new development in order to pass certification. See Table 1.

Table 1. EHR Functional Gaps - 2011

Care Site	Modular System	Functionality Category	Later Removed
Ambulatory	HELP2	Automate measure calculation (ambulatory)	
Ambulatory	HELP2	Electronic prescribing

Hospital	HELP2	Patient-specific education resources	
Hospital	HIE	Electronic copy of discharge instructions	
Hospital	HIE	Electronic copy of health information	
Hospital	HIE	Electronic copy of health info (d/c summary)	
Hospital	HIE	Exchange clinical info summary record	

We also reviewed the CMS Incentive Program Rule[5] to understand the Stage 1 requirements necessary to meet meaningful use in the ambulatory and hospital settings. Our workflow analysis identified 10 meaningful use workflows that we projected would require change to clinician workflow to bring all of our hospitals and ambulatory providers above the required thresholds. These workflows were identified as Problem List (hospital and ambulatory), Medication Allergy List (hospital and ambulatory), Computer Provider Order Entry (CPOE List hospital and ambulatory), Smoking Status List (hospital and ambulatory) , Patient Education List (hospital and ambulatory), Electronic Prescribing (ambulatory only), and Timely Access to Health Information (ambulatory only). See Table 2.

Table 2. Meaningful Use Status 2011 – Workflow Challenges

Final Meaningful Use Stage 1 Objectives	Measure Requirement Threshold	Percent of Providers that Meet Measure	Number of Hospitals that Meet Measure out of 22
Use Computerized Provider Order Entry (CPOE)	30%	55%	18
Electronic Prescribing [EP only]	40%	5%	N/A
Problem List	80%	20%	None

Final Meaningful Use Stage 1 Objectives	Measure Requirement Threshold	Percent of Providers that Meet Measure	Number of Hospitals that Meet Measure out of 22
Medication Allergy List	80%	45%	5
Smoking Status	50%	20%	19
Timely Electronic Access to Health Information [EP Only]	10%	20%	N/A
Patient Specific Education	10%	50%	None

Our 2011 analysis demonstrated that we had significant work to do to close the EHR functional gaps and the meaningful use gaps. We divided the work into three major projects; EHR certification, led by our Information Systems (IS) division, hospital meaningful use implementation, and ambulatory meaningful use implementation. Intermountain made reaching meaningful use a board goal for our system, giving the project top 3 status in our list of enterprise projects. This decision by leadership allowed all three project teams to obtain the staffing and clout to mobilize to meet the challenge. Projects prioritized lower were postponed to allow for the meaningful use project to move forward. Likewise, the Intermountain Medical Group of ambulatory physicians and the 22 hospitals prioritized meaningful use highly, making it a board-level goal for their organizations.

Methods

This analysis was performed at Intermountain Healthcare, a not-for-profit integrated health care delivery network which operates 22 hospitals (130,000 admissions per year), employs over 900 physicians working in 170 ambulatory clinics. Intermountain's clinical information systems have been described previously.[7,8] We currently use two home-grown, legacy clinical information systems, HELP in the hospitals and HELP2 primarily in the ambulatory setting. Over 13,500 unique users access HELP to retrieve results and/or document care for over 123,000 patient records per month. Over 13,000 clinicians use the HELP2 EHR each month to access records or document care on over 260,000 unique patients. Providers access different modules for different functionality, including documentation of progress notes, problem lists, medication orders, nursing documentation, etc.

Developing EHR Functionality for Certification

We assembled twelve teams and divided all of the Stage 1 EHR NIST requirements that required enhancement or creation among the teams. These functions are shown in Table 1. Each team consisted of a team lead analyst, programmer, informaticist, terminology analyst, quality assurance analyst, certification analyst and often an interface analyst. These teams reported to a project manager, and certification lead. The project was prioritized at number 1 or 2 in IS during 2012 and 2013

Achieving Meaningful Use

Intermountain formed the Meaningful Use Steering Committee (MUSC) to oversee the goal of attaining meaningful use in our Intermountain Medical Group (IMG) of employed physicians and in our 22 hospitals. This committee included VP level physician and nursing executives, certification lead, project manager, informaticist, MU Initiatives Manager, and regulatory advisor from the IMG and hospital system. The team met weekly and could escalate urgent issues to the Chief Information Officer, Chief Medical Officer, and Chief Nursing Officer for assistance in prioritization for resolution. Each Hospital and IMG regional champion formed Meaningful Use working groups that were responsible for setting and tracking meaningful use goals. These working groups consisted of regional physician and nurse champions, regional nursing consultants, and clinical systems specialists to train on and track meaningful use goals. Meaningful Use metric dashboards with drill-down capability were created for hospitals and IMG regions and clinics and were monitored for progress and/or issues by the MUSC.

Hospital working group tasks included education of the hospital leadership about meaningful use, assembling local teams representing nursing, physicians, information systems, finance, regulatory compliance, and health information management - medical records (HIM). These teams met to review requirements and reinforce or establish workflows to meet the meaningful use targets. Departments with deficiencies in particular areas, such as Problem List or CPOE were encouraged to adopt successful workflows that were in place in other Intermountain locations. Expectations were set by local leadership to stress the importance of compliance with the meaningful use measures.

The IMG ambulatory physicians working groups worked with clinical systems specialists and clinic managers to identify workflow deficiencies, then to modify and improve these workflows. Yearly provider incentives (15% of base pay) were based partially on whether a provider reached meaningful use.

Objective Impacts

All information system team members tracked their time for function development and certification-related tasks in project management software. This time tracking data as well as resource hourly rate was stored in our enterprise data warehouse (EDW) and converted to a data cube for analysis in order to determine time and dollar cost for the EHR certification project. Work-in-progress (WIP) Actual amount in dollars is defined as the WIP times an FTE rate, which is a normalized FTE rate by role. Ambulatory and hospital meaningful use team leads estimated time and effort project tasks by resource group to achieve meaningful use. Hourly rate for meaningful use project team roles was derived from an average of rate by role taken from Intermountain human resources records.

Workflow changes were tracked by following changes in meaningful use automated measure metric values, e.g. percent of a hospital's patients that had a coded problem on their problem list. These metrics, along with clinical quality measure (CQM) measures were generated weekly for all providers and hospitals and stored in our EDW. Total dollar incentive payments received for successful attestation for all providers and hospitals from Medicare and Medicaid were tabulated.

Subjective Impacts

Subjective impacts of the EHR certification and Meaningful Use project, both negative and positive, were elicited from information system, hospital, and physician executive leadership. Clinical leadership was asked about the financial and reputational impact as well as impact on patients, physicians/nurses and ancillary staff. Information systems product managers were asked whether the EHR certification and Meaningful Use project had important impacts such as promotion or demotion of other projects.

Results

Objective Impacts

The total hours and estimated costs to achieve Stage 1 EHR certification for outpatient and inpatient systems are shown in Table 3. Total hours were 221,765 between 2011 and 2013 and estimated costs came to $12.2M.

Table 3. EHR Certification Expenditures

	2011		2012		2013		2011-2013	
IS Systems	WIP Actual HRS	WIP Actual AMT	WIP Actual HRS	WIP Actual AMT	WIP Actual HRS	WIP Actual AMT	Total WIP Actual HRS	Total WIP Actual AMT
CPOE	6,671	$ 389,345	29,904	$ 1,715,264	34,189	$ 2,022,520	70,762	$ 4,127,129

Sanpete (CAH)	$ 150,000	PENDING		$ 571,700	28-Feb
Cassia (CAH)	$ -			$ 459,141	31-Dec
Delta (CAH)	$ -			$ 446,000	PENDING
PCMC	$ -			$ 2,094,000	PENDING
received	$ 17,262,742		received	$ 2,227,758	
pending	$ 345,000		pending	$ 9,293,000	

For Stage 1, through 2013 EP (year 1 and year 2) and EH (year 1) received and pending incentives totaled $46.3M. Total costs for EHR certification and meaningful use implementation and attestation were $17.3M.

We identified certain meaningful use clinician workflows we anticipated would be challenging. Meaningful Use could only be achieved by an EP or hospital if all measures were met. These challenging workflows, with before and after results, are shown in Table 8. For instance, only 55% of EPs met the CPOE measure at the beginning of Stage 1. By the end of Stage 1 attestation period, 100% of providers met the CPOE measure.

Table 8 Workflow Challenge Results, Before and After Stage 1 Implementation

Meaningful Use Stage 1 Objectives	Measure Requirement Threshold	Percent of Providers that Met Measure BEFORE	Percent of Providers that Met Measure AFTER	Number of Hospitals that Meet Measure out of 22 BEFORE	Number of Hospitals that Meet Measure out of 22 AFTER
Use Computerized Provider Order Entry (CPOE)	30%	55%	100%	18	22
Electronic Prescribing [EP only]	40%	5%	94%	N/A	N/A
Problem List	80%	20%	84%	None	22
Medication Allergy List	80%	45%	94%	5	22

Meaningful Use Stage 1 Objectives	Measure Requirement Threshold	Percent of Providers that Met Measure BEFORE	Percent of Providers that Met Measure AFTER	Number of Hospitals that Meet Measure out of 22 BEFORE	Number of Hospitals that Meet Measure out of 22 AFTER
Smoking Status	50%	20%	99%	19	22
Timely Electronic Access to Health Info [EP Only]	10%	20%	85%	N/A	N/A
Patient Specific Education	10%	50%	98%	None	22

Subjective Impacts

Information system leaders commented that some important projects were delayed by EHR certification and meaningful use. These included replacement of legacy system functionality in labor and delivery, electronic consent handling, Clinical Health Information Exchange workflow integration, Exchange Provider Directory, enterprise provider master replacement, and replacement/enhancement of inpatient CPOE functionality (vs emergency department CPOE, which was used for meaningful use). IS leadership did mention that some projects were accelerated due to the meaningful use project including CPOE in the Emergency Department, and E-prescribe functionality.

Clinical leadership from the IMG and hospitals both agreed that there was reputational benefit from achieving meaningful use. In addition, they agreed on the benefit of the incentives and potential avoidance of future penalties. IMG leadership felt that patient engagement was likely improved after meaningful use, and was neutral on patient safety and patient satisfaction. Hospital leadership was neutral on the question of patient engagement, patient safety, and patient satisfaction. Both hospital and IMG leadership had feedback that physician and nurse productivity was negatively impacted. The IMG and hospital leadership also felt that clinic and emergency department (ED) physician, ED and clinic nurse, and clinic ancillary staff satisfaction was negatively impacted, due to the extra work necessary to meet meaningful use.

Discussion

This evaluation covers two very large projects at our institution; EHR enhancement/certification and EHR implementation at clinics and hospitals in order to meet meaningful use. This is by no means a comprehensive summary and evaluation of these two projects. However, we do describe with some objective and subjective information, some preliminary findings that inform the cost and benefit proposition for the EHR Incentive Program. The availability of detailed project information such as tasks, time, and resources for both the EHR enhancement/certification effort, and for the organizational work to meet meaningful use both in the outpatient and inpatient setting was very informative to us. We also tracked growth in EHR function usage, such as CPOE, E-prescribe, and Problem List throughout the clinics and hospitals as a result of the meaningful use requirements. Our study had several limitations. We did not track the impact/cost of the workflow changes to clinicians (such as time nor effort spent). Nor did we formally survey all the clinicians about workflow changes and satisfaction.

The decision to certify our EHR and meet meaningful use for Stage 1 use was a success from a strictly financial perspective. However, the true cost and benefit to the organization is not yet completely understood. We can see that the use of the EHR functions that are prescribed by meaningful use has grown. However, this is balanced with preliminary subjective feedback from clinicians that feel that patients may be more engaged, while these same clinicians are feeling less productive and less satisfied. Further analysis on the impact of the EHR incentive program is needed to shed light on this dilemma. Meanwhile, the Stage 2 requirements and workflows are looming.

Conclusion

This paper describes the experience and some preliminary impacts resulting from EHR certification, implementation, and successful attestation for meaningful Stage 1 at Intermountain Healthcare.

Abstract

Developing gross and fine motor skills and expressing complex emotion is critical for child development. We introduce "StorySense", an eBook-integrated mobile app prototype that can sense face and sound topologies and identify movement and expression to promote children's motor skills and emotional developmental. Currently, most interactive eBooks on mobile devices only leverage "low-motor" interaction (i.e. tapping or swiping). Our app senses a greater breath of motion (e.g. clapping, snapping, and face tracking), and dynamically alters the storyline according to physical responses in ways that encourage the performance of predetermined motor skills ideal for a child's gross and fine motor development. In addition, our app can capture changes in facial topology, which can later be mapped using the Facial Action Coding System (FACS) for later interpretation of emotion. StorySense expands the human computer interaction vocabulary for mobile devices. Potential clinical applications include child development, physical therapy, and autism.

Introduction

The importance of stories in physical and emotional development, and health practice, cannot be overstated. Stories are a universal concept across cultures that predate the written word. Stories have been told from prehistoric to contemporary to modern times. They also transcend multiple cultural barriers: Language, age, culture, and education. As a result, many stories are shared across cultures and/or are retold with differentiating degrees of variation and purpose. The earliest of storytelling was oral and heavily combined with gestures and expression to enhance the effectiveness of conveyance.[1] As a result, stories can also be a mechanism for physical development and have the ability to elicit emotional responses. Unfortunately, gesture and expression in storytelling has not translated to mobile technology (i.e. eBooks) to the same degree.

Computers and information technology are relatively new to the process of storytelling. Newer still are mobile devices. However, their growing ubiquity and advancing technology potentiate storytelling in new, dynamic, and undiscovered ways. Commonly, mobile devices rely on screen input interface and touch to simulate the standard functions of books. Swiping your finger from one side of the screen to the other performs page turning, and page leaves are animated to resemble real pages. Tapping and pinching are additional features offered by mobile devices. They allow zooming into pages for better views and selection of text to capture content for alternate uses.

Unfortunately, these actions do not meet the range of motion necessary for a child's comprehensive "motor skills" development. They also do not provide sensory and algorithmic identification methods for confirming that the young reader, or the child being read to, has actually performed the task. However, there are many unused mobile device sensors that, if leveraged, can: 1) enhance the way children use motor skills while experiencing eBooks, 2) confirm the execution of specific motor skills, and 3) provide a better understanding of the child's emotional experience during the course of their interactive eBook experience.

We identified several untapped mobile device sensor resources ideal for identifying motor development and assessing emotion during storytelling when using eBooks. We chose to focus on the two sensors that are least used, yet ubiquitously available on most mobile devices. The two sensors are the camera for image capturing and the microphone to capture sound. Advances in camera technologies more accurately simulate the capability of an eye where small and large ranges of motion can be captured, as well as objects detected and identified. Sound detection

is the most common feature of any mobile device, and is able to detect and differentiate greater ranges of sound than ever possible.

Given the knowledge gap related to mobile device assisted motor development and emotion detection, and the opportunities provided by new mobile technologies, we aimed to answer the question "Can an ebook-integrated high-fidelity mobile app prototype be developed for promoting child motor skills and taxonomically assessing children's emotional responses?" The purpose of this work was a proof-of-concept to develop "StorySense", an app that can promote child motor skills and identify emotion, for healthy child development. Our development goal included creation and testing of two sensory functions and identifying necessary programming and topology classification libraries. To evaluate our work we employed a system development life cycle stage-based evaluation model.

Theoretical base

The theoretical basis for this application's use in child development comes from the fundamentals of interactionist theories such as the neuronal group selection theory and the dynamic system theory.[2,3] These theories support that the infant's motor abilities emerge as a result of the child, task, and the environment with individual variability.[4] The plasticity of the brain in children is the neurophysiological basis for promoting motor skills in young children. Research over the past fifty years has confirmed that an infant's brain is built over time and that the development allows for future skills to emerge. Brains are modulated by genetics and experiences that will affect the outcome of the child.[5] StorySense provides interactive experiences similar to those that are known to have a modulation effect on the outcome of a child's gross and fine motor development.

Expression through facial action, gesticulation, and sound

Facial expressions are fundamental to the communication of simple and complex emotion. Movements in the muscles and skin, particularly around the mouth and eyebrows, provide a large visual vocabulary of meaning and emotional terminology.[6] Similarly, gesticulations with hands and the creation of sound (e.g. clapping, rubbing, banging, tapping, snapping) are intrinsically tied to communicating, and can add depth to conveying emotional information while children experience eBooks.[7]

There are two types of facial expressions that contribute to communication, voluntary expression and emotional expression.[8] Voluntary expression follow learned display rules in emotion and are made consciously (e.g. blowing a kiss). Emotional expression, on the other hand, is often displayed unconsciously. This includes facial expressions like distress, disgust, interest, anger, contempt, surprise, and fear. Despite the fact that individuals do not realize they are producing these expressions, this visual autonomic vocabulary is information rich and universally comprehendible.[6] Thus, the eyes and mouth are a fundamental identifier in facial recognition.

Sounds are also used for processes of identification. Sound variation and scale carry varied meaning (e.g. clapping, screaming, and whistling). It is an ideal indication of information that is both consciously and subconsciously conveyed by potential technology users. Both sound and facial movement reveal feelings and thoughts. However, the range and types of feelings and thoughts can be very different and very unique to one mode of information conveyance versus the other. While facial movement can indicate things like attraction, disgust, uncertainty, sound on the other hand can indicate specific emotions through utterances, speech, and various onomatopoeia (e.g. hissing).[7] StorySense both leverages and builds on previous research in: face, motion, and sound recognition; facial action coding and emotion identification; sensing for people-centric applications; and reaction sensing. Below, we discuss work relevant and contributory to this project.

Facial Action Coding System (FACS)

The systematic categorization of facial movements to identify expression of emotion is a historic practice of psychologists. In 1978 Paul Ekman and W.V. Friesen developed a Facial Action Coding System (FACS) by analyzing changes in facial appearance created during various combinations of facial muscular contraction. Their goal was to develop a reliable scoring metric by which human raters can identify facial behaviors. The result was FACS a taxonomic system of human facial movements that can help raters code changes in elements of the face (i.e. eyes, mouth) and their muscular movements.[9]

Today, FACS is the most widely used descriptive measurement tool for facial behaviors, and aids computers to topologically detect faces and their geometry. It also allows for the reduction of subjectivity and the use of high-throughput computational methods. FACS measurement units are Action Units.[9] Consequently, FACS scores do not provide meaning of facial behavior, and can only be used descriptively. To address the need for meaningful interpretation of FACS scores, researchers developed the Facial Action Coding System Affect Interpretation Dictionary (FACSAID). FACSAID links facial expressions with their psychological interpretations and models them to facial behaviors, then stores this information in to a relational database.[10] Thus, the raw FACS scores potentially produced by a StorySense scan can be translated into more psychologically meaningful concepts. By leveraging both the FACS taxonomy and FACSAID as knowledge bases, the final version of StorySense will be able to produce emotional profiles of a reader's facial movement for clinical interpretation and possible therapeutic use.

Sensing for people-centered mobile applications

There have been many applications of sensing technology for people-centered mobile applications. Cameras are one of the most utilized features in mobile devices and have some of the most varied function. Originally the camera's function was solely relegated to pixilated single pictures. Now we find high resolution images that can be instantly manipulated, as well as motion cinematography.[11] Similarly, the microphone has advanced beyond the standard receiver and plays a larger role in capturing sound. It pairs with camera recordings to produce video recordings, takes dictation, and is used to input commands.[12] As previously mentioned accelerometers are at the forefront of much of the motion detection capabilities of mobile devices.[13] What's more, when paired with GPS systems and the gyroscope, the duo maximize the devices ability to orient itself in the universe.[12–14] Though this information can also be helpful in detecting the movement of the user, the combination of accelerometers and GPS are most often an indicator of distance traveled. The amount of distance traveled from one physical location to another is likely to be short and of less relevance during a child's experiencing while reading an eBook. Thus, we did not focus on these to available features.

Reaction sensing

A developing area in HCI is reaction sensing. Reaction sensing goes beyond the normal bounds of input and imputation. Researchers and developers are leveraging sounds and their variations in order to enhance HCI and create a multifaceted user experience.[15] Moreover, advanced reaction sensing leverages the behavioral cues that are autonomic to people.[15,16] In this way the interaction more easily mimics what a person would expect another person to react to. For instance, previous work in sound recognition includes scalable sound sensing for people-centric applications on mobile phones (i.e. SoundSense).[15] Work in face detection includes technologies such as blink detection for real-time eye tracking.[16]

Moreover, advances such as natural language processing (NLP), machine learning, and data mining, can combine with multimodal sensing technologies, and allow mobile devices to anticipate user needs and react organically to people's naturally occurring behavioral cues.[16–18] This has the added benefit of being able to track and log new and existing movements and reactions. As a result, the potential to increase the known vocabulary of reactions to stimuli means we can process, analyze, and understand behavioral cues collectively and longitudinally, making high-throughput analyses a real possibility.

Methods

We built StorySense in Java for Android. We successfully tested and ran our applications on a Nexus 7 tablet and Samsung Galaxy S III mobile phone. We focused on two areas of sensing, sensing sound produced by high motility (clapping) and low motility (snapping) processes, as well as detecting facial changes, with a focus on eye movement. We also systematically identified classic children's stories that were ideal for incorporating movement and promoting motor skills.

Criterion and methods for choosing a story for the prototype

We defined story criteria to optimize our application's user experience, diversify options for interaction, and integrate fluidly with new sensing techniques. Our criteria included: English availability, multiple translations (for universality), internationally stable storyline, high graphic artwork, abstract storyline, availability/expired copy write, and animation potential. Using the Google search engine and leveraging its "Scholars" database, we performed a library literature search of thousands of choices. Based on our criteria we narrowed our results down to three possible stories: Peter Pan, Cinderella, and The Wizard of Oz. All researchers reviewed the final three stories. Ultimately, we chose Peter Pan because, of the three story options, it had the best balance of being well known and a stable storyline across cultures. The stable storyline across cultures was the penultimate criteria because it is an ideal trait for future evaluation.

In addition to identifying an optimal story for the prototype, we also had to edit the features of the story and create additional interactive illustrations and communicate functionality (Figure 1).

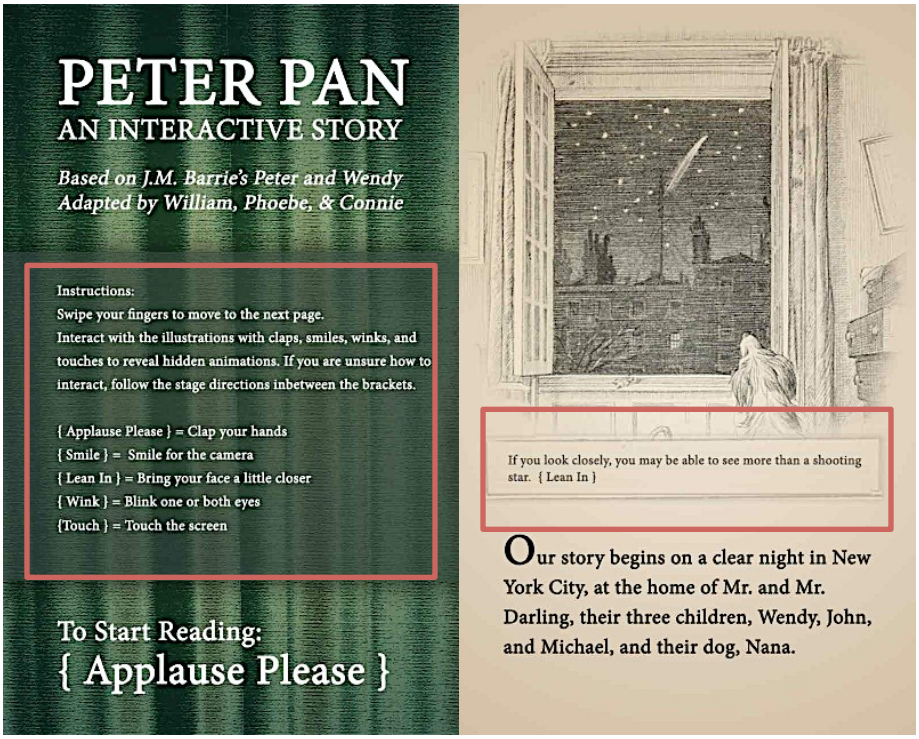

Figure 1. Modified illustrations (outlined in red).

Sensing sound: Clap/snap detection

For the purposes of prototyping, we chose to focus on clap and snap detection. We plan to explore detecting a wider range of sounds in the future. In consideration of the broad range of stories available as eBooks, it would be useful to detect and respond to a wider range of human sounds, such as sneezes, laughs, and snorts. However, sounds such as those we just listed are not produced using high-motility actions. Future noises that could be explored beyond clapping that are produced through high-motility actions include stomping and banging. However, we were unable to find these sound types to be useful in the same story. Originally we focused only on clap detection, however we needed a low-motility sound and verbalization (i.e. talking) for performance juxtaposition and sound identification. Thus, we quickly incorporated snap detection as well. This serves two purposes. In conditions where clapping is the preferred action; we want to make sure that sounds can be distinguished from similar sound patterns. This way the eBook can ensure that the desired physical activity is being performed. Secondly, we want to accommodate users who prefer to hold a mobile device with one hand and use snap detection. Furthermore, a story may elicit these sounds from its audience and perform a pre-designated response or action in return, or just respond to organically produced sounds as they happen naturally.

Sensing the face: Eye detection

We use facial recognition to detect and track user eye movement. Triggered by a user click, our application accesses the mobile device's camera and initiates a series of actions for facial recognition and eye tracking (Figure 2). In the development of the face recognition portion of the application, several decisions were made in regards to how we access a device's camera and how a user would be interacting with our application. First, we found there to be two different ways to capture images using the camera on Android. One is using an intent, which is using an existing camera application to take the photo. Second, is to create a custom camera application to take the photo. The first option would have another application come into the foreground, thereby occluding the story page and disrupting story flow. Thus, we chose the second option.

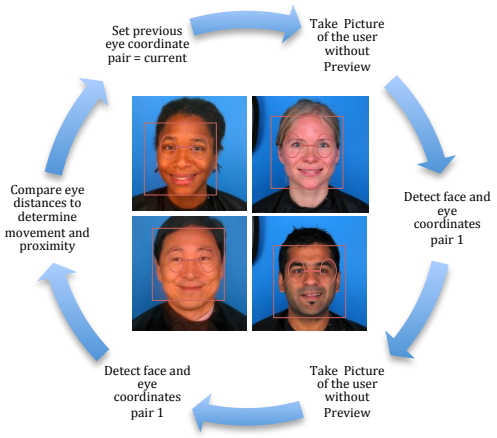

Figure 2. Face and eye detection. (Images from PICS database[19])

However, the second option had the Android required condition where in order to take a picture, there has to be a preview surface, meaning the user has to see what they are taking a picture of and then click to take a picture. The problem here is that we did not want a preview since it would occlude much of the story page as well as disrupt story flow. Ultimately, in order to get around this issue, we created a surface view and resized it to a single pixel on the screen, thus there is a preview, but it is not visible.

Evaluation

Development and evaluation of StorySense followed the systems development life cycle (SDLC), also referred to as the application development life-cycle, we have completed the preliminary analysis, systems analysis, requirements definition, systems design, development phases, integration and testing phase.[20] This evaluation highlights our experience and knowledge gained in the integration and testing phase. The following evaluation results are based on StorySense's current SDLC stage, benchmark lab testing.

Benchmark lab evaluation of system sensors

To evaluate StorySense's ability to detect and distinguish sound topology (i.e. talking, clapping, snapping) we used threshold detection. We looked at amplitude readings from mobile device and laptop microphones for a variety of sounds to determine a threshold. We observed amplitudes for: clapping slow and fast; clapping close and far; clapping slow and fast while talking; snapping; talking; yelling; and tapping the device. We ran these tests with two users, one who snaps loudly and one who snaps quietly. These performance tests were done while watching an amplitude meter to help us understand the basic differences in the amplitude over time. We recorded our results in the system and mapped clapping topologies to event triggers in the story.

We evaluated StorySense's ability to detect eye topology using visual tracking confirmation methods. The series of actions following the user click included capturing the user's photo using the front facing camera without a preview, thereby not disturbing or occluding the story page. The picture taken is then sent to a built-in face detector, and if a face is detected, the eye position is recorded. With the eye screen coordinates in-hand, a Peter Pan character image is drawn on the story page screen where the eyes were detected (Figure 3). That is, once we have one pair of eye coordinates; our camera module is able to take another user photo and extract the eye coordinates from that. If at least two pairs of eye coordinates are available, the application draws a Peter Pan character image at both eye locations and a dashed line between them to show the user's eye movement was tracked. This Peter Pan image allowed us to detect changes in eye topology, and was used in the prototype model for verification of metrics, direction, and actions performed.

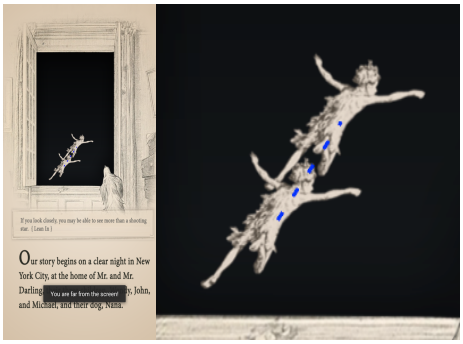

Figure 3. Eye tracking/Peter Pan indicators.

Furthermore, we conducted a performance evaluation of StorySense's face detection software, which consisted of testing if the application is able to detect faces (including recording the time used for detection in milliseconds [converted to seconds], and the resulting confidence factor) for a subset of 40 images from the Psychological Image Collection at Stirling (PICS) University database.[19] The image set from PICS included both ethnic and phenotypic diversity, and consisted of 22 male and 18 female images. The confidence factor used to gauge face detection is a property of the Android Software Development Kit's (SDK) "FaceDetector." This property is also known as the "Face Class", which holds information regarding the identification of a face in a bitmap. The confidence factor returns a value between 0 and 1, and it indicates how certain what has been found is actually a face.

Results

Sound detection evaluation results

The graphs below show that claps and snaps have significantly higher amplitudes than "indoor voice" talking at close range (~ a foot and a half away) (Figure 4). Another difference is that the claps and snap amplitudes go back down to zero very quickly, while talking has more of a zigzagged amplitude corona arch. Both of these features can be combined to yield reasonable results for clap and snap detection. While currently StorySense identifies anything above a threshold as a clap or a snap, it could benefit from further analyzing the sound following the initial trigger to determine if the sound is staying high or going back down quickly. This added feature would dramatically increase the ability of StorySense to detect claps and snaps.

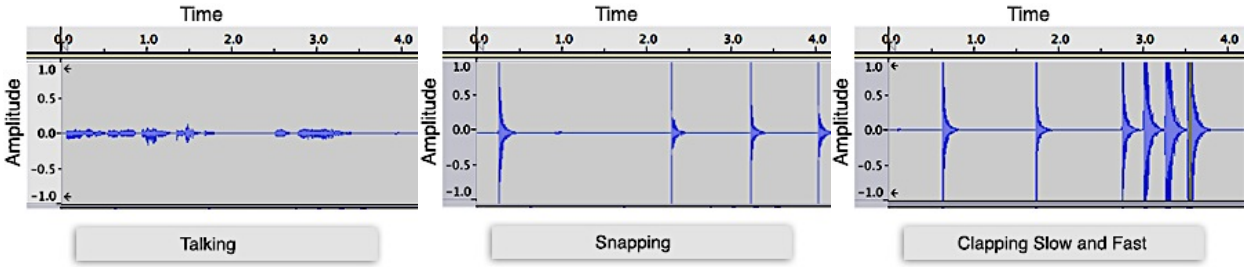

Figure 4. Sound types and amplitudes.

Unfortunately, the threshold we chose to use as our base level made it difficult to distinguish additional sounds such as snaps or short bursts from claps. If someone yells loudly or a nearby dog barks, the sounds will be registered as a clap and the system will respond accordingly. In general, people usually talk with "indoor voices" that stay below the threshold or read silently. More formal user testing could help to define the accuracy of this approach.

Face detection evaluation results

We were able to successfully procure eye coordinates; we also obtained the distance between the eyes. We were then able to use this information to determine additional changes in facial topology as well as the distance of the user from the screen. We could accurately calculate distance of user using eye size. The larger the eye was, the closer the user's face was to the screen. We could also use these variations in distance and eye size to detect eye blinking, proximity, and various movement types. Alternatively, if the user was too close (i.e. distance is greater than mobile device screen size threshold), then a warning successfully triggered and posted to the screen, telling the user to increase their distance from the face of the mobile device. This would remind users not to put their faces too close to the screen; thus, maintaining a safe viewing distance, as well as facial detection accuracy.

According to the Android application program interface (API) documentation, a confidence factor above 0.3 indicates good face detection. Our results from our face detection performance evaluation (Table 1) show that we have a 100% face detection (FD) rate, with average detection time being 2772 milliseconds (or 2.772 seconds) and average confidence factor being 0.522917008.

Table 1. Face detection performance evaluation (Time for face detection (FD) was converted from the original output in milliseconds to seconds).

Images were taken from the Psychological Image Collection at Stirling (PICS) University database: Category = 2D Face Sets (http://pics.psych.stir.ac.uk/2D_face_sets.htm); Set Name = Utrecht ECVP; Set Description = 131 images, 49 men, 20 women, collected at the European Conference on Visual Perception in Utrecht, 2008. Some more to come, and 3d versions of these images in preparation; Resolution = 900x1200 color.

Once eye movement and distance have been detected and calculated this data can be used to decompose the movement into specific AUs and extrapolated to produce a FACS score. Further, duration, intensity, and asymmetry can improve the accuracy of the score and its related FACSAID interpretation. Although we were currently only tested two uses of eye movement detection, the tracking capability provides possibilities for detecting and identifying other changes in face topology.

Discussion

The stage of our project is proof-of-concept. Our app currently detects discrete interactions, and contains system parameters to detect faces and sound with limited variation for both. Only a sample of the story is being used. System statistics indicate we have reason for concern that there will be device memory space issues when the full story is developed and running; thus, we have focused much of our subsequent work around optimizing the framework to ensure that it handles the loading of pages and animations more efficiently.

Better classifiers to differentiate between sets of sounds and images are highly necessary. Further, development of a larger sound and visual vocabulary and repository are additional goals for the prototype. We may be able to create a

foundational list of desired motor functions from our user survey and Morae 3.3 assessment tool during our first user evaluation, and then compare this list to the existing motions that can be detected by other apps in the Google play store library. Lastly, an immediate goal is to use OpenCV to improve image processing and facial feature detection.

What we have learned in the developmental phase of our app prototype are some of the optimal methods and barriers to creating an app that can be used to detect physical activity of children during their reading of an eBook. We have also identified ways that such functionality can be incorporated directly with the story. In the story of "Peter Pan", the section that tells the reader to clap their hands to bring Tinkerbelle back to life is a clear example of stories moments that directly elicit physical action to produce a story outcome.

Potential clinical applications and target populations

There are no studies using these kinds of application to promote childhood development. It has been shown that early intervention programs that focus on promoting motor skills, preverbal skills, and stimulation of brain development are highly effective. These programs use a variety of techniques that involve multiple senses. The cumulative experience with early intervention programs has confirmed these methods are effective in promoting infant development.[21] StorySense encourages children's motor skills and provides impetus for a response. The functions of StorySense are ideal for increasing child motor skills, and understanding the child's experience even when the child's ability to orally communicate is un-developed.

Our application could potentially facilitate communication skills and social interaction, as well as sustain the child's attention. For children and adolescents with autistic spectrum disorder (ASD) presenting with limitations in conventional forms of verbal and non-verbal communication, this application could provide an alternative form of therapy. Dependent upon the results of our future user evaluation, we could explore the realm of our application as an ASD clinical therapy that could identify limitations and weaknesses in children, as well as strengths and potentials.[22] Furthermore, we could explore application effects on communicative behavior, language development, emotional responsiveness, attention span and behavioral control over a period of time. It may also be possible to put real-time user specific health or physical activity information directly in the eBook story line to help both parents that are reading to their children and children readers to learn how to manage their health.

Contribution to the field(s)

StorySense contributes to the fields of facial recognition, expression coding, and dynamic learning by following the FACS standard of classification protocols and adding to its lexical library. Continued development of StorySense facial recognition algorithms should be able to code nearly any anatomically produced facial expression. During the story telling process, and guided by FACS and FACSAID, StorySense will be able to topologically deconstruct the child's facial movements into specific Action Units, calculate a FACS score, and identify the expression's related emotion. The AUs are independent of variations in human interpretation; thus, higher order decision such as the recognition of basal emotions, can be processed. Subsequently, once a facial expression and its related emotion have been identified, related actions can be pre-programmed into the eBooks story environment. Thus, emotion can also have an impact on the story line in a way that can be designed to address distress, anger, or discomfort, as well as leveraged for therapeutic use.

Future work

Our future work will aim to include geo-location data to trigger a function or change in the story line that could promote walking or encourage other movement (e.g. landscape animations could match the reader's location). We will also improve our application experience by incorporating references to points of interest near the user's current location.

Other future work will incorporate newer technologies and mobile device capabilities. For instance, recent developments such as spritzing technologies (http://www.spritzinc.com/blog/) could provide a way to improve a user's reading skills, speed and focus. Additionally, motion-sensing capabilities of mobile devices could open up a whole new channel of facilitating physical development, conceptually similar to what the Wii Remote motion sensing technology for Wii Sports does.

We were unable to build in a response to other high-motility actions (such as stomping or waving) due to lack of classifiers. Thus, we hope to contribute more classifiers to the established lexicons. Future programming will continue to build off of the work done around reaction sensing.[15,16] Part of our work will also include the development of a facial expression-to-emotion library that is common to children during the process of reading, or is able to distinguish facial movements that are specific to the reading process that may be easily confused with expressing emotion. Additional future work may include train a user specific image set to provide better user recognition with each application use. Thus, future application development will look to implement a more seamless image capture and camera process. More standard functionality such as dictionaries, word pronouncers, bookmarks, and highlighting will also be added.

Future evaluation

Future evaluation will involve usability testing using a user-centered iterative design process, and Morae 3.3 a usability data collection tool to capture audio, video, on-screen activity, and keyboard/mouse/touch input so that we may identify use and error patterns and gain insight into the effectiveness and acceptability of the mobile app's design. NVivo will be used to analyze qualitative data to provide insight into areas for future development.

Limitations

In the development of our application, we had difficulties with sound classification. Loud ambient noises may register as constant clapping. Moreover, as we added animations and more images to test the framework, it became apparent that there were memory related performance issues. Additionally, though face movement can be detected, the app does not yet differentiate between open/close eyes or mouths, which hindered wink and smile detection. Again, we plan on developing classifiers that advances the built-in functions of the mobile device to ameliorate these issues. Also, our sound threshold for testing made it difficult to distinguish additional sounds such as snaps or short bursts from claps. Other loud sounds are at risk of being registered as a clap and the system will respond accordingly. Future iterations of the application might incorporate OpenCV (A library of programming functions mainly aimed at real-time computer vision, http://opencv.org/), open source data sets, and/or more advanced libraries to improve overall face and sound detection.

Using a set of captured 2D images versus actual users is a possible limitation to our evaluation. Moreover, we have thus far only tested StorySense on a Nexus 7 tablet and Samsung SGH-T999 Android 4.1.2 (API 16) (Galaxy S3) 1.9 Mega pixel camera, HD recording @30fps with Zero Shutter Lag, BSI. Newer phone models and other devices that are more widely used (e.g. Apple iPhone) would not be immediately supported. We look to remedy this by creating an iOS version and using emulators as well as acquiring additional mobile devices for testing.

Lastly, the FACS taxonomy is based off of analyzing adult facial movements. There may be unforeseen variations in adult facial recognition. Also, the FACSAID database is based off of FACS codes, which may present a similar problem when classifying child emotions using an emotion dictionary database based on analysis from adult populations.

Conclusion

We accomplished a significant amount of our interactive goals. In the development of this prototype we explored sound and facial expressions, which could potentially contribute to several universal knowledge bases for reaction sensing (i.e. FACS). StorySense leverages unconscious and conscious cues in every day communication. We found that by using mobile sensory technology (i.e. camera and microphone), and integrating common algorithms, it is possible to obtain rich user information. In this way, stories on mobile devices can not only be read by the user, but the mobile device can read the user's conscious or unconscious emotional expression and cues, and adjust the story for a more dynamic and user-centered experience. We also found that sensors used for dynamic and user-centered experiences can be leveraged to promote high-motility action, which would aid in the development of motor skills for young children or children with developmental challenges.

Making Audit Actionable: An Example Algorithm for Blood Pressure Management in Chronic Kidney Disease

Benjamin Brown, MB ChB, MSc[1,2], Richard Williams, BA[1,2], Matthew Sperrin, PhD[1,2], Timothy Frank, MD, FRCGP[1], John Ainsworth, BSc, MSc[1,2], Iain Buchan, MD, FACMI[1,2]

Abstract

Despite widespread use of clinical guidelines, actual care often falls short of ideal standards. Electronic health records (EHR) can be analyzed to provide information on how to improve care, but this is seldom done in sufficient detail to guide specific action. We developed an algorithm to provide practical, actionable information for care quality improvement using blood pressure (BP) management in chronic kidney disease (CKD) as an exemplar. We used UK clinical guidelines and EHR data from 440 patients in Salford (UK) to develop the algorithm. We then applied it to 532,409 individual patient records, identifying 11,097 CKD patients, 3,766 (34%) of which showed room for improvement in their care: either through medication optimization or better BP monitoring. Manual record reviews to evaluate accuracy indicated a positive-predictive value of 90%. Such algorithms could help improve the management of chronic conditions by providing the missing link between clinical audit and decision support.

Introduction

Best practice clinical guidelines are widely used in health systems around the world, however, observed quality of care often falls short of these standards.[1] The gap between ideal and actual care often results in additional morbidity, mortality and preventable hospital admissions, each with human and financial costs.

Chronic kidney disease (CKD) is a prime example. In CKD, both declining kidney function (measured by estimated glomerular filtration rate: eGFR) and increasing urinary albumin:creatinine ratio (ACR) independently increase cardiovascular mortality risk 2-4 fold.[2] Clinical guidelines therefore recommend strict blood pressure (BP) control to reduce this risk.[3–8] Nevertheless, studies invariably demonstrate just 13-66% of CKD patients in the US[9–13] and 35-60% in Europe[14–19] actually achieve controlled BP levels. Not meeting these standards has substantial adverse consequences given the high global prevalence of CKD, estimated at 8-16%.[20]

Data from electronic health records (EHRs) are abundant and ever increasing. They reflect the real-world care that patients receive and are often compared against clinical guidelines for the purposes of audit.[21] EHRs also often capture reasons *why* patients may not have achieved quality standards in the first place (e.g. patient choice or contra-indication to treatment) and practical steps as to *how* they might be achieved in future (e.g. how to optimize current management). This information is rarely exploited by existing informatics tools that perform audit and feedback – both in experimental studies and in routine practice.[11,14,24–28] Feeding such information back to practitioners has been shown in meta-analyses to produce greater improvements in patient outcomes than simple audit because it is more actionable by practitioners.[22,23] Therefore adding this functionality to audit and feedback interventions is likely to lead to greater improvements in patient care by connecting it with consequent quality improvement actions.

Aim of this study

The aim of this study was to develop and estimate the accuracy of an algorithm that searches EHR data to feed back practical, actionable information to clinicians regarding how they could improve care for patients in accordance with clinical guidelines. We used the example of BP management in CKD to test the feasibility of this method.

Importance and relevance of this study

This algorithm could provide the missing link between clinical audit and decision support, thus reducing the latency between clinical quality information and actions to improve care. Focusing on CKD and BP management, the algorithm developed here can be applied directly to EHR data to help reduce adverse cardiovascular outcomes. The approach in general can also be abstracted to other chronic conditions where physiological parameters reflect, at least in part, the quality of care provided to patients (e.g. cholesterol in cardiovascular disease; glycated hemoglobin in diabetes).

Methods

Algorithm development

We used anonymized EHR data from the City of Salford (population 234k) in the UK to develop the algorithm. Since the early 1990s, most UK citizen's primary healthcare records have been stored as machine-readable clinical codes (mainly Read codes v2 and CTV3). Over 300k different entries exist, covering care-processes, diagnoses and medications.[29] Practitioners can enter narrative free-text to supplement certain Read codes, though it is the codes themselves that are used for official purposes in the UK National Health Service (NHS) such as provider payment, public health programmes, health service planning, population health data, clinical performance assessment, and research.[30] Read code collections therefore provide important insights into the UK population's health.

We extracted alphanumeric codes and associated rubrics from a central database of all patients that received care in Salford from 2001-2012. These were then transferred securely to The University of Manchester as text-based vector files for analysis in Microsoft SQL Server 2008. The Salford database has collated EHR data daily from 53 primary care providers and one secondary care provider since 2001. We designed the algorithm to make inferences about how to improve BP management for CKD patients using coded EHR data in the following sequence: 1) identify patients with CKD; 2) identify those from Step 1 in whom it was appropriate to pursue quality standards for BP management; 3) identify those from Step 2 who did not achieve the quality standards; 4) provide information on what action could be taken to enable patients from Step 3 to achieve the quality standards.

In accordance with accepted methodology,[31] we developed and tested the algorithm iteratively. Initial algorithms were written as narrative based on clinical guidelines and authors' (BB and TF) clinical knowledge. The narrative was then translated into machine readable form using existing codes within the EHR dataset and dictionaries of Read codes used for primary care performance related pay.[32] To optimize the performance of the algorithm, we calibrated it with manual clinician review. Two clinicians (BB and TF) manually reviewed the coded data of randomly selected anonymized EHRs of patients receiving care in Salford between 2010 and 2012. For each of the 4 steps in the algorithm sequence, batches of 20 records were reviewed (10 identified positive and 10 identified negative). Based on these findings, the algorithm programming logic was modified as necessary. When additional codes were added to the algorithm, synonyms were identified within the full dataset (2001-2012) and also included. Further reviews of records were undertaken until the algorithm correctly identified all patients in the batch.

Algorithm accuracy study

Participants: We applied the final algorithm to the whole Salford EHR dataset (2001-2012) to make inferences about how to improve the quality of CKD BP management in Salford between 2011 and 2012.

Test methods: To test the performance of the algorithm, we randomly selected patient records it identified that had not been used in the development phase to calculate the positive predictive value (PPV). We chose to use PPV for: 1) clinical importance – in its real-world application, each patient identified by the algorithm will require further action by a clinician, so achieving a high PPV is essential to prevent over-burdening practitioners; and 2) pragmatism – to adequately assess specificity and sensitivity would require the manual review of thousands of records for each stage in the algorithm sequence, for which resources were not available. We defined the PPV as the number of patients identified by the algorithm where the clinicians (BB and TF) deemed they had CKD and that steps could be taken to improve the management of their BP, divided by the total number of records identified by the algorithm. For each patient tested, both BB and TF independently reviewed the anonymized coded data from their EHR and made a clinical judgment in accordance with national UK CKD clinical guidelines.[4] Any disagreements were resolved through discussion.

Statistical methods: We used a worst-case scenario of a predicted 50% PPV to determine the necessary sample size to test the algorithm (though we anticipated the algorithm would perform much better). We calculated that to detect a PPV of 50+/-10% with a two-sided α of 0.05, a minimum sample size of 96 patient records were required. We undertook reviews of 100 records to account for the imperfect nature of the review process. Statistical analysis was performed in R.[33]

Results

Algorithm development

In total, we manually reviewed 440 different patient records over 22 iterative cycles during the development process. Between 2001 and 2012, we found over 165 million individual codes in the Salford data, of which 151

million (92%) were Read code v2 and 14 million (8%) were codes specific to commercial EHR information systems. Most codes (133 million, 81%) originated in primary care and 32 million (19%) originated in secondary care. Often the rubric associated with codes was re-written by clinicians, which added a further layer of complexity when searching for synonyms. We used only the primary care data, as it is largely the responsibility of primary care providers in the UK to manage BP in CKD patients. The narrative description of the final algorithm is in Table 1. The full algorithm and list of codes used is available from www.clinicalcodes.org.

Table 1. Narrative description of the fully developed algorithm sequence.

Step	Criteria

1	**Patients with CKD**
	• Include patients prior to the study period with:
	  o a CKD diagnosis code.
	  o a most recent mean eGFR<60 or ACR≥30 or PCR≥50 over a >90 day period.
	• Exclude patients with a death code at any time.

2	**Patients in whom it is appropriate to achieve quality standards for BP management**
	• Exclude patients with:
	  o a palliative care code or an orthostatic hypotension code at any time.
	  o an 'informed dissent' or 'unsuitability' code for CKD or BP quality indicators within 15 months of the study period.
	  o a 'maximal BP therapy' code within 15 months of the study period, or who were receiving 4 types of anti-hypertensive medication concurrently (or fewer if they were unable to receive 4 types due to allergies and/or contraindications), at the time of their latest BP measurement.

3	**Patients who have not achieved BP management quality standards**
	• Exclude patients with a DM diagnostic code prior to the study period:
	  o *and* microalbuminuria (defined as a microalbuminuria code at any time or most recent ACR≥3.5 [females] or ≥2.5 [males]) *or* proteinuria (defined as a proteinuria code at any time ACR≥70 or PCR≥100), whose latest BP is <130/80 *and* within 9 months of the study period end.[4,34]
	  o but *no* microalbuminuria or proteinuria (as defined above), whose latest BP is <140/80 *and* within 12 months of the study period end.[35]
	• Exclude patients *without* a DM code and *without* proteinuria (as defined above) prior to the study period, whose latest BP is <140/90 *and*:
	  o within 12 months of the study period end if a hypertension or CVD diagnostic code is present prior to the study period.[36–40]
	  o or within 15 months of the study period end otherwise.[4,32]

4	**Patients whose care could have been improved to achieve these quality standards**
	• Count the number of direct and indirect contacts* each patient had with the primary care health system since their last BP measurement or during the period of interest defined in Step 3 (whichever is latest).
	• Count how many patients with a high BP reading whose:
	  o Last BP reading is within 2 months of the study period end.
	  o Medication did not change.
	  o Medication changed.

Key: ACR: albumin:creatinine ratio (mg/mmol); BP: blood pressure (mmHg); CKD: chronic kidney disease; CVD: cardiovascular disease (ischaemic heart disease, peripheral arterial disease, stroke, or transient ischaemic attack); eGFR: estimated glomerular filtration rate (ml/min/1.73m^2); PCR: protein:creatinine ratio (mg/mmol).

* Direct contact: face-to-face or telephone contact; indirect contact: medication prescription or administrative activity where the EHR has been accessed.

As we used UK EHR data, we developed the algorithm based on clinical guidelines and standards issued by the National Institute for Health and Care Excellence (NICE)[41] – the authority for clinical guidelines in the UK. To determine whether a patient had a CKD diagnosis according to biochemical parameters in the guidelines (rather than simply a diagnostic code), we took an average of their most recent readings over a period of more than 3 months to account for any fluctuations, and by discounting readings of zero related to eGFR. When the NICE CKD guidelines did not cater for certain cohorts of patients (e.g. those with diabetes but without microalbuminuria, or those without diabetes), we identified appropriate clinical standards from other related NICE guidelines. Interestingly, we could not find NICE guidance on how often CKD patients without hypertension, diabetes or cardiovascular disease should have their BP measured, so we used the standard of 15 months in the UK Quality and Outcomes Framework.[32] We discounted patients from these quality standards (Step 2) based on our clinical experience and on rules used in the Quality and Outcomes Framework.[32]

We classified anti-hypertensive treatment according to the 6 groups in NICE guidelines: (1) ace-inhibitors and angiotensin-receptor blockers; (2) calcium channel blockers; (3) beta blockers; (4) thiazide-like diuretics; (5) other diuretics; (6) alpha-blockers. When a patient had a high BP reading, we ascertained whether there had been a change in medication by analysing the medication prescribed 63 days either side of the reading to account for bi-monthly prescriptions. We defined whether or not a patient's treatment could be optimised based on the number of medication classes they were prescribed, taking into account their allergies and other contraindications: beta-blockers should not be prescribed to asthmatics; beta blockers and calcium-channel blockers should not be prescribed in moderate-severe aortic stenosis (unless surgically repaired); thiazide-like diuretics should not be prescribed where the latest eGFR<30 ml/min/1.73m^2; diuretics should not be prescribed if the most recent serum sodium<130 mmol or potassium<2.5 mmol; all medications should be avoided in pregnancy except for labetalol or methyldopa; ace-inhibitors and angiotensin-receptor blockers should be prescribed if the most recent serum sodium <130 mmol or renovascular disease is present (unless surgically fixed). We defined maximal anti-hypertensive therapy as being prescribed four concurrent classes of medication,[4] or fewer if patients were unable to receive additional medication due to allergies or the above contraindications.

To identify whether patients had on-going contact with the health system, representing opportunities to improve their care, we classified contacts on any given date as follows: the presence of a code denoting direct contact with a patient (e.g. 'home visit', 'medication review with patient'), examination, symptom, history, diagnosis, or telephone contact counted as a 'direct contact'; everything else was classified as an 'indirect contact' including 'failed encounters', issuing of medication, or administrative activities such as reviewing letters from the hospital.

We categorized patients with high BP measurements needing repeat measurement as those who experienced a change in anti-hypertensive medication following the high reading. We also categorized those who had their high reading within 2 months of the final date of the data extract as requiring a repeat measurement, as this was considered a clinically reasonable period to re-check BP after advising lifestyle changes and therefore did not necessarily indicate sub-optimal management.

Algorithm accuracy study

Participants: We applied the final algorithm to 532,409 individual patient records from the whole Salford dataset to assess the quality of BP management in CKD patients between 2011 and 2012. Please see Figure 1 for a detailed breakdown of results. A total of 11,097 patients had CKD: 8,606 (72%) determined by diagnostic code and 2,491 (21%) determined by biochemical parameters. Of these, 1,435 were excluded from the quality standards: 1,226 (85%) due to the presence of a relevant exclusion code and 229 (15%) due to inferences that they were already prescribed maximal anti-hypertensive medication. Following their removal, over a half the remaining patients (4,940 out of 9,662; 51%) did not achieve quality standards for BP management: 2,072 did not receive a BP measurement and 2,868 had a BP measurement above target. Due to word count limitations, clinical and demographic characteristics of the study population are not presented here but are available on request from the authors.

Test results: Of the 2,072 without a BP measurement, 595 (29%) had ongoing direct contact with primary care, which suggests that their BP could be measured at their next visit. This could be used to create a reminder system for providers prior to the patient's next consultation. A further 64 (3%) had ongoing indirect contacts with primary care, suggesting they could be invited by letter, telephone or text message to arrange a BP measurement. This could be used to automatically send letters or text messages to these patients, or present providers with a list of the patients to telephone. Over two-thirds of this cohort (1,413; 68%) had no contact with primary care. This group is more difficult to draw conclusions about. They may require a different approach than simply inviting by letter, telephone or text message; this may be best guided by local provider knowledge. Of the 2,868 with a BP measurement above

target, 1329 (46%) patients did not receive any change in anti-hypertensive medication and may therefore benefit from optimization of their treatment. This could be used to create an alert system for providers to change these patients' medications; they could be contacted via the appropriate methods described above to implement these changes. A further 365 (13%) experienced changes to their medication regime (which may have included patient non-adherence) but did not have a repeat BP measurement to check the consequences of the change. Of these patients, 305 (84%) and 56 (15%) of patients had ongoing direct and indirect contact with primary care respectively, which represented missed opportunities. This information could again be used as a basis for provider reminders, lists or automatic methods of communication to patients to facilitate BP monitoring. Finally, 1,174 (41%) had their BP measured in the last 2 months of the study period, who also require repeat measurements but may not necessarily represent sub-optimal care. This information could be used as described above when the 2-month period has expired, but in the meantime should not be used as an indicator of suboptimal care.

Estimates: 3,766 patients were considered 'positive' by the algorithm (i.e. did not receive care in accordance with best practice but whose care could be improved upon). On manually reviewing the coded information in 100 randomly selected full patient records from 35 different primary care providers within this cohort (not used in the development of the algorithm), clinicians agreed that 90 were truly 'positive'. No cases needed further discussion. The 10 false positives were deemed to have been incorrectly classified as CKD patients by the algorithm.

Discussion

Summary of findings

This study developed and estimated the accuracy of an algorithm that can search EHR data to feed back practical, actionable information to clinicians regarding how they could improve care for patients in accordance with clinical guidelines. We used BP management in CKD patients as an exemplar and achieved a PPV of 90% (95% CI 82%-95%). Following the application of our algorithm we found 4,490 (51%) CKD patients did not achieve BP quality standards, and 3,766[†] (76%) of these patients had obvious room for improvement in their care – either by optimizing medication or taking opportunities to monitor BP. This information has greater utility than current informatics tools that provide audit and feedback using EHR data, because it provides actionable detail for practitioners to follow rather than simply reporting proportions of patients achieving standards of care[11,14,24–28]. The digital artefacts of this kind of retrospective, continuous analysis could provide the missing link between clinical audit and decision support – reducing the latency between clinical quality information and practitioners' improvement actions/tactics for patients with long-term conditions.

Strengths and weaknesses of this study

A major strength of this study is the thorough process through which the algorithm rules were developed. We based the rules on widely accepted clinical guidance, and used our clinical experience to ensure that the algorithm assessed care quality according to both robust research evidence and the clinical service context. These were further refined to ensure their accuracy by manually reviewing 440 different patient records. In addition, we used the totality of patient records to gain a representative picture of how care is delivered across the local population.

A weakness of this study is our reliance on the coded data within the EHRs to validate the algorithm. We were unable to gain access to the full patient EHR, and it is possible that free-text within the records not reflected in the coded data would detail reasons why some of the patients identified by the algorithm did not achieve the BP quality standards. However, many official processes in UK primary care such as health service planning and pay-for-performance rely on coded data, so any important information not entered as codes into EHRs is likely to be minimal.

We did not calculate the negative predictive value (NPV) of the algorithm due to restrictions on the number of patient records we could reasonably review manually. The prevalence of CKD patients that could have their BP management improved is relatively low in the general population and would therefore require large sample sizes to achieve an acceptably narrow confidence interval. However, as this algorithm is intended as a screening tool to lead to further investigation of patient records, it is arguable that a high PPV is the most important statistic to avoid over-burdening clinicians with false positive results.

[†] Taking into account the PPV of 90% this is 3,389.

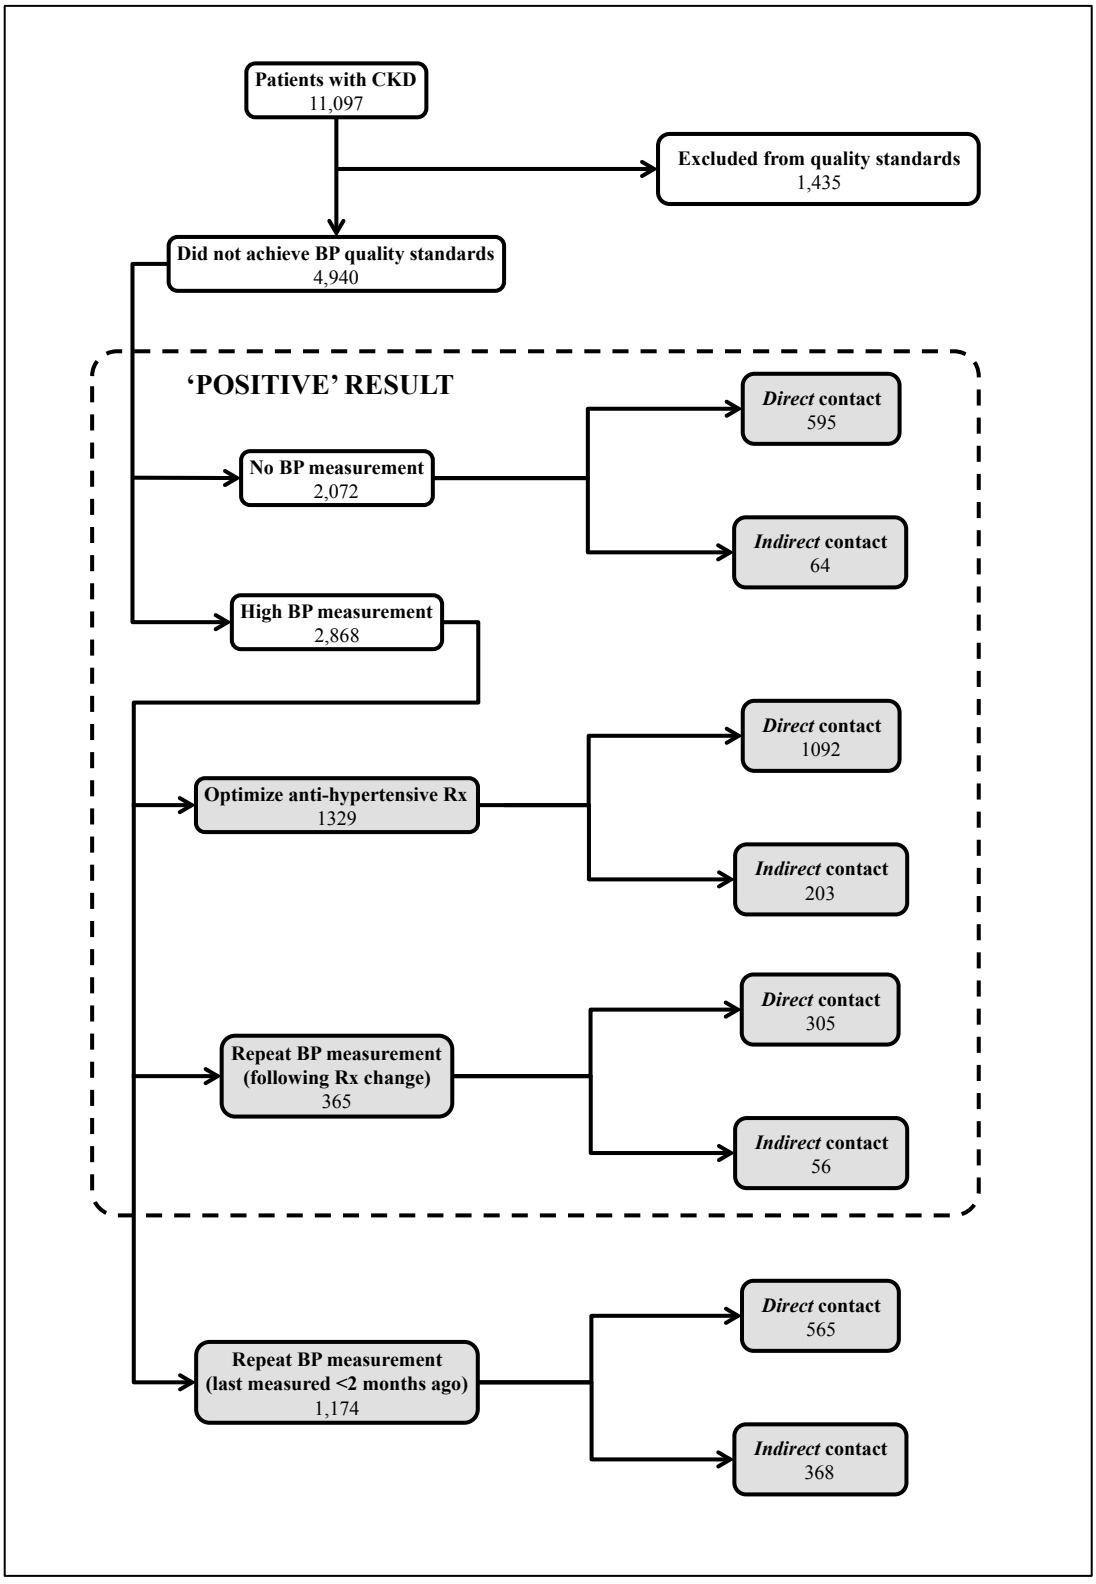

Figure 1. Flow of patients identified by the algorithm.

Key: BP: blood pressure (mmHg); CKD: chronic kidney disease; Rx: medication prescription; shaded areas represent actionable care improvement information for practitioners.

Comparison with existing literature

The algorithm we developed addresses a need identified in the literature that audit and feedback should provide information to clinicians that is actionable, in order to drive effective improvements in patient care.[22,23] Few informatics systems currently use EHR data in an automated fashion to provide audit and feedback in this way,[11,14,24–28] making this algorithm a relatively unique quality improvement tool.

Our finding that 49% of UK CKD patients received NICE quality standards regarding BP management is in broad agreement with other studies. De Lusignan et al. found this proportion to be 48-50%,[14] whereas Fraser et al. found it to be 58%.[16] This agreement suggests our algorithm has external validity.

The PPV of our algorithm is higher than others that use EHR data reported in the literature. Algorithms developed by Singh et al. to detect diagnostic errors in primary care achieved a PPV of between 5-21%;[42] Murphy et al. developed algorithms to detect delayed cancer diagnoses and reported PPVs of 58-70%;[43] and Brenner et al. reported a PPV of 15% in their algorithm to identify adverse drug events.[44] These discrepancies are likely explained by differing prevalence and ease of detection from EHR data of the events under examination. Furthermore, because we were unable to view the free-text within the patient records, the true PPV of our algorithm may be lower than 90%.

Implications for clinical practice and research

The algorithm developed in this study can form the basis of an audit and feedback tool to improve BP care for patients with CKD. Clinical performance systems that provide practitioners with actionable information on how to improve care, such as this, are more effective than those that simply provide proportions of patients meeting quality standards.[22,23] Thus the algorithm could enable practitioners to reduce cardiovascular morbidity and mortality – and as nearly all UK primary care providers use EHRs that capture Read codes, it could be rapidly deployed.

By relating care quality analyses to a practitioner's individual patients in this way, such a system may also improve clinical coding. This effect may reach beyond the specific codes concerned to a more general increase in coding accuracy as the gap between care quality information and improvement-actions is closed.

This study has tested the feasibility of a method that draws clinical process and outcome measurement closer together, which is likely to improve BP control and CKD outcomes. Our approach could be abstracted to other chronic conditions that use both processes and outcomes, which include (but are not limited to) other longitudinal physiological parameters (e.g. cholesterol, glycated hemoglobin).[45] The method could also be applied to other healthcare settings that employ different coding languages in their EHRs, such as hospitals and different countries.

Future work

Our future work will initially focus on improving the performance of the algorithm (particularly with regard to the diagnosis of CKD) and assessing the accuracy of the actionable information it provides. We aim to compare this with manual reviews of full patient records that include free-text. We also hope to improve the functionality of the algorithm to identify total daily doses of medication to provide more specific advice on how treatment could be optimized, and to assess medication adherence. Ultimately our vision is to use this algorithm to form the basis of an audit and feedback informatics tool by integrating it into software previously developed by our group.[46] We anticipate that the tool could be linked to patients' EHRs and provide clear and succinct messages to providers on how to improve care, taking into account comorbidities, allergies and other relevant patient characteristics. We believe that local clinical ownership of quality improvement projects is fundamental to success, but that clinicians may not have the expertise to develop and implement the informatics tools necessary. We will therefore work with local clinicians to understand the needs of their populations and ensure there is clinical engagement with our work. We are also mindful that implementing such tools into practice must align with existing clinical workflows to be effective and efficient. Therefore our approach to development and implementation of the audit and feedback tool will be iterative, and employ mixed methods techniques informed by relevant theoretical frameworks.[47] The effectiveness of the tool will eventually be tested in a randomized clinical trial.

Conclusion

We have developed an algorithm that uses EHR data to provide practical, actionable information to clinicians on how to improve care – a 'rear view mirror' for long-term conditions management. We used BP management in CKD patients as an exemplar and achieved a useful PPV of 90%. The utility of this information might be improved by mining the related EHR narrative, and by instrumenting clinical coding behavior. In future work we will develop

this approach further in variety of conditions and settings, measuring its effects on clinical behavior and patient outcomes.

The Challenges of Creating a Gold Standard for De-identification Research

Abstract

We created a Gold Standard corpus comprised over 20,000 records of annotated narrative clinical reports for use in the training and evaluation of NLM Scrubber, a de-identification software system for medical records. Our experience with designing the corpus demonstrated the conceptual complexity of the task.

Introduction

At NLM we have developed a de-identification software system for medical records called NLM Scrubber intended to automatically de-identify clinical reports in compliance with the Privacy Rule of Health Insurance Portability and Accountability Act (HIPAA).[1] In the course of developing the scrubber, we needed to create a manually annotated corpus of medical records to serve as a "Gold Standard" for testing and evaluation. Annotation is needed to demark identifiers that should be found and scrubbed by the de-identification system and to provide enough information to facilitate both evaluation and further development. The nature of the markup in this corpus determines the kind of evaluation that can be undertaken. Ultimately, our corpus consisted of a set of 21,849 tagged clinical narrative reports. In each report, the identifiers meeting the HIPPA requirements for PII (personally identifying information) had to be hand-tagged. We had to make three types of decisions in the process of developing the tag-set. First, the HIPAA rules had to be interpreted and applied to the actual items found in the records. Second, we needed to identify the items themselves as well as their boundaries and third the internal structure of the items needed to be considered. This paper discusses our approach used in this process, outlines our conclusions and discusses alternatives.

Applying the HIPPA Rule

The HIPPA Privacy Rule requires that clinical documents be stripped of personally identifying information before they can be released to researchers and others. HIPAA Privacy Rule describes 18 identifiers that should be scrubbed in the de-identification of medical records.

Some of these descriptions seem quite specific; For example, "[all] elements of dates (except year) for dates directly related to an individual, including birth date, admission date, discharge date, date of death; and all ages over 89 and all elements of dates (including year) indicative of such age, except that such ages and elements may be aggregated into a single category of age 90 or older." But even in this seemingly well-defined rule, there is room for interpretation. Do partial dates without mention of the year count as dates e.g. "July" or "July 23rd"; do special days like "Christmas" or "New Year's" count as dates?

The Boundaries and Structure of identifiers

Identifiers do not always appear in discrete packages with clear borders. Are titles like "Mrs.", "Dr.", "Col." or "Adm." part of the name? What about name suffixes like "Jr." or "III" or titles like "MD", "Ph.D." or "Esq."? Some of them, such as "Mrs.", do not have much identifying information value; whereas, others such as "Adm." May have because of their occurrence in the population. Identifiers can also be conjoined in ways that obscure their structure. "The 5th, 6th and 18th of June 1965" seems to contain three full dates but it also contains lexical material that is not really part of any date, "and" in this case. The question/process of delimiting items is further complicated by the internal structure of those items.

Table 1. Per HIPAA Privacy Rule, the following identifiers must be deleted from PHI to fully de-identify health information. (*) As of 2010, there were 18 sets of zip codes with distinct initial three digits whose corresponding population sizes were less than or equal to 20,000.[2]

1. Names
2. All geographic subdivisions smaller than a state, except the first two digits of the zip code of the postal address. The third digit of the zip code can also be left intact, only if the size of the population in the area of the censored two digits is greater than 20,000 according to the most recent census data.(*)
3. All elements of dates (except year) for dates directly related to an individual, including birth date, admission date, discharge date, date of death; and all ages over 89 and all elements of dates (including year) indicative of such age, except that such ages and elements may be aggregated into a single category of age 90 or older.
4. Telephone numbers.
5. Fax numbers.
6. Electronic mail addresses.
7. Social security numbers.
8. Medical record numbers.
9. Health plan beneficiary numbers.
10. Account numbers.
11. Certificate/license numbers.
12. Vehicle identifiers and serial numbers, including license plate numbers.
13. Device identifiers and serial numbers.
14. Web universal resource locators (URLs).
15. Internet Protocol (IP) address numbers.
16. Biometric identifiers, including fingerprints and voiceprints.
17. Full-face photographic images and any comparable images.
18. Any other unique identifying number, characteristic, or code, except the ones that may be generated by the covered entity for re-identification.

Are single letter initials inside a full name significant, e.g. "Q" in "John Q. Public"? In other words, if the scrubber only misses a middle initial, would the middle initial reveal the identity of the person? If not, should we tag or not tag the middle initials?

Methods

As described in Kayaalp, et. al. 2014,[2] we selected a random sample of patient records from the NIH Clinical Center using a method that prevented duplicate records. The selection involved randomly choosing 7,571 patients, collecting all of their records and removing duplicate records. A linguist and a registered nurse on our research team used VTT (Visual Text Tagger), a freely available text tagging system developed at NLM[3] to annotate PII in each record.[3,4] VTT uses a stand-off method to annotate texts so that both the original text and its formatting are preserved.[5] VTT facilitates tagging by allowing the human tagger to select an area of text by smearing the cursor over it and then choose a tag listed in from a drop down menu. It also provides a visual display of the tagged document representing each tag in a distinct visual format. VTT stores these annotated documents in a pure-ASCII machine readable format. In Figure 1 below, a mock-up version of the sort of records that make up our corpus is shown as displayed in VTT.

At the beginning of the process the human annotators tagged overlapping sets of records and came to a consensus on the results. The annotators conferred on specific questions as they worked through different sets of records. Then different sets of records were assigned to each annotator. Organized by patient, all the records of a particular patient would be completed by the same annotator in succession.

We tagged personal names, dates, addresses, ages and alphanumeric identifiers.

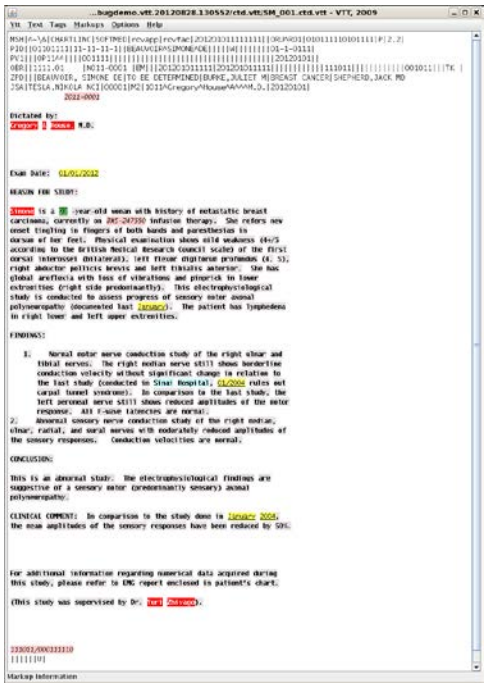

Figure 1

Names

HIPAA specifies that names must be redacted when they refer to patients and their relatives, employers and household members. Names of providers are not considered personally identifying, but almost all de-identifying programs scrub all personal names (care providers as well as patients), and it is probably the safest course because it can be difficult to distinguish between the two. We assigned the tag 'Name' to all personal names in our corpus. VTT allows tags to have subtags further refining the meaning of the tag. This distinction between identifiers related to patients and those not related to patients carries through a number of different tags. A 'Patient' subtag added to the 'Name' tag was used to indicate the names of patients as opposed to the names of hospital personnel and other people mentioned in the records. Names of relatives and members of the patient's household also received the 'Patient' subtag. Names were tagged as whole; that is the entire string "John Q. Public" would be given a single 'Name' tag. Suffixes like "III" or "Jr." were considered part of the personal name and tagged accordingly, but titles like "Mr.", "Dr.", or "Col.", were not unless their occurrences were rare. Initials seen in a longer name string were included in the name. Single first-names and last-names standing alone, e.g. 'John' by itself and "Public" in "Mr. Public", also received the 'Name' tag. Initials standing alone in the text, e.g. 'JQP' or 'JP', were marked 'PNinit' and separated into patient and non-patient using the 'Patient' subtag. While OCR guidelines states that initials are considered names,[6] we separated them because we felt initials were different and perhaps much less identifying than spelled out names. The vast majority of initials that we encountered denoted providers or transcriptionists who used them to sign the record. Names that were neither providers nor patients, for example names appearing as citations to the literature like "Greulich and Pyle", influential authors of articles regarding bone age, or the name of the current president when evaluating a patient's orientation were not tagged at all. These decisions introduced a difficulty in evaluation in those names like 'Greulich' and were counted as false positives when the system labeled them as names.

Addresses

Whole address strings such as "905 Maple Street, Apartment 2, Littletown, Minnesota, 55021" were tagged 'Address'. Cities standing alone like "Baltimore" were tagged as addresses but states and countries, for example "Maryland" and "Argentina", were not in keeping with guidelines of the Privacy

Rule which say that units smaller than a state should be redacted, although Baltimore has a population of well over 20,000, the size limit for Zip-Codes. D.C. was considered a state for this purpose. State-like subdivisions of countries other than the U.S., like "Alberta", were treated as states. Specific locations within the hospital received the 'Location' tag. For example, "OP9" or "3-Northeast" or "Day Hospital" were considered locations.

In a later iteration, we divided the Address tag into 8 tags identifying the street address, unit number, city, state, country, ZIP-code, county, and kept the old address tag as a catch-all. This revision reflected the realization that not all errors in redacting addresses were alike in seriousness. By tagging Address strings whole we made it difficult at the time of evaluation to recognize that redacting "Maryland" and not "Baltimore" from the string "Baltimore, Maryland" would result a violation of HIPAA but redacting "Baltimore" and not "Maryland" would not.

Street address includes strings like "904 South Madison Street" as well as building names and numbers "The Dakota" and "Building 9". The unit number captures apartment and suite numbers. States include U.S. states and their equivalents in other countries, e.g. "British Columbia". ZIP-codes have not been observed to stand alone in our documents. They are individually tagged as part of a larger address. To clarify, a lengthy address like "907 Madison Street, suite #5, Silver Spring, Maryland, 20190, U.S.A" represents 6 entities. A street address "907 Madison Street", a unit number, "Suite #5", a city, "Silver Spring", a ZIP-code "20910", a state "Maryland" and a country "U.S.A". Only the states and the countries need not be redacted under HIPAA.

This breakdown of larger address tags allows us to improve our evaluation by facilitating a more granular understanding of how identifying partially redacted addresses might be. It opens up a better method of counting errors than either a binary question of whether the address was (completely) redacted or a simple count of how many tokens or what percent of the address was redacted. The best evaluation might count the number of identifying parts that are redacted or better yet we should consider an evaluation of how identifying the unredacted parts are. For example "907", "Suite #5" or even "Madison" alone without the rest of the address could hardly be considered identifying.

Alphanumeric Identifiers

Alphanumeric identifiers were defined as strings of letters and/or numbers used as identifiers, excluding those identifiers that are part of a personal name, address, date, and age. We divided them into three different types: communication identifiers, protocol numbers and other Alphanumeric Identifiers, receiving 'Comm', 'Prot', or 'Alphanum' tags respectively. HIPAA calls for all of these identifiers to be redacted. A 'Comm' tag was assigned to Communication identifiers included numbers such as telephone numbers, email addresses, URLs and the like. Protocol numbers were common in our corpus and have a fairly typical form. The remaining numbers comprised the Other Alphanumeric identifiers and came from a range of types, including sample numbers, blood unit numbers, radiologic ids and lab test numbers. Communication number may or may not pertain to a patient so 'Comm' tags can take the patient subtag depending on whether they pertain to the patient. The telephone number of a referring physician would be marked 'Comm' but without a 'Patient' subtag. Protocol numbers and other alphanumeric identifiers were all considered patient related and subtagged 'Patient'.

Ages

We used three tags 'Age-PII' and 'Age-NPII' and 'Age-fract' to mark ages found in the corpus. Age-PII identified ages 90 years and over, since HIPAA specifically requires that ages over 89 be redacted. Age-NPII was used to mark ages in years, less than 90 which are not PII. Ages less than a year e.g. "3 days", "2 ½", "fifth week of life" belong to a special case, because they were not singled out by HIPPA as PII but they certainly could be much more identifying than an age in whole years. In the case of 'Age-PII' and 'Age-NPII' only the numeric part of the age was tagged, e.g. in "patient is 56 years old", we only tagged "56". In the case of age ranges like "3-5 years" only "3" and "5" were tagged. Ages given as decades, e.g. "in his 60's", were not tagged because they represented so large an age span that they were not considered identifying. In the case of fractional ages, both the number and the unit of measure were included in the tag, for example "thirteen months" and 'three weeks' would be tagged 'Age-fract'. By

keeping the unit of measure we allowed the de-identification system to round these ages to a year or redact them completely. All three age tags were used to mark only the ages of patients, their relatives or household members. No provider ages were seen in our corpus. Gestational ages and bone ages were not tagged 'Age'.

Dates

Date strings were initially tagged whole in our first iteration. "Wednesday, June 14, 1996" was tagged as a date as were free standing date parts. Months like "February", days like "Thursday" and years like '1998' when standing alone in text were tagged 'Date'. Decades like "The 60's" and plural days, "Fridays" were not tagged because such long or repetitive dates were not considered identifying. By default all dates were considered to be relevant to patients. In date ranges like "June 3 – July 15" both the beginning and end points are tagged as dates, separately. An exception appears when part of the range is unable to stand on its own, e.g. "2005-6". In this case the whole string was tagged. We considered special days like "Christmas" or "Mother's Day" to be dates and tagged them as such since they are equivalent to a date like 'December 25". Although HIPAA requires redaction of all elements of Dates except the year, strings like "September 23rd" standing alone don't indicate a specific date unless they are in the context of a year. But since HIPAA allows years not to be redacted we should assume that there might be a year in context depending on how the de-identification run is configured. Days of the month standing alone are another matter since "the third" or "the third of the month" does not specify a particular date and would only do so in conjunction with a month name and a year. Since month names must be redacted under HIPAA, weekday names would not be particularly identifying.

Similar to our treatment of Address, in a later iteration of our tagging effort we broke Dates into their parts again facilitating a more granular evaluation. By tagging months, days and years separately in a long date string like "February 27th, 1991" we can not only take account of the fact that the substring "1991" need not be redacted at all, but we can also consider that "27th" without the month does little to identify that actual date even in the presence of the year.

This more granular approach to tagging also facilitates treatment of conjoined and otherwise obscured items. For example the date string "the 5th, 6th, and 18th of May" presents several difficulties for evaluation. The tokens "the", "and" and "of", though parts of the date string, are not really parts of the three dates represented here and might be ignored during evaluation. By tagging "May" as a month and "6th" as a day we will be able to recognize that "May" alone is identifying in a way that "6th" alone is not, even in the context of a year.

Revision of other tags

Although we have not yet moved to a more granular treatment of other identifiers, it would clearly help our evaluation to do so. In the course of evaluation we decided not to count single initials that are part of a name like the "H" in "William H. Macy" as a name token. That is, we did not consider it a false negative if it was left unredacted when the rest of the name was redacted. Although this situation seldom arose imprecise because the scrubber was generally able to recognize middle initials from their position between two name tokens. That decision points to a future re-tagging of the corpus to reflect the parts of full names. Similarly, telephone numbers might be sub-divided into the area code prefix and number. Area codes and prefixes have a geographical association and might be considered more identifying than the 4 digit number itself. HIPAA already contemplates the internal structure of ZIP-codes specifying that the initial three digits of the ZIP code need not be redacted if "The geographic unit formed by combining all the ZIP codes with the same three initial digits contains more than 20,000 or fewer people." Something similar might be applied to telephone area codes or prefixes.

Results

We annotated a total of 21,849 records, representing 7,571 patients. Of those records, 3093 were used for evaluation in our de-identification study[2] and 1,140 were used for training. In addition to the two iterations of tagging, errors found in the course of evaluation were fed back into the gold standard after review by the taggers.

Discussion

The creation of our gold standard represented a number of challenges as described above including the lack of clear definitions of redactable items. One of the main lessons to come out of the effort was the realization that a finer grained analysis of strings representing PII facilitates a better understanding of evaluation results and points to a better method of evaluation. Counting whole strings as either properly redacted or not does not take into account which parts of the string might be left unredacted. Using token counts in the calculation of sensitivity and specificity also has inherent drawbacks, especially when a singly revealed token is a part of a multi-token identifier such as “September 11, 2001.”The potential of a particular token to identify the patient is less clear than the potential of properly tagged parts of the whole string.

Another consideration not explored above is the possibility of tagging more than the PII in a file. We found our evaluation hindered by a lack of knowledge about which tokens could be removed without loss of clinically pertinent information. Examination of actual redacted records shows that precision based on the number of false positive tokens overestimates the loss of information in actual records. Natural language including the sublanguage of clinical records is sufficiently redundant so that the loss of tokens often does not result in a significant loss of readability. Some sections of the record will inevitably contain information not relevant to a particular medical task and loss of that information would not damage the usefulness of the record. We are exploring a methodology to identify and subsequently tag clinical information so as to rationalize future evaluation of precision in our de-identification effort. The challenge in this task would be similar; that is, how should we categorize clinical information and label it with finer granularity so that we can fairly measure the loss of clinical information?

Abstract

Adoption of electronic clinical data exchange (CDE) across disparate healthcare organizations remains low in community settings despite demonstrated benefits. To expand CDE in communities, New York State funded sixteen community-based organizations to implement point-to-point directed exchange (n=8) and multi-site query-based health information exchange (HIE) (n=8). We conducted a cross-sectional study to compare adoption of directed exchange versus query-based HIE. From 2008 to 2011, 66% (n=1,747) of providers targeted for directed exchange and 21% (n=5,427) of providers targeted for query-based HIE adopted CDE. Funding per provider adoptee was almost two times greater for directed exchange (median (interquartile range): $25,535 ($17,391-$42,240)) than query-based HIE ($14,649 ($9,897-$28,078)), although the difference was not statistically significant. Because its infrastructure can cover larger populations using similar levels of public funding, query-based HIE may scale more broadly than directed exchange. To our knowledge, this is among the first studies to compare directed exchange versus query-based HIE.

Introduction

Electronic clinical data exchange (CDE) across disparate healthcare organizations has the potential to improve care delivery, strengthen public health efforts, and reduce costs (1,2). For large academic medical centers, sharing clinical data with other institutions has been associated with decreased laboratory test ordering (3) and emergency department charges (4). Additionally, regional efforts promoting CDE usage in emergency departments have been associated with reduced costs (5,6). Despite the demonstrated benefits of CDE, widespread adoption remains low (7), particularly in smaller community settings (8).

To increase adoption of CDE, multiple organizational and technological options exist. Non-profit health information organizations (5), accountable care organizations (9), market-oriented health information technology vendors (10), incentives-driven independent healthcare practitioners (11), and health-minded consumers are pursuing different clinical goals, financial motivations, and administrative structures for CDE. Technological approaches for CDE include point-to-point directed exchange of clinical data such as laboratory results and patient referrals, query-based health information exchange (HIE) for aggregating patient data from multiple sites, and consumer-mediated exchange using personal health records (12). The multiple forms of exchange address different but complementary clinical information needs (11).

Despite the diversity of available CDE approaches, studies comparing organizational and technological configurations for CDE are limited, and optimal approaches to CDE are unknown. In New York State, two types of community-based organizations received funding to implement CDE as part of an effort to create a statewide health information network; clinically affiliated groups of providers implemented directed exchange, and regional organizations implemented query-based HIE. The objective of this study was to compare adoption of and barriers to the two CDE approaches.

Background

New York State has 19 million residents and 91,918 healthcare providers, of which 75% (n=68,898) are physicians (medical doctors (MDs) and doctors of osteopathic medicine (DOs)) (75%) and 25% (n=23,020) are physician extenders (nurse practitioners (NPs) and physician assistants (PAs)) (13). Defined policies for CDE exist in New York State. Directed exchange of patient data does not require affirmative patient consent, as point-to-point data

transmission mimics existing fax and telephone-based clinical information sharing. However, a patient must opt in to query-based HIE participation by providing affirmative consent to each healthcare organization that wishes to access his or her data. Clinicians also have the ability to "break the glass" and access query-based HIE during emergencies.

HEAL NY

New York State has invested more than $800 million in health information technology through four phases of the Healthcare Efficiency and Affordability Law for New Yorkers (HEAL NY). Launched in 2006, HEAL 1 invested in community CDE capacity, electronic health record (EHR) adoption, and electronic prescribing. In 2008, HEAL 5 aimed to increase adoption of interoperable EHRs in communities as well as expand and connect multiple community-level CDE efforts to form the Statewide Health Information Network of New York (SHIN-NY). To develop and govern the SHIN-NY, New York State established the New York eHealth Collaborative (NYeC), a public-private partnership with oversight from the New York State Department of Health. Underway at the time of this writing are HEAL 10, which addresses EHR-based patient centered medical home implementation, and HEAL 17, which focuses on EHR-based care coordination; these phases also expand and facilitate statewide CDE. The current study focused on activities funded through HEAL 5.

HEAL 5

To expand CDE in communities, HEAL 5 awarded funding to sixteen organizations of two types: *community health information technology adoption collaborations (CHITAs)* comprised of community-based providers affiliated for care purposes but not under the same corporate umbrella and non-profit, non-governmental *regional health information organizations (RHIOs)* that convened and governed multiple community stakeholders in a defined geographic area. Whereas RHIOs were legally established entities, CHITAs were less formal alliances of providers with leadership from an organization such as a community hospital. CHITAs promoted adoption of directed exchange via software license purchase and implementation assistance of health information technology, particularly certified EHRs, that featured point-to-point interfaces for laboratory result delivery, electronic prescribing, quality reporting, and/or clinical transfer forms. RHIOs promoted adoption of query-based HIE via purchase of software licenses and implementation assistance for standalone web portals and/or EHR interfaces connected to federated or centralized repositories with master patient index, record locator, provider directory, user authentication, and patient consent management services.

CHITAs and RHIOs agreed to participate in a statewide collaboration process and adhere to state technology and policy standards. CDE activities of HEAL 5-funded organizations addressed up to three use cases aligned with state clinical and public health priorities that were based on Office of the National Coordinator for Health Information Technology (14) and Centers for Disease Control use cases (15). Organizations that received HEAL 5 funding also agreed to participate in evaluation activities conducted by the Health Information Technology Evaluation Collaborative (HITEC), the multi-institutional academic consortium charged with evaluating HEAL NY. Members of HITEC conducted this study.

Methods

Using data collected in 2010 and 2011, we conducted a cross-sectional study of organizations awarded funding through HEAL 5 to implement CDE in communities in New York State. Measures included adoption of CDE and barriers to implementation. We compared measures between CHITAs that implemented directed exchange and RHIOs that implemented query-based HIE. Understanding adoption of CDE by providers (16,17) and patients (18) as well as barriers to implementation (19) can inform best practices for CDE. The Institutional Review Board of Weill Cornell Medical College approved this study.

Data collection

To measure adoption of CDE, we obtained data in March 2011 from sources available to the research team. From NYeC, we obtained the number of providers (e.g. MD, DO, NP, PA) who adopted query-based HIE and the number of patients who affirmatively consented to query-based HIE as reported by each RHIO per state requirement. From unpublished survey data collected by the research team as part of general HEAL 5 evaluation activities (20), we obtained the number of providers who adopted EHRs or other health information technology with directed exchange as reported by each CHITA. From HEAL 5 grant applications, we obtained the number of providers and patients targeted for adoption by each organization as well as details about technology implementations. From the New

York State Department of Health website (21), we obtained funding amounts for each organization's HEAL 5 activities.

To measure barriers to implementation, we conducted a survey in November 2010. For each use case that an organization implemented, an organization's executive director (or executive director's designee) rated each of thirteen items as having served as a barrier, served as a facilitator, or had no effect. The thirteen items were based on a previous survey instrument developed and administered by members of the research team (22). If a survey respondent rated an item as a barrier for at least one use case, we considered the item as having served as a barrier for the respondent's organization. The survey contained four other sections not used in the current study addressing organization and governance, financial sustainability, statewide collaboration, and federal context.

Data analysis

We compared adoption of CDE and barriers to implementation between CHITAs and RHIOs. We determined descriptive statistics including mean (±standard deviation (SD)) for normally distributed data and median (interquartile range (IQR)) for non-normally distributed data. To examine differences between CHITAs and RHIOs, we used Fisher's exact tests for proportions, t-tests for normally distributed data, and Wilcoxcon rank-sum tests for non-normally distributed data. As in a prior study (23), the threshold for statistical significance was $p < 0.2$. To perform calculations, we used the R statistical software package.

Results

100% (n=16) of organizations awarded HEAL 5 funding in 2008 to implement CDE in communities participated in the survey (Table 1). Multiple types of entities led the directed exchange efforts of CHITAs while health information organizations exclusively implemented query-based HIE. Of CHITAs, seven implemented certified EHRs with interfaces, and one implemented a secure web application for facility-to-facility care transitions.

Table 1. Characteristics of organizations that implemented CDE. *Denotes $p < 0.2$

	Total (n=16)	**CHITAs (Directed) (n=8)**	**RHIOs (Query-Based HIE) (n=8)**
Leadership entity			
Health information organization, n (%)	9 (56)	1 (13)	8 (100)
Community hospital, n (%)	3 (19)	3 (38)	NA
Federally qualified health center, n (%)	2 (13)	2 (25)	NA
Long-term care facility, n (%)	1 (6)	1 (13)	NA
Municipal health department, n (%)	1 (6)	1 (13)	NA
Total funding in USD millions			
Total, n (%)	105.1	30.4 (29)	74.7 (71)
Organization, median (IQR)	(3.5-9.4)	2.9 (1.7-5.5)*	9.6 (7.3-12.3)*
Providers targeted for adoption			
Total, n (%)	28,094	2,631 (9)	25,463 (91)
Organization, median (IQR)	738.5 (327.5-2,775)	255 (71-450)*	2,850 (1,000-3,516)*
Patients targeted for adoption			
Total, n (%)	13,419,219	1,054,708 (8)	12,364,511 (92)
Organization, median (IQR)	385,000 (103,628-1,290,640)	95,752 (52,176-207,500)*	1,381,281 (986,500-2,275,712)*
Funding per target for adoption in USD			
Provider, median (IQR)	9,224 (4,309-15,798)	12,292 (10,682-25,836)*	3,914 (2,592-5,917)*
Patient, median (IQR)	13 (8-27)	27 (22-37)*	7 (5-9)*

Compared to RHIOs, CHITAs received 59% less total funding (p=0.003) and targeted 90% fewer providers (p=0.029) and 91% fewer patients (p=0.007) for adoption. However, CHITAs received more than twice as much funding per provider targeted for adoption (p=0.003) and almost three times as much funding per patient targeted for adoption (p=0.002) than RHIOs.

Adoption of CDE

Of all providers targeted by organizations for CDE adoption, 24% (n=7,174) adopted CDE. This included 66% (n=1,747) of providers targeted by CHITAs for directed exchange and 21% (n=5,427) of providers targeted by RHIOs for query-based HIE. As shown in Figure 1, the percentage of providers who adopted directed exchange

through CHITAs (mean (±SD): 70 (±42)) was twice as great as adopted query-based HIE through RHIOs (35 (±26)) (p=0.067). Of note, one CHITA achieved 140% CDE adoption after 25 more providers than the 62 targeted adopted directed exchange. Funding per provider adoptee was almost two times greater for CHITAs (median (IQR): $25,535 ($17,391-$42,240)) than RHIOs ($14,649 ($9,897-$28,078)), although the difference was not statistically significant (p=0.234).

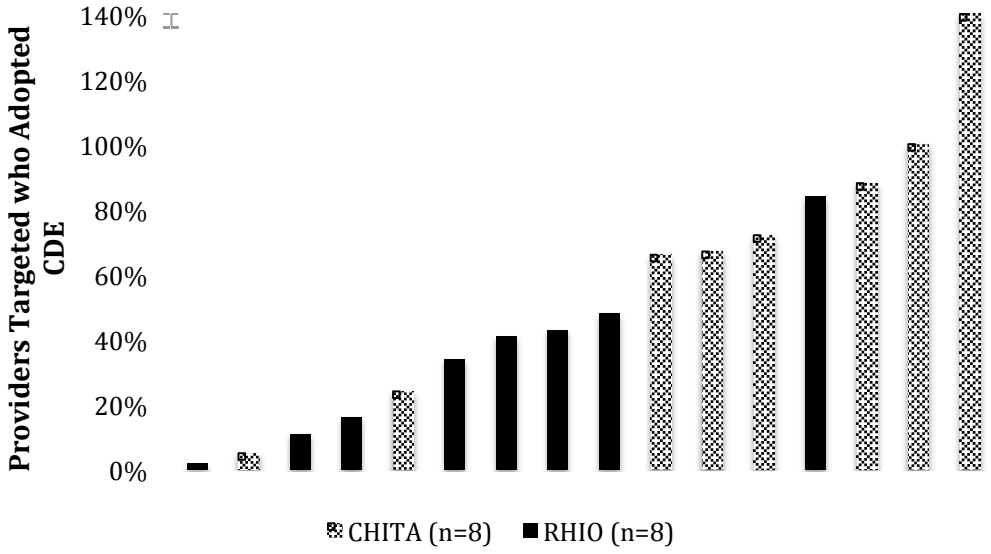

Figure 1. Percentage of providers who adopted directed exchange through CHITAs (n=8) and query-based HIE through RHIOs (n=8).

In total, RHIOs targeted more than 12 million patients to opt-in for query-based HIE adoption per New York State requirement. Of the 1,985,841 patients that RHIOs approached regarding query-based HIE participation during the study period, 1,787,257 (90%) provided affirmative consent, representing 14% of all patients targeted by RHIOs. On average, each RHIO obtained affirmative consent for query-based HIE participation from 16 (±11) percent of patients targeted for adoption (Figure 2).

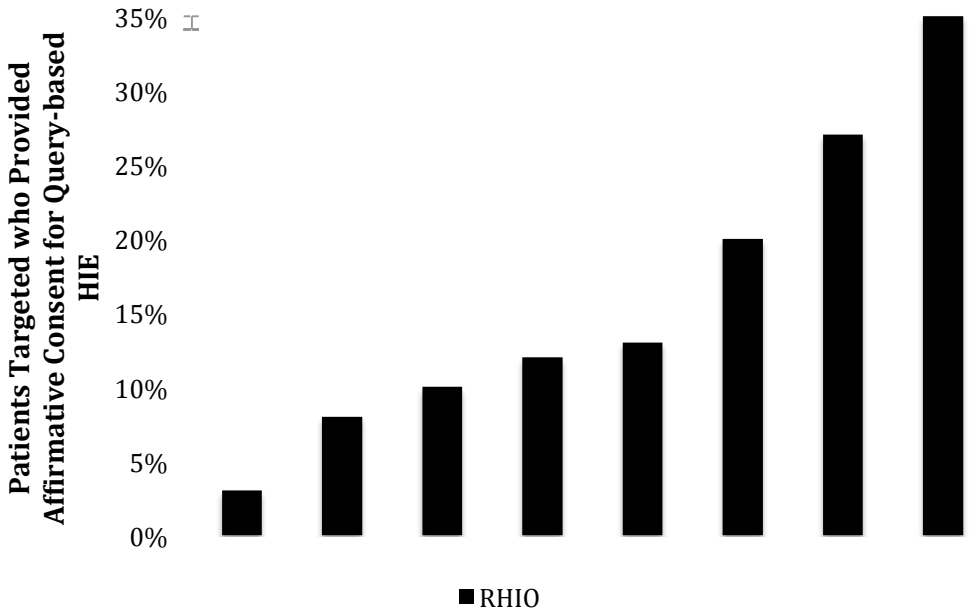

Figure 2. Percentage of patients who adopted query-based HIE through RHIOs (n=8).

Barriers to implementation

Organizations most frequently identified technology maturity (88%, n=14) and vendor participation (63%, n=10) as barriers to implementation (Table 2). Although CHITAs and RHIOs identified barriers similarly in most cases, a greater proportion of RHIOs (88%, n=7) than CHITAs (38%, n=3) identified vendor participation as a barrier to implementation (p=0.118). Vendors for RHIOs included Axolotl, dbMotion, Lawson, InterSystems, MedAllies, and MedPlus while vendors for CHITAs included Allscripts, eClinicalWorks, General Electric, MDLand, Medent, Meditech, NextGen, and Orion Health.

Discussion

This study is among the first to compare adoption of and barriers to directed exchange and query-based health information exchange. Through two types of community organizations, more than 7% of providers and about 9% of patients in New York State adopted CDE between 2008 and 2011. Although a greater percentage of providers adopted directed exchange per CHITA than query-based HIE per RHIO, more than three times as many providers adopted query-based HIE from RHIOs than directed exchange from CHITAs and with New York State funding per provider that was about 50% lower, although not statistically different. Barriers to implementation most frequently identified by organizations were technology maturity and vendor participation, with RHIOs more frequently identifying vendor participation as a barrier than CHITAs.

Federal and state investments have aimed to correct market failure in CDE adoption, but public funding for directed exchange may be to the detriment of existing activities and the public good provided by RHIOs (10). Although financial sustainability of RHIOs is unknown (7) and policymakers expect directed exchange to require less public funding than query-based HIE (10), findings from this study suggest that public funding per provider for query-based HIE may be similar to or lower than public funding per provider for directed exchange. Current federal policy encourages directed exchange that relies on technologies such as provider directories, patient matching, and secure data transport (12), which RHIOs typically already provide for query-based HIE. However, current federal policy does not incentivize use of RHIOs and instead promotes states and commercial entities to build and deliver such services. RHIOs may enable the benefits of CDE to scale more broadly than directed exchange because query-based HIE infrastructure can cover larger populations of providers and patients with similar levels of public funding and more complete data.

As members of Congress question current federal health information technology adoption programs (24) and multiple professional societies request delays to meaningful use deadlines (25), policymakers may find value in revisiting the role of query-based HIE and RHIOs. Existing technology infrastructure for query-based HIE provides a platform for quality improvement, population health management, clinical research, and other rich uses (26). For at least one RHIO, query-based HIE has facilitated care transitions in support of stage two of meaningful use (27), a service other RHIOs can offer to align with provider incentives. Additionally, RHIOs provide a forum for stakeholders to develop trust and govern exchange efforts. For example, health information organizations serving rural areas in the Rocky Mountains and Great Plains recently aligned to support the use of query-based HIE for meeting regional and inter-state patient data needs (28). Query-based HIE and RHIOs add technological and organizational value for CDE absent from current approaches to directed exchange.

Critical attitudes toward vendor-based CDE technology observed in this investigation are consistent with previous reports. In a recent national survey, a quarter of RHIOs expressed concern about "poor customer service, configuration and implementation issues, and cost" of vendor systems for CDE (29). Additionally, small practices and small hospitals have lagged in EHR and CDE adoption (30,31), indicating a need for improved vendor technologies and services in community settings (30,32). Accelerated adoption of CDE, and query-based HIE in particular, will likely require improved relationships between vendors and community organizations.

This study has limitations. First, our sample size was small and statistical comparisons were of borderline significance. Second, self-reported data from community organizations may be subject to respondent bias. Unlike our previous investigations that analyzed HIE system log files (27,33), the current study does not illustrate actual sharing of patient data. Third, unmeasured barriers and facilitators may have affected CDE implementation. Specifically, funding from non-HEAL NY sources may have contributed to adoption of CDE. Additionally, respondents may have interpreted the meaning of barriers differently due to potentially ambiguous definitions. Regardless, results of this study suggest a need to test assumptions about the cost of CDE approaches, including directed exchange (12). Finally, findings may not generalize beyond New York State, as privacy, technology, financial, and other factors may vary.

Conclusion

To our knowledge, this study is the first to quantify differences in adoption of and barriers to directed exchange and query-based HIE. Using similar levels of public funding, query-based HIE may enable broader adoption of clinical data exchange than directed exchange.

Examining the Use, Contents, and Quality of Free-Text Tobacco Use Documentation in the Electronic Health Record

Abstract

Recent initiatives have emphasized the potential role of Electronic Health Record (EHR) systems for improving tobacco use assessment and cessation. In support of these efforts, the goal of the present study was to examine tobacco use documentation in the EHR with an emphasis on free-text. Three coding schemes were developed and applied to analyze 525 tobacco use entries, including structured fields and a free-text comment field, from the social history module of an EHR system to characterize: (1) potential reasons for using free-text, (2) contents within the free-text, and (3) data quality issues. Free-text was most commonly used due to limitations for describing tobacco use amount (23.2%), frequency (26.9%), and start or quit dates (28.2%) as well as secondhand smoke exposure (17.9%) using a variety of words and phrases. The collective results provide insights for informing system enhancements, user training, natural language processing, and standards for tobacco use documentation.

Introduction

Tobacco use continues to be the leading preventable cause of morbidity and mortality in the United States[1, 2]. Worldwide, direct tobacco use is responsible for more than 5 million deaths each year while exposure to secondhand smoke is responsible for over 600,000[3, 4]. Public health initiatives such as Healthy People 2020 Tobacco Use[5, 6], the Centers for Disease Control and Prevention's National Tobacco Control Program[7], the U.S. Preventive Services Task Force[8, 9], and the World Health Organization's Tobacco Free Initiative[10] involve efforts aimed at ending the tobacco epidemic through targeted prevention and treatment strategies for children, adolescents, and adults.

In the last five years, there has been increasing emphasis on the potential role of Electronic Health Record (EHR) systems for identification and treatment of tobacco use. Currently among the Centers for Medicare & Medicaid Services Meaningful Use Objectives[12] is a core measure focused on the recording of smoking status as structured data in the EHR using a specified set of SNOMED CT codes (e.g., for "Current every day smoker," "Former smoker," and "Never smoker")[13] and clinical quality measures for tobacco use screening and cessation intervention[14]. A recent Institute of Medicine report further highlighted the importance of capturing behavioral determinants of health in the EHR and specified nicotine use and exposure among the domains to consider for Stage 3 Meaningful Use[11]. A Cochrane Review of 11 studies that involved using the EHR to improve documentation or treatment of tobacco use found that there were modest improvements and concluded that additional research is needed to understand the role of EHRs in this context[15]. Among these studies was a demonstration project where workflow modifications included incorporating evidence-based prompts in the Epic EHR at Dean Health Systems for guiding the identification of current tobacco users, determining their willingness to quit, and offering a set of tobacco cessation interventions[16]. Recent studies have also described workflow changes such as incorporating medical assistants in the documentation and referral process[17] as well as decision support functionality such as alerts and pre-defined order sets[18].

Within the EHR, tobacco use, secondhand smoke exposure, and related interventions may be documented in various parts as structured data or free-text (e.g., problem list[19, 20], social history[21], medications[19, 22], clinical notes, or patient instructions). A number of efforts have focused on developing natural language processing (NLP) techniques to extract smoking status[23, 24] and tobacco cessation interventions (e.g., searching for the "5 A's" for tobacco treatment and prevention)[25, 26] from clinical notes such as discharge summaries. In a recent study, supplementing structured fields with information from free-text fields was found to substantially improve smoking status data in the EHR[27].

While previous efforts have focused on enhancing the EHR for smoking status and extracting this information from free-text clinical notes, there has been limited discussion on improving the collection of details about tobacco use

(e.g., amount and frequency) and exploring free-text tobacco use documentation throughout the EHR. To this end, the objective of the present study was to examine the use, contents, and quality of free-text comments for tobacco use in the primarily structured social history module of an EHR system. Potential implications of the findings include informing system enhancements, user training, NLP, and standards for tobacco use documentation that may ultimately contribute to improving tobacco use assessment and cessation interventions using the EHR.

Methods

Setting and Study Design

This study involved the retrospective analysis of information collected in the social history module of the Epic EHR (Epic Systems Corporation, Verona, WI)[28] at Fletcher Allen Health Care, the academic health center affiliated with the University of Vermont. This module can be used for primarily structured documentation of tobacco use, alcohol use, illicit drug use, and a range of other social history-related information, which may subsequently be used to pre-populate the social history section in clinical notes. At the time of this study, each tobacco use entry included a set of structured fields associated with smoking, another set of structured fields associated with smokeless tobacco use, and a free-text field for comments (Table 1). Of the 158,608 patients with information documented using the social history module in 2013, this free-text field was used for 18,221 (11.5%) patients where the average length of the comments was 24±19 characters (minimum = 1 and maximum = 255).

Table 1. Example Tobacco Use Entries.

Field	Example 1	Example 2	Example 3
Smoking status	Current Everyday Smoker	Former Smoker	Passive Smoker
Start date	-	-	-
Quit date	-	2/12/02 0:00	-
Types (*Cigarettes*, *Pipe*, or *Cigars*)	Cigarettes	Cigarettes	-
Packs/day	0.5	1	-
Years	15	11	-
Pack years*	7.5	11	-
Smokeless tobacco	Never Used	Current User	Unknown
Quit date	-	-	-
Types (*Snuff* or *Chew*)	-	Chew	-
Comment	Started smoking again in 2010 after quitting a few years	2 cans weekly	Parents smoke outside

** Calculated based on Packs/day and Years*

Three coding schemes were used to manually analyze tobacco use entries in order to characterize: (1) reasons for using the free-text comment field, (2) contents within this free-text field, and (3) data quality issues. The general approach for developing and applying each of these coding schemes (further described below) involved three phases: (1) generating initial coding schemes based on analysis of 100 tobacco use entries from September 2013 and enhancing the schemes using an iterative, consensus-based process involving individuals with expertise in clinical care and biomedical informatics (ESC, EWC, INS, TJW, and GMM); (2) calculating inter-rater reliability using the kappa statistic to ensure consistency in coding between two reviewers (ESC and EWC) using the final versions of each coding scheme for 50 entries from October 2013; and, (3) performing the main analysis on a random sample of 525 tobacco use entries from November 2013 by one reviewer (ESC) where this sample size was based on a total of 4,056 most recent entries for patients during this time, confidence level of 95%, and estimated precision of 4%.

Analysis of Potential Reasons for Using Free-Text Tobacco Use Comments

The first coding scheme for "reasons for use" was developed for identifying potential explanations for why the free-text comment field was used for each patient. In the initial version of the coding scheme, 16 different reasons were identified, which was expanded to 18 reasons (including one for *Other*) in the final version that were grouped into four major categories: (1) Misplaced or redundant information in free-text, (2) Missing values for available structured fields, (3) Limited capabilities of available structured fields, and (4) Other (Table 2). Comments could be associated with one or more potential explanations. For example, the comment "Occasional cigar" would be coded with two reasons: (1) *Misplaced – use Type field* and (2) *Limited ability to describe frequency*. One reviewer then analyzed the set of 525 entries to determine the most frequent reasons for using the free-text tobacco use comment

field. Inter-rater reliability between two reviewers for the set of 50 entries (almost 10%) was calculated using Cohen's kappa, achieving κ of 0.91 for coding reasons.

Table 2. Coding Scheme for Reasons.

#	Potential Reason	Brief Description	Example Comments
Misplaced or Redundant Information in Free-Text			
1	Misplaced – use Smoking status field	Smoking status field includes 10 values, including "Heavy Tobacco Smoker" and "Passive Smoker"	• hx of heavy tobacco use • exposed to second hand smoke
2	Misplaced – use Packs/day field	Could be entered using Packs/day field	• 50 years 2ppd = 100+ pack-years • 30yr x 0.5 ppd
3	Misplaced – use Years field	Could be entered using Years field	• 50 years 2ppd = 100+ pack-years • 30yr x 0.5 ppd
4	Misplaced – use Type field	Could be entered using options for Types (e.g., cigarettes, pipe, or cigars)	• Occasional cigar • Pipe
5	Misplaced – use Start or Quit date field	Could be entered using Start or Quit date fields	• quit 4/3/2011 • Quit just recently. (8/16/13)
6	Redundant Text	Same/synonymous information in comment also entered into structured fields	• Former smoker • nonsmoker
Missing Values in Available Structured Fields			
7	Missing value for Type field	Comment includes type that is not among available values for Type field	• Switched to an inhaler • electronic cigarette
Limited Capabilities of Available Structured Fields			
8	Limited ability to describe amount	Comment includes amount that cannot be described using available fields (Packs/day and Pack years fields)	• 1-2 cigars a day • 2 cans weekly • a few a day
9	Limited ability to describe frequency	Comment includes frequency that cannot be described using available fields (Packs/day)	• Smoked cigars sporadically • occasional pipe • a few a day
10	Limited ability to describe start or quit date	Comment includes a date that cannot be described using Start date or Quit date fields that require mm/dd/yy	• Quit April 2010 • Quit one year ago • Quit 1971
11	Limited ability to describe start or quit age	Comment includes an age related to starting or quitting	• smoked until age 16 • from age 18-26
12	Limited ability to describe duration or timepoint	Comment includes tobacco use or quit duration or timepoint	• Many years • Quit for 10 yr
13	Limited ability to describe situation	Comment includes information about situation or context of tobacco use	• Social • occasional in college
14	Limited ability to describe cessation attempts	Comment includes information about quit attempts, interventions, etc.	• Would like to quit • Working on quitting
15	Limited ability to describe passive smoke exposure	Comment includes information about passive smoke exposure that cannot be described in available fields	• Parents smoke in the home • No second hand smoke
16	Limited ability to specify multiple values	Comment includes additional status, age/date, etc.	• Quit 04/12/2008, restarted in 07/2008, quit 2/2010
Other			
17	Multiple statements	Comment includes multiple pieces of information	• 1-2 cigarettes/day. Quit on /1/13.
18	Other	Any other reason for use	• Smokes marijuana daily

Analysis of Contents within Free-Text Tobacco Use Comments

The second coding scheme for analyzing the "contents" of free-text was focused on categorizing words and phrases within the free-text comments into separate elements. The initial coding scheme included a combination of 10 elements identified in previous work involving the analysis of tobacco use information in clinical notes from multiple EHR systems as well as public health surveys[29, 30]. These elements included: (1) *Status* – current or past tobacco use, (2) *Temporal* – age or date when patient started or quit using tobacco (may be exact or estimated), (3) *Method* – how tobacco is/was used, (4) *Type* – what type of tobacco is/was used, (5) *Subtype* – additional details about type such as brand or filtered/unfiltered, (6) *Amount* – amount of tobacco the patient uses/used, (7) *Frequency* – how often tobacco is/was used, (8) *Certainty* – conviction of source (e.g., patient) regarding tobacco use, (9)

Experiencer – who uses/used tobacco, and (10) *Location* – where tobacco is/was used. An additional four elements were incorporated in the final version of the coding scheme for: (1) *Negation* – absence of tobacco use or exposure, (2) *Duration* – length of time a patient has used or quit using tobacco (explicitly separated out from the Temporal element), (3) *Situation* – context in which tobacco is/was used, and (4) *Cessation* – details about cessation such as attempts, interventions, or treatments.

Each comment was analyzed according to these 14 elements plus an element for *Other* where there could be multiple words or phrases associated with a particular element. For example, the comment "1-2 cigarettes/day" would be coded as Type = "cigarettes," Amount = "1-2," and Frequency = "/day" while the comment "no second hand smoke exposure" would be coded as Negation = "no," Method = "exposure," and Type = "second hand smoke". A κ of 0.94 was obtained for coding contents and main analysis involved determining more commonly used words and phrases for each element where groupings were created to combine those with similar meaning or pattern. For example, the words "chews," "chewed," and "chewing" were grouped together for the Method element while the pattern "*n* years ago" covered specific number of years such as "30 years ago" as well as estimated numbers such as "about 10 years ago" and "over 40 years ago".

Analysis of Data Quality Issues in Tobacco Use Entries

The third coding scheme for "issues" was designed to highlight potential data quality issues based on review of both the structured fields and free-text comment field. From review of the initial 100 tobacco use entries, seven issues were identified that were expanded to a total of 12 data quality issues where an entry could be associated with one or more issues (Table 3). For example, an entry where the value "Never Smoker" is specified in the structured smoking status field while the comment states "OCCASSIONAL CIGAR" would be coded with an issue of *Inconsistent smoking status*. As another example, an entry where the quit date is specified as "11/11/2011" and comment is "quit 2 years ago" would be coded with an issue of *Different temporal references*. Similar to the analysis of reasons for use, a κ of 0.91 was achieved for coding issues and main analysis involved determining the most frequent data quality issues across the 525 entries.

Table 3. Coding Scheme for Issues.

#	Issue	Brief Description	Example
1	Inconsistent smoking status	Contents of comment inconsistent with Smoking status field	Smoking status = Never Smoker Comment = OCCASIONAL CIGAR
2	Inconsistent packs/day	Contents of comment inconsistent with Packs/day field	Packs/day = 1.5 Comment = 01/01/2012 1 pack/day
3	Inconsistent years	Contents of comment inconsistent with Years field	Years = 15 Comment = 10 year smoking hx
4	Inconsistent pack years	Contents of comment inconsistent with calculated Pack years	Packs/day = 1 Years = 50 Comment = 50 years 2 ppd = 100+ pack-years
5	Inconsistent type	Contents of comment inconsistent with Type fields	Types = (not specified) Comment = cigars on occasion
6	Inconsistent start or quit date	Contents of comment inconsistent with Start or Quit date field	Quit date = 8/12/75 0:00 Comment = quit 1980's
7	Different levels of granularity	Contents of comment at different granularity level	Packs/day = 0.5 Comment = 5-10 cigarettes daily
8	Different temporal references	Comment includes relative time rather than absolute time	Quit date = 2/2/05 0:00 Comment = Quit smoking 8 years ago
9	Acronym or abbreviation	Comment includes acronym or abbreviation	• occ. cigar • 2 pks a week
10	Misspelling	Comment includes misspelling	• No smiking x3 days per pt • 3-4 cigarrettes a day
11	Ambiguous	Comment includes ambiguous information	• 2-3/week (*# of times, cigarettes, or packs?*) • 2005 (*start or quit year?*)
12	Not tobacco use	Contents of comment not related to tobacco use	• Smokes marijuana daily • Does not consume alcohol

Results

Based on analysis of the 525 tobacco use entries, Figure 1 depicts the distribution of potential reasons for using the free-text comment field. This field was most often used due to limited ability to describe amount (23.2%), frequency (26.9%), dates associated with starting or quitting (28.2%), and passive smoke exposure (17.9%). In addition, 26.9% of the comments included information considered redundant to what was captured in the structured fields such as smoking status and type.

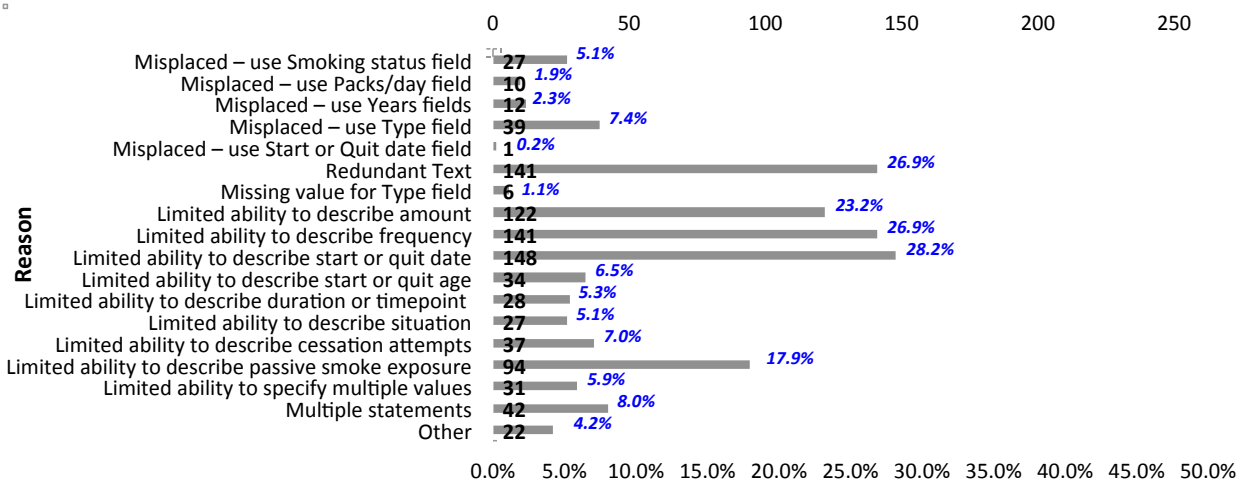

Figure 1. Distribution of Reasons for Use.

With respect to contents, Figure 2 shows the distribution of elements within the free-text comments where words or phrases most frequently described temporal information (38.3%), method (36.6%), type (33.5%), status (31.0%), frequency (29.1%), and amount (28.2%). For each of these elements, Table 4 includes the total number of values (i.e., words or phrases), number of unique values and groups, and the top 3 groups of values along with some examples. For example, of the 220 total values (154 unique values) for the Temporal element that were categorized into 16 groups, 30.0% reflected a specific or estimated year related to use of tobacco or quitting, 27.3% described a specific or estimated number of years ago, and 15.5% provided a specific or estimated age of use or quitting. For the Frequency element, the most frequent words or phrases were related to daily use or use every *n* days where *n* is a specific number or range (50.9%), occasional use (20.0%), and weekly use or use every *n* weeks (13.9%). While occurring less frequently, the majority of phrases categorized as Other were related to decreases in tobacco use (e.g., "cutting back," "down to," and "weaned down") suggesting the need to extend the coding scheme to include an additional element for Change.

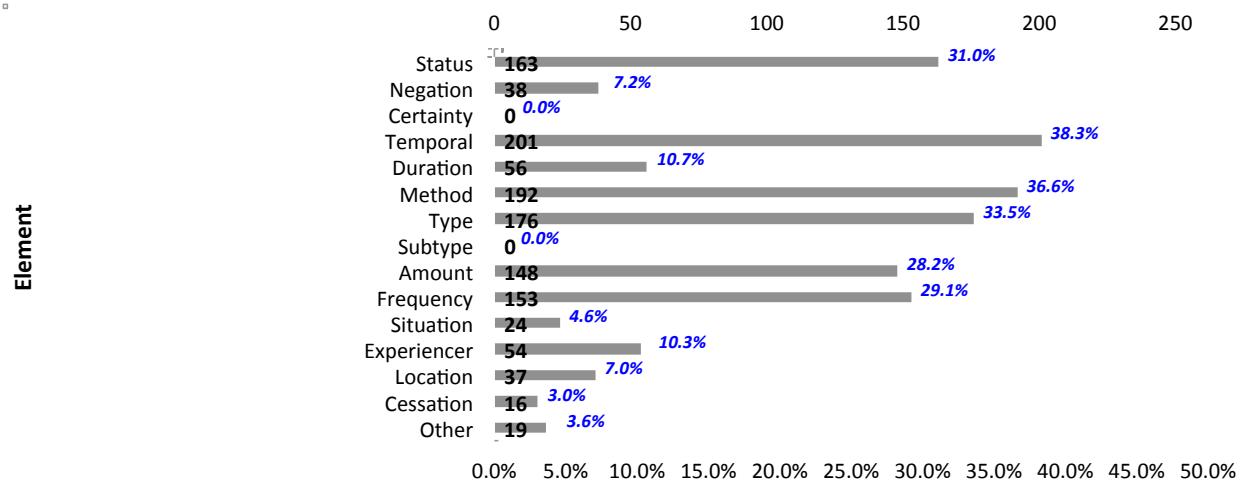

Figure 2. Distribution of Contents.

Table 4. Distribution of Values and Groups of Values for Top 6 Elements.

Element	Total # Values	# Unique Values [# Groups]	Top 3 Groups of Values (*Examples*)	Frequency	
Status	171	24 [8]	• quit (*quit, quitting, former smoker*)	120	(70.2%)
			• smoker (*smoker, smokers*)	18	(10.5%)
			• quit attempt (*trying to quit, process of quitting*)	14	(8.2%)
Temporal	220	154 [16]	• specific or estimated year (*1956, 1970s, early 2000s*)	66	(30.0%)
			• specific or estimated number of years ago (*10 years ago, about 8-10 years ago, over 40 years ago*)	60	(27.3%)
			• specific or estimated age (*age 18, early twenties, teenager*)	24	(15.5%)
Method	195	22 [8]	• exposure (*exposed, exposure*)	110	(56.4%)
			• smoke (*smokes, smoked, smoking*)	61	(31.3%)
			• chew (*chews, chewed, chewing*)	11	(5.6%)
Type	178	36 [13]	• secondhand smoke (*2nd hand, passive smoke, second hand tobacco*)	65	(36.5%)
			• cigarette (*cig., cigs, cigarettes*)	56	(31.5%)
			• cigar (*cigar, cigars*)	25	(14.0%)
Amount	155	85 [17]	• *n* (*3, 7-10, ~8, about 5*)	82	(52.9%)
			• *n* packs (*1/2 pk, 2-3 packs, less than 1 pack, half a pack*)	35	(22.6%)
			• *n* ppd (*1/2-1 PPD, 2-3 ppd, over 1ppd*) *	15	(9.7%)
Frequency	165	60 [22]	• per day or *n* days (*daily, /day, qd, every couple days, 8-10 x/day*)	84	(50.9%)
			• occasional (*occ., now and then, periodically, rarely*)	33	(20.0%)
			• per week or *n* weeks (*weekly, /week, every 2 weeks*)	23	(13.9%)

** addresses both amount and frequency*

Figure 3 reflects the distribution of potential data quality issues associated with the set of tobacco use entries. The most frequent issue was use of acronyms and abbreviations in the comments (18.1%) such as for cigarette or cigarettes where there were 3 different abbreviated forms ("cig,," "cig.," and "cigs") and 2 types of misspellings ("cigarrettes" and "cigarretts"). Other more frequent issues were related to granularity differences (14.1%) such as specifying only the quit year in the comments as opposed to an exact date as provided in the structured quit date field and use of relative rather than absolute temporal references (7.6%) in the comments such as *n* years ago instead of a specific date. Finally, there were several cases of inconsistent number of packs/day (6.7%) that may be due to changes in tobacco use and inconsistent type (5.0%) where the type of tobacco use was specified in the comment but not in the relevant structured fields.

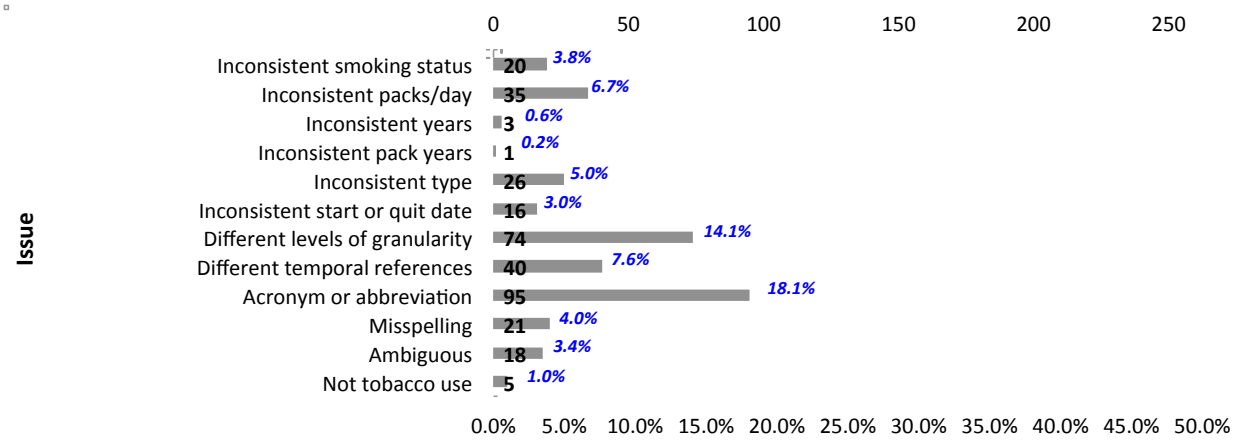

Figure 3. Distribution of Data Quality Issues.

Discussion

The findings of this study provide insights to the current use, contents, and data quality issues associated with free-text tobacco use documentation in the social history module of an EHR at an academic health center. The collective results highlight limitations in capturing details related to tobacco use and secondhand smoke exposure that may be used to inform system enhancements, user training, NLP, and standards for tobacco use documentation. In addition, this work represents a preliminary step towards developing a systematic and semi-automated process for evaluating EHR structure and content. While the study was limited to a single institution with a particular EHR system and focused on a specific module in this system, the overall findings as described below are expected to be generalizable to other institutions that may have the same or different EHR system. It is also anticipated that the three-phased approach for generating, validating, and applying coding schemes to retrospective EHR data could be adapted and applied to accommodate for institutional variations including differences in EHR structure. More broadly, this approach is extensible for performing both quality assessment and content analysis of information in other EHR modules that include free-text and/or structured fields.

The more frequent reasons and contents of the free-text tobacco use comments suggest the need for flexibility in describing amount, frequency, and start or quit dates associated with different types of tobacco or smokeless tobacco (e.g., cigarettes, pipe, cigars, snuff, and chew) that could not be accommodated with existing structured fields (i.e., for packs/day, pack years, and start and quit dates that require that the month, day, and year be specified). Other temporal information within the comments included start age, quit age, and quit duration. Potential system enhancements include incorporating additional structured fields as well as values within existing fields to enable the capture of information such as "occasionally 1-2 cigarettes," "2 cans of chewing tobacco weekly," "quit 1980," "quit in her 20's," "quit x 21 years" in addition to "1 ppd for 5 years" and "quit 2/2/12". The five reasons related to misplaced information (i.e., free-text used instead of available structured fields) were less common; however, they are indicative of gaps in the documentation process that could potentially be addressed through improved user training (e.g., reminders of existing EHR functionality for structured data entry and guidance for when/how to use free-text comments).

While occurring less frequently, there were several entries that included multiple statements or values reflecting changes in status (e.g., patient quit, restarted, and then quit again with associated dates) or amount (e.g., from 0.5 packs to 1 cigarette per day). Such changes could potentially be reflected or re-created by accessing the audit trail for the social history module; however, there may be value in having a more readily-accessible, comprehensive, and flexible "tobacco use history" (or broader "nicotine use history") that could be guided by the findings of this study in addition to existing standards for the representation of tobacco use (Table 5). These standards include those from HL7[31] (e.g., "social history observation," "smoking status observation," and "tobacco use observation" in implementation guides associated with the HL7 Clinical Document Architecture[32-35]) and openEHR[36] (e.g., archetypes for "Tobacco Use" and "Tobacco Use Summary"[37]) that collectively specify the collection of elements and associated values for status, method of use, substance (or type), amount, frequency, start date or age, and quit date or age.

Table 5. Example Tobacco Use History.

Date	Status	Start Date or Age	Quit Date or Age	Duration	Type	Amount	Frequency
2009-07-20	Former	Age: teenager	Date: 30 years ago	Use: 20 years	cigarettes	few	daily
2012-04-16	Current	Date: 2010-08-15			cigarettes	1 pack	weekly
2012-04-16	Current	Date: 2011			cigar	2-3	monthly
2013-10-06	Former	Date: 2011-04		Quit: 6 months	cigar	1	occasionally
2013-10-06	Current	Date: 2010-08-15			cigarettes	0.5 pack	weekly

In addition to describing tobacco use, other uses and contents of the free-text comments were related to secondhand smoke exposure and tobacco cessation (including attempts and interventions). While the list of available values for the structured smoking status field includes one for passive smoking, this is limited to patients who have never smoked and therefore could not be applied to those who were former smokers or who are also current smokers. The occurrence of comments describing exposure or no exposure to secondhand smoke as well as details about experiencer (who smokes – e.g., "parents," "father," or "mother") and location (where smokes – e.g., "outside," "home," or "car") could be used to inform the development of a set of structured fields focused on secondhand smoke exposure.

For tobacco cessation, analysis was performed at a high-level in this study given the breadth of information where further examination is planned to better understand the contents, guide enhancements, and inform how the social history module could promote interventions (e.g., through decision support functionality such as alerts and reminders). As part of this effort, the coding scheme for elements could be extended based on cessation-related elements defined in standards such as the openEHR archetypes for Tobacco Use, Tobacco Use Summary, and Cessation Attempts[37]. Open questions also include determining where and how to document nicotine replacement therapies such as nicotine gum, patches, and inhalers or devices such as electronic cigarettes[38], which were initially coded as missing values for the structured type field when analyzing reasons for use.

Finally, a number of data consistency and other quality issues were noted that could present challenges in using tobacco use information from the social history module for decision support, research, public health, and other primary and secondary uses. In some cases, it was found that information in the free-text comment was inconsistent with the structured fields such as indicating a different status (e.g., never smoker vs. current smoker or former smoker) or number of packs/day where the former could lead to missing or incorrectly identifying patients for tobacco cessation interventions. In other cases, the free-text was found to be the only source of information such as indicating the type of tobacco use (e.g., cigarettes or cigars). For both cases, user training may be one approach for improving and ensuring consistency in documentation prospectively while NLP techniques could be developed to extract details about tobacco use, secondhand smoke exposure, cessation attempts, and interventions both retrospectively and prospectively. Next steps include examining the documentation of tobacco use in other parts of the EHR (e.g., problem list and clinical notes) to further characterize data consistency and quality issues as well as determine how to integrate this information for subsequent uses.

Conclusion

With the increased adoption of EHR systems, there is a need for efforts to explore their potential for improving tobacco use assessment and cessation. This study involved examining the current collection of tobacco use information in the social history module of an EHR with an emphasis on free-text documentation. Based on the preliminary findings, implications for improving the use of information related to tobacco use and secondhand smoke exposure in the EHR include system enhancements, user training, NLP, and standards.

Abstract

Competence is essential for health care professionals. Current methods to assess competency, however, do not efficiently capture medical students' experience. In this preliminary study, we used machine learning and natural language processing (NLP) to identify geriatric competency exposures from students' clinical notes. The system applied NLP to generate the concepts and related features from notes. We extracted a refined list of concepts associated with corresponding competencies. This system was evaluated through 10-fold cross validation for six geriatric competency domains: "medication management (MedMgmt)", "cognitive and behavioral disorders (CBD)", "falls, balance, gait disorders (Falls)", "self-care capacity (SCC)", "palliative care (PC)", "hospital care for elders (HCE)" – each an American Association of Medical Colleges competency for medical students. The systems could accurately assess MedMgmt, SCC, HCE, and Falls competencies with F-measures of 0.94, 0.86, 0.85, and 0.84, respectively, but did not attain good performance for PC and CBD (0.69 and 0.62 in F-measure, respectively).

1. Introduction

National accreditation bodies including the Accreditation Council for Graduate Medical Education (**ACGME**) and the American Association of Medical Colleges (**AAMC**) have called for competency based curriculum and assessment models for training programs. Many medical schools have responded with education portfolios to capture student experiences in real and simulated environments matched to shared competency goals. Education portfolios, however, have not achieved widespread adoption, partially because current methods require significant manual entry of a limited amount of clinical data. Automatic and valid methods of capturing the richness of students' clinical experiences are needed.

In this project, we developed and validated the machine learning based methods used to identify student experiences in six AAMC geriatrics competency domains: medication management (**MedMgmt**), cognitive and behavioral disorders (**CBD**), falls, balance, gait disorders (**Falls**), self-care capacity (**SCC**), palliative care (**PC**), and hospital care for elders (**HCE**). We tested different feature sets such as bag of words, use of biomedical concepts identified through natural language processing (**NLP**), and a refined list of physician-identified concepts corresponding to a particular competency. This work also highlighted the significant challenges for identifying medical student competency from clinical notes.

2. Background

Competency-based assessment methods combine a variety of modalities to provide a comprehensive evaluation of a learner's knowledge and proficiency. [1,2] Medical schools using competency-based assessments typically rely on education portfolios to track students' progress.[3-5] Portfolio components can include personal reflections, examinations, individual and small group projects, simulation encounter reports such as observed structured clinical examinations (OSCEs), mentoring experiences, and clinical exposures. Handwritten log books or score sheets of clinical data,[6,7] replaced now by portable electronic solutions,[8-11] allow students to enter patient information including demographics, diagnosis, procedures performed, and/or severity of illness. Use of these systems is limited for various reasons, including lack of time. Furthermore, teachers often disagree with students on primary diagnoses. We propose a system that automatically captures all concepts in a student's notes and organizes the data automatically to reflect the student's full experience and proficiency along important clinical outcomes.

The AAMC and the John A. Hartford Foundation developed a minimum set of graduating medical student competencies to ensure competent care of older patients by new interns. [12] With the help of leading geriatric educators and survey responses from educators in a number of clinical domains, the consensus panel established

eight core geriatric competency domains. Each competency domain contains 2-5 competencies, outlining detailed goals for medical students in each domain. For example, the "medical management" domain includes 3 subtopics: 1) age related sensitivity to drug selection and dosing based on patient factors (e.g., renal and hepatic dysfunction); 2) identifying medications (e.g., anticholinergic and analgesics) that should be avoided or used with caution in the elderly; and 3) documenting the patient's complete medication list (including herbal and over-the-counter medications) and recognizing possible side effects. These competency domains represent an agreed-upon framework to guide educational curricula and assessment of medical students.

Competency-based assessment may be amenable to clinical NLP and machine learning (**ML**) methods. Prior work has shown that the logistic regression and concept-based queries can identify student exposure to some common presentations, such as chest pain or fever.[13] Such systems are currently being used at Vanderbilt to track student exposure to 16 common presenting problems through the Learning Portfolio website, which captures all student-authored clinical notes.[14] ML-based methods have not been studied extensively in the medical education domain. ML-based models are trained on available annotated datasets, and then applied to new samples to identify their labels. As a preliminary study, we focused on developing ML-based methods to identify six of the geriatric competency domains from clinical notes written by third and fourth year medical students in Vanderbilt.

3. Methods

The automatic competency detection tool consists of three components. The first is Learning Portfolio, a web-based system that gathers all students' clinical notes from patient encounters in the electronic medical record (**EMR**). [15] Portfolio employs NLP, using KnowledgeMap Concept Indexer (**KMCI**) and SecTag to identify biomedical concepts from these notes mapped to Unified Medical Language System (**UMLS**) with their local context (negation and section information). We then applied ML based competency detectors to the NLP output to determine the relevance of a note with respect to different geriatric competency domains based on identified biomedical concepts. Figure 1 illustrates the components used in this project.

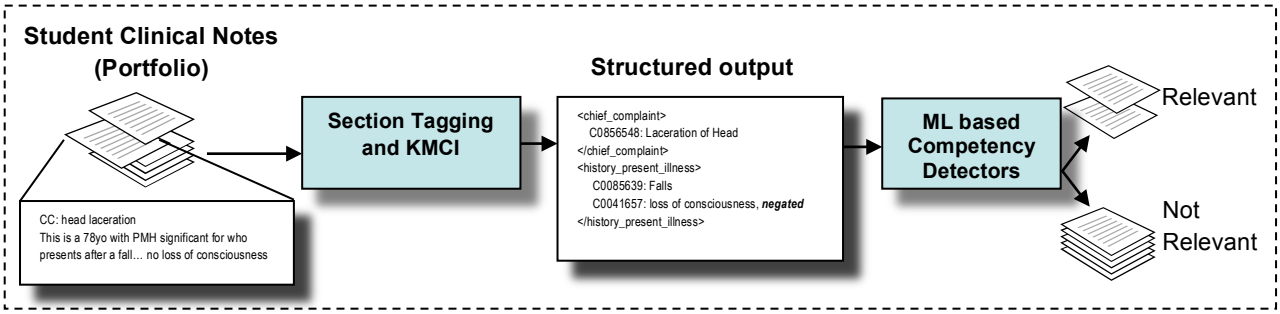

Figure 1. Overview of project: Machine learning based competency detectors assess a clinical note's relevance for each competency based on structured output of the KMCI.

3.1 Section Tagging

We used the **SecTag** section tagger to recognize clinical note sections and their boundaries.[16] The SecTag algorithm uses a concept-oriented, hierarchical section header terminology.[17] In this study, we only used the top sections and some of the first subsections shown in Table 1 as clinician-identified relevant sections. For example, "Family Medical History" under top section "Patient History" is kept as "Family Medical History." Key/first subsections listed in Table 1 replaced their subsections. For example, we have a hierarchical structure of the following sections: Objective Data -> Physical Examination -> Cardiovascular exam. "Objective Data" is the top section, "Physical Examination" is the first or key subsection, and "Cardiovascular exam" is the subsection of the key subsection. Then "Cardiovascular exam" was replaced by "Physical Examination". We also

Table 1. Note sections and subsections for use

- Patient History
  - Chief Complaint
  - History of Present Illness
  - Past Medical History
  - Medications
  - Review of Systems
  - Code Status
  - Health Maintenance
  - Personal and Social History
  - Family Medical History
- Objective Data
  - Laboratory and Radiology Data
  - Physical Examination
- Assessment and Plan
- Problem List
- Reference
- Follow Up
- None

Note: "None" represents the location of words or concepts outside section boundaries.

added a blank section "None" to indicate the content outside of these sections.

3.2 KnowledgeMap Concept Indexer (KMCI)

KMCI is a tool for analyzing unstructured text. For each clinical note, KMCI utilizes UMLS knowledge resources to encode concepts with Concept Unique Identifiers (**CUIs**). Once assigned a CUI, the UMLS provides, for each concept, semantic type information (e.g., "congestive heart failure" is a "disease or syndrome") and relationships to other concepts (e.g., "anterior myocardial infarction" is a type of "heart disease). Locating concepts in the appropriate section of a note can allow an educator or an algorithm to rate a student's mastery of a concept. For example, a search for key concepts related to back pain effectively identifies a note with back pain as a chief complaint, the extent of an appropriate back exam, and the presence or absence of differential diagnoses of back pain found in the student's written assessment.

3.3 Gold Standard of Competency Relevance

Our gold standard note corpus consists of 399 clinical notes from randomly selected inpatients older than 65 years or admitted to the geriatric service and followed by medical students. Geriatric educators rated a student's notes for each admission as containing high, medium, low, or no relevance to each geriatric competency domain. Each reviewer was a board-certified internal medicine physician who was either a geriatrician or has significant experience with geriatrics, including covering the inpatient geriatric service. A total of five reviewers scored each admission. Before scoring, physician reviewers reviewed test sets of admissions and scored them, developing a formal rubric for high, medium, and low/no for each competency domain. Then admissions were scored, disagreements discussed, and consensus achieved. The rubric was developed over the course of several 1-hour meetings of the physicians. The relevance scores of 3, 2, 1, and 0 represent the relevance level from "high", "medium", "low", and "no", respectively. A "high relevance" document contains primary discussion of the components that indicate an experience in that competency domain. In total, 119 admissions were scored by between one and five geriatric educators. For disagreement on scores, we applied the majority vote strategy and finalized the score using the score with the most votes for each student. If scores remain tied, we assign the mean of the tied scores as the final score. We considered students' notes with 'high' or 'medium' relevance (with final score of higher than 1) to have positive relevance and those with 'low' or 'no (with final score of 1 or smaller) to have negative relevance. Table 3 shows the class distribution for each competency domain.

Table 3. Class distribution for six competency domains

Competency Domains	Number of Positive Samples	Number of Negative Samples	Total Samples
Medication Management (MedMgmt)	94 (88%)	13 (12%)	107
Cognitive and Behavioral Disorders (CBD)	46 (43%)	61 (57%)	107
Falls, balance, gait disorders (Falls)	77 (72%)	28 (28%)	107
Self-care capacity (SCC)	78 (74%)	28 (26%)	106
Palliative care (PC)	44 (45%)	54 (55%)	98
Hospital care for elders (HCE)	79 (74%)	28 (26%)	107

3.4 Machine Learning Based Competency Detectors

We applied supervised machine learning techniques to determine a student's experience with geriatric competencies by identifying relevant concepts or other features in the corpus of notes. Experts labeled each case relevant or irrelevant to competency domains. We tested several different feature sets including "Bag of Words" as the baseline feature set, CUIs identified by KMCI, CUIs coupled with Section (SEC), Negation (NEG), and semantic type (STY). We tested other features such as the counts of CUIs in each note as well as the normalized values of CUIs based on term frequency-inverse document frequency (TFIDF). In addition, we added the number of notes in each admission

and the age of patient as two basic features in all experiments. Table 2 shows detailed descriptions of all feature sets in our experiments.

We tried to mimic the way geriatric educators identified the relevance of competency from students' clinical notes. Instead of using all CUIs from the notes, we also tested the feature set with a refined list of CUIs associated with corresponding competency domains, just as geriatric educators use searches for key concepts to assess students' notes. These lists of CUIs were developed by clinicians using web-based tools part of the KnowledgeMap curriculum website,[18] in which complex concept queries are used to track themes in the medical school curriculum. We have previously shown good performance using concept queries of this sort to identify broad themes in the curriculum (e.g., "genetics", "radiology").[18] This reduced the size of features dramatically.

Naïve Bayes (**NB**, the baseline classifier, implemented in CLOP[19]), logistic regression (**LR**), and support vector machines (**SVM**) with linear kernel are three efficient supervised learning tools for the data in high dimensional space. We applied both LR and linear SVM in the package Liblinear. [20] We constructed a classifier for each competency domain using all feature sets including refined lists of CUIs.

Table 2. Description of feature sets used in machine learning experiments

Name of Feature Set	Type of Feature	Description
Note_count	Integer	The number of clinical notes by a medical student for each admission
Age	Integer	Age of patient
Words (baseline)	Binary	Bag of Words features; "1" if word present; "0" if word absent
CUI	Binary	Concept code features; "1" if CUI present; "0" if CUI absent
CUI_NEG	Binary	Concept code with negation: If a CUI is negated in the note, the value of CUI is "0" and the value of CUI_NEG is "1"
CUI_SEC	Binary	Dyad of concept code (CUI) and section: "1" if CUI present in the section; "0" if CUI absent in the section
CUI_count	Integer	The count of each CUI in the notes for one admission
CUI_count_tfidf	Numeric	The TFIDF value of each CUI in the notes for one admission
STY	Binary	Semantic type features (as defined in the UMLS): "1" if semantic type present; "0" if semantic type absent

3.5 Validation

For each competency domain, we ran experiments using 10-fold cross validation for three machine learning algorithms and all feature set candidates. Each fold was stratified so that the distribution of classes in each fold was similar to the original distribution over all samples. These algorithms produced a numeric "relevance score" for the test samples on each fold. We compared the performances of each method with each feature set by computing the average area under receiver operator characteristic curve (AUC) over the cross validation. In addition, using different thresholds for "relevance scores" from the scores of the ML algorithms, we generated different sets of binary predictions and analyzed the precision (i.e., positive predictive values), recall (i.e., sensitivity), and F-measure (the harmonic mean of recall and precision) for all test samples.

4. Results

We evaluated the competencies at the admission level, and a student could write multiple notes for each admission. Totally we had 119 admissions that consisted of 399 clinical notes. There were total 11,249 unique CUIs for all these notes with at least one grade for relevance. Refining this list using just the physician-identified relevant CUIs dramatically reduced the number of features. Given hundreds of refined CUIs for each competency by a geriatric and NLP expert, only 24 CUIs occurred in the notes related to competency domain of medication management, 33 related to CBD, 52 related to Falls, 35 related to PC, 93 related to HCE, and 61 related to SCC. Tables 4 to 9 show the AUC scores for different feature sets and machine learning algorithms for Medication Management, CBD, Falls,

Self-care capacity, Palliative Care, and Hospital care for elders competencies, respectively. The best AUC score for each competency was highlighted in bold.

The SVM classifier generated the models with the best AUC scores of 0.91, 0.76, and 0.69 for competencies MedMgmt, PC, and HCE, respectively. The Naïve Bayes classifier achieved the best models with AUC scores of 0.73, 0.75, and 0.80 for competencies CBD, Falls, and SCC, respectively. For these six best models, we performed a precision-recall analysis based on different thresholds of numeric outputs, or "relevance score", by the classifiers (see Figure 2). The red dot in each graph in Figure 2 represents the precision and recall using the best threshold.

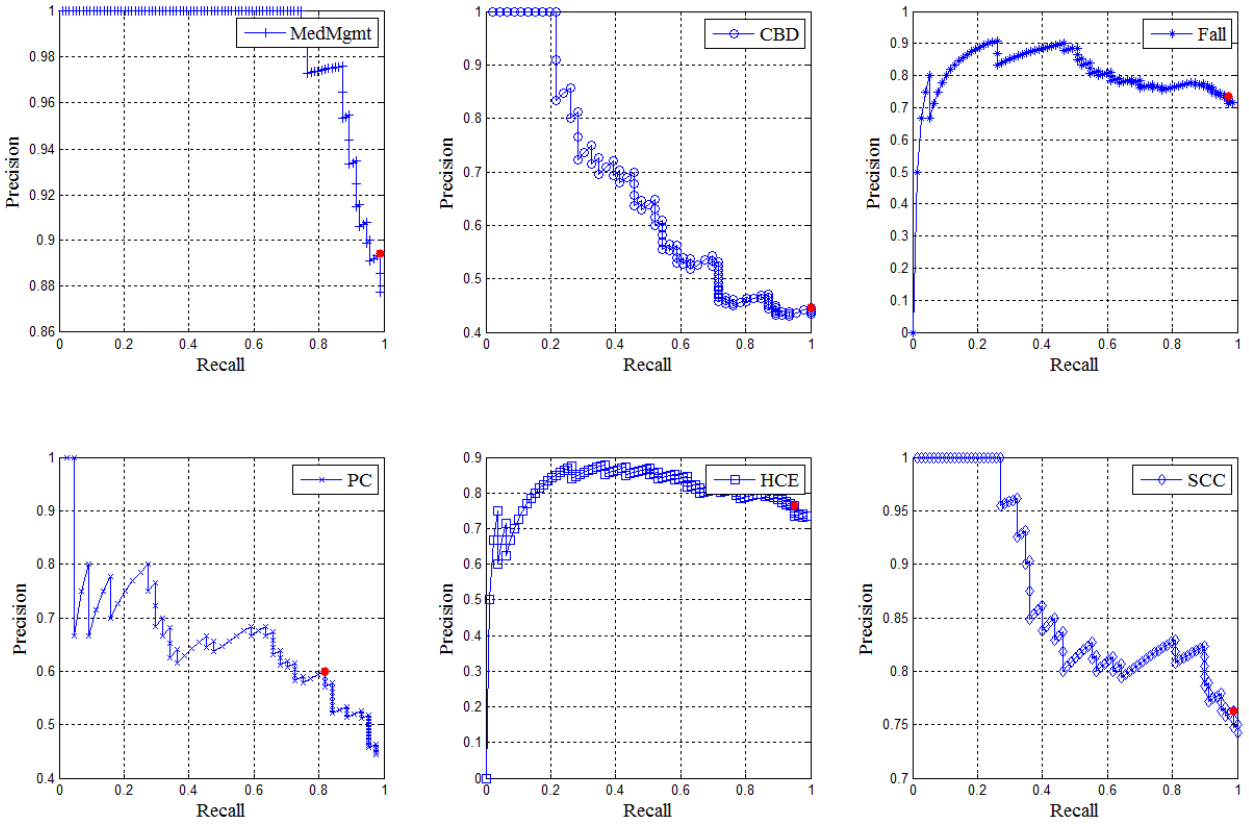

Figure 2. Precision-Recall graphs for the best-performing models for each competency domain. The red dot represents the point with the maximum F-measure (the harmonic mean of recall and precision).

By using the best threshold that can maximize the F-measure (the harmonic mean of recall and precision), we generated the table of precision, recall, and F-measure for each competency in Table 10. ML-model for MedMgmt competency achieved the best result with 0.89 in precision, 0.99 in recall, and 0.94 in F-measure. The next best competencies are SCC, HCE, and Falls with 0.86, 0.85, and 0.84 in F-measure, respectively. PC and CBD are two hard competency identification tasks because the best ML models can only achieve 0.69 and 0.62 in F-measure, respectively.

Table 10. Results of precision, recall, and F-measure for the best model for each competency

	Precision	Recall	Fmeasure
MedMgmt	0.89	0.99	0.94
CBD	0.45	1.00	0.62
Falls	0.74	0.97	0.84
PC	0.60	0.82	0.69
HCE	0.77	0.95	0.85
SCC	0.76	0.99	0.86

5. Discussion

Medical student competency assessment, an ultimate goal of medical education, has typically been largely performed through standardized tests and the subjective assessments of clinical preceptors. This research represents an attempt to implement an objective assessment based on a complete capture of all clinical notes that students write. We chose geriatric competencies due to local interest and 2008 Institute of Medicine report on the importance of geriatrics for the aging US population.[21] We applied NLP and ML methods to 6 of the 8 agreed-upon geriatric competencies as a novel, automated assessment of medical student's competency that are poorly assessed currently, and when they are assessed, it is usually either via a survey or via manual effort by educators. We did not pursue the other two competencies (HCPP: Health care planning and promotion and APD: Atypical presentation of disease) for machine learning. Regarding APD, the physicians failed to resolve an operational definition and consistent rating between them – some Kappas between reviewers for these categories were <0, indicating the difficulty in defining educational competency even despite multiple face-to-face meetings. HCPP was highly unbalanced with respect to the ratio between positive and negative samples, with only 7% of the notes marked as irrelevant to the competency.

This is one of the first applications of NLP and machine learning methods to competency assessment. Based on this preliminary study, identifying the competency domain from the students' clinical notes is a hard problem and requires a variety of features to achieve effective results. The best AUC score of 0.91 in assessing MedMgmt is a desired performance using KMCI CUI counts as feature set. Moreover, methods using NLP methods significantly outperformed "Bag of Words" approaches, whose performance often did not differ significantly from random chance. It is important to note, however, that all of these algorithms had portions of the precision curves in which the precision exceeded 0.8 and 0.9. Such algorithms, implemented with high thresholds, could still significantly enhance upon current methods since they could automatically scan the hundreds to thousands of notes written by clinical students.

We expected that using an expert-refined list of concepts that are highly associated with the competency would improve results, as has performed well in the past.[13,18] In our experiments, the performances on the CBD, Falls, and HCE competencies improved with the refined list of concepts related to the corresponding competency. They are significantly better than the results generated by baseline "Bag of Words". These results told a similar story to the recent I2B2/VA challenge, where most of the research teams used concepts and their related features to improve the text classification performance.[22-26] For the MedMgmt, PC, and SCC competencies, however, the performance decreased with the refined list. This implied that our refined list of concepts for medication management might not be sufficient to cover the entire range of medication management, self-care capacity, and palliative care concepts, or we missed hidden relationships among these concepts that could help the detection. In addition, the best model for each competency domain could generate high recall/precision outcome if we adjust the threshold in figure 2.

Regarding the classifiers we used, Naïve Bayes, Logistic Regression, and linear SVM are all linear classifiers and could run very fast for training. We will try other complex models such as SVM with polynomial or Gaussian kernel[27] and Random Forest[28] to find better models in the future.

Our study has limitation in the following aspects. First, the sample sizes for machine learning are relatively small comparing to other similar NLP tasks. We found the annotation extremely challenging; annotators were spending 30 minutes or more per admission reviewing content for the 8 domains. With the size of training samples less than 150, building a model with high performance when considering multiple documents is extremely hard. Secondly, the quality of annotation result or gold standard in our study is less than perfect. Developing a rubric for relevancy of content was a source of considerable discussion between the physicians. Often, physicians would pick up on subtle hints of disease progression under different situations that would lend them to infer relevance of a given competency – such "hints" of relevance may be difficult for machine learning algorithms to assess. We implemented a majority vote scheme to decide the final label for each admission. There were several cases where the disagreement among raters is high (3 raters voted for high relevance, and another 3 raters voted for low relevance). We have not resolved these cases yet.

In the future, we may try competency detection models at an individual document level instead of a complete admission, as well as a larger annotated set. Machine learning approaches could be more powerful with a refined set of concept related features as well as non-controversial gold standard. Automatic feature section methods could help reduce the dimension of data and extract the most important concept codes with respect to the competency. Expert systems, coupling with machine learning approach, may improve the performance by incorporating the domain knowledge in medical education. Finally, we intend to extend our study to refine the models for all geriatric competency domains by constructing more reliable labels for the training data and test more types of NLP feature sets.

6. Conclusion

In this study, we used machine learning approaches to automate the assessment of geriatric competency for medical students using their clinical portfolios. Use of NLP to generate concept related feature sets as the input of machine learning based competency detectors improved performance. We found use of a physician-generated list of concepts to be our best performing feature set for 3 out of 6 competency assessment tasks. Our model could achieve optimal performance for MedMgmt, SCC, HCE, and Falls with high F-measures, and achieved high precision at some score threshold for all tested competencies.

Exploring the use patterns of a mobile health application for alcohol addiction before the initial lapse after detoxification

Ming-Yuan Chih, PhD, MHA, University of Kentucky, Lexington, KY

Abstract

How patients used Addiction-Comprehensive Health Enhancement Support System (A-CHESS)[1], a mobile health intervention, while quitting drinking is worthy exploring. This study is to explore A-CHESS use patterns prior to the initial lapse reported after discharge from inpatient detoxification programs. 142 patients with alcohol addiction from two treatment agencies in the U.S. were included. A comprehensive set of A-CHESS use measures were developed based on a three-level system use framework and three A-CHESS service categories. In latent profile analyses, three A-CHESS system use patterns—inactive, passive, and active users—were found. Compared to the passive users (with the highest chance of the initial lapse), the active users (with the lowest chance of such behavior) participated more in online social activities, used more sessions, viewed more pages, and used A-CHESS longer. However, the chances of the initial lapse between A-CHESS user profiles were not statistically different. Implications of this finding were provided.

Introduction

In 2012, 7% of the U.S. population aged 12 or older were diagnosed with alcohol dependence or abuse.[2] One major challenge in current addiction treatment is to extend care beyond traditional in-patient treatment.[3] The emerging application of mobile communication and sensor technology in health care (called mHealth) has the potential to complement current treatment approaches in alcohol relapse prevention.[4–6] Evidence shows that mHealth is well accepted by the underserved populations with chronic diseases (including addiction).[7,8] Although mHealth is pervasive, highly accepted, and seemingly effective, less is known about how patients actually took advantage of it, and whether different mHealth use patterns may lead to different health outcomes.

Addiction-Comprehensive Health Enhancement Support System (A-CHESS) is a smartphone application developed to support patients with alcohol addiction after they leave residential care. A recent randomized controlled trial showed a significant reduction in the number of risky drinking days for patients who were given the access to A-CHESS.[1] A-CHESS offers patients the ubiquitous access to services designed to promote the three basic needs (i.e., autonomous motivation (AM), coping competence (CC), and social relatedness (RE)) outlined in the Self-Determination Theory (SDT).[7,9,10] For example, the alerts and recommendations in A-CHESS are intended to supplement the impaired cognitive functions of patients by helping them to adopt effective coping strategies when needed. A-CHESS can connect patients to the immediate support network including their addiction counselors, families, and peer patients. Motivational stories and messages from their counselors and peer patients may motivate patients to be on top of their own recovery. The continuous access to services provided in A-CHESS is not available in any existing addiction treatment program, and its use and impact on addiction outcomes is worth exploring.

A recent development of A-CHESS is a predictive feature of alcohol lapses. Using patient-reported recovery status in A-CHESS, such as the levels of urge and alcoholics anonymous (AA) meeting attendance, a Bayesian network model was developed to assess the risks of a lapse within a week of reporting.[11] The model successfully predicts more than 80 percent of the cases.[11] In this model, patients with recent lapse experiences were found to have a higher chance of subsequent lapses. In other words, the model can better identify potential lapsers based on whether they have lapsed recently. However, for those who did not lapse recently (i.e. the initial lapse cases), the prediction could be further explored and improved.

A-CHESS use patterns that occurred before initial alcohol lapses may inform the likelihood of such events and make early interventions possible. Studies have shown that coping activities may reduce the risks of initial lapse.[12] The use of A-CHESS can be considered as a coping behavior. The patterns of A-CHESS use before the initial lapse could potentially offer valuable information to improve initial lapse prediction and prevention. The purpose of this study is to explore the A-CHESS use patterns before the initial lapse reported by the patients who have just completed residential treatment and returned to their own community.

A-CHESS System Use

A-CHESS creates electronic log files containing patients' use of the system. Log file analyses provide rich information about how the technological systems work and how patients may gain benefits from using different components in the systems.[13] In order to go beyond the traditional log file analyses where only the amount of use (e.g., page views) is analyzed, a comprehensive use-measurement framework that contains different levels of system use measures (i.e., system entry, exposure, and engagement) may help to better understand the use patterns of a multifunctional and comprehensive application, like A-CHESS.[14]

In mass media research, system entry is closely related to selection, meaning that people intentionally choose to allocate their time and attention to certain mass media, in this case, A-CHESS. System entry means that users choose to turn on A-CHESS and can be operationalized as a successful login or session.[14] Just as a psychosocial and behavioral intervention received by alcohol addiction patients, A-CHESS system entry means that patients choose to attend (open) the treatment (the applications). Choosing to access the treatments may imply stronger motivation of alcohol addiction patients.[15] Mounting evidence shows that the attendance of treatment sessions, AA meetings, religious activities, or 12-Step group meetings is significantly related to improved abstinence outcomes.[16,17]

System exposure refers to how much information is perceived by the users, often operationalized to be the amount (the number of pages) or the degree (the amount of time) of the exposure. As patients browse through more content in A-CHESS, they may feel more informed, more supported, and more motivated to resist the temptation to lapse. Studies showed that patients who attend more treatment sessions are more likely to achieve better outcomes.[18,19]

System exposure focuses on "what" contents are perceived by patients, while system engagement focuses on the patients' interactions with the system. A-CHESS patients may not only passively receive information but also actively engage in various navigation strategies. They actively learn from and communicate with the other patients or counselors via the social networking tools. Most importantly, A-CHESS users may choose to engage in using the system for a sustained amount of time. Previous studies showed that expressing emotional support and empathy in an online environment was related to a reduction of concerns and improved quality of life.[20] Patients who used the information systems more continuously (i.e. longer over-time use) reported improved health competence, social support and active participation in health care.[21] Similarly, Moos and Moos (2007) found that patients with alcohol addiction who participated in AA meetings for a longer time period were more likely to be remitted at all four follow-ups[22]. The participation of social networks has also been found to be an important protective factor in the recovery journey of patients with addiction.[23]

Although system entry needs to occur before exposure or engagement can be reasonably measured, and exposure must occur for engagement to be meaningful, these three use measurement levels are not in a continuum.[14] Since the tools in A-CHESS offer different functions and contents that are designed to meet the three SDT needs, the combination of three levels of system use measurement with three SDT classified A-CHESS services may offer a more comprehensive view of A-CHESS use patterns (e.g., entry to relatedness services, exposure to coping competence services, and engagement with autonomy motivation services).

Latent Profile Analysis to Study System Use

A holistic approach is needed to study the effects of A-CHESS system use patterns. By considering multiple use measures simultaneously, we can better understand the impact of the system on patient outcomes. Latent class analysis (LCA) has been increasingly used as an exploratory approach to study the underlying patterns of complex, observed response variables in either dichotomized or continuous scales.[24] Compared to traditional clustering algorithm, such as k-mean, LCA is a model-based approach that offers cluster solutions that are supported by rigorous statistical tests and is based on a mixture of the underlying probability distribution, which makes the solution less arbitrary.[25] Latent profile analysis (LPA), a type of LCA in which all indicators are continuous, has been used in medical research to identify relevant and valid groups in skin cancer risks[26], youth risky behavior patterns[27], and alcohol dependence and abuse.[28] In a recent study of the system use patterns of a web-based eHealth intervention for cancer patients, LCA was proved to be a useful technique to identify subgroups of eHealth system users.[29] In the present study, because the use measures are continuous, LPA will be used to explore the underlying A-CHESS use patterns based on a comprehensive set of A-CHESS use measures.

In a recent review of various effective behavior interventions for addiction patients, researchers pointed out that the real challenge is to choose the most appropriate treatments for a given patient.[30] The same challenge was faced in the development of various services offered in A-CHESS. Exploring A-CHESS use patterns before the initial lapse may

offer important information about which patterns of system use matter in A-CHESS. Ultimately, the understanding of effective A-CHESS use patterns may help to design more effective mHealth interventions for addiction patients.

Methods

Participants

170 patients were randomized into the intervention group in a randomized trial.[7] Among them, 142 patients were included in this study because of the inclusion criteria during data cleaning (see section in Data preparation and analysis). The intervention group was given the access to A-CHESS; the control cases did not have access to A-CHESS and so are excluded from this analysis. The patients were recruited from two residential treatment organizations—one in the Midwest and the other in the Northeastern U.S.—from February 2010 to November 2011. They were at least 18 years old, met the criteria for DSM-IV[31] alcohol dependence when they entered treatment, and were able to provide two backup contacts for follow-up. Patients were excluded if they had a history of suicidality, a significant developmental or cognitive impairment that would limit the ability to use A-CHESS, or vision problems.

Procedures

The study was conducted according to the Declaration of Helsinki of 1975 and approved by the Institutional Review Board at the University of Wisconsin-Madison. Patients were recruited at each clinic by project coordinators before they were discharged. Written informed consent was obtained. Before leaving the facilities, patients received training on how to use A-CHESS and the smartphones from their counselors. On the day when they were discharged (i.e. the intervention date), they each received a smartphone (either Palm Pre or HTC Evo) with a pre-installed A-CHESS program. The 3G mobile broadband connection was paid up to 8 months after the intervention dates. The patients agreed to use A-CHESS. However, using A-CHESS is not required to stay on study. The system log data were sent to a secure server at University of Wisconsin-Madison. Details about the trial can be found elsewhere.[1]

Intervention—SDT-Based Services Provided in A-CHESS

A-CHESS services were designed to focus on one or more SDT needs.[10] Detailed information about different A-CHESS services has been reported elsewhere.[7,10,32] The following is a list of services targeting each SDT construct.

Services for promoting autonomous motivation. High-Risk Locator, Notifications, Recovery Motivation, Panic Button, Weekly Check-in, Daily Check-In, Sobriety Date Counter, Our Stories, and Recovery Podcasts.

Services for improving coping competence. Notifications, Panic Button, Discussions, Ask an Expert, News, Easing Distress, Instant Library, Recovery Information, Open Expert, FAQs, Weblinks, Tutorials, Our Stories, and Recovery Podcasts.

Services for building relatedness. Panic Button, Weekly Check-in, Daily Check-In, Discussions, Ask an Expert, Events and Meeting Planner, My Friends, My Messages, My Profile, My Team, and Team Feed.

Measures

Initial lapse and prediction relationship. The substance use item from the Weekly Check-in was used as the indicator of a patient's initial lapse status. The Weekly Check-in is a self-monitoring service in A-CHESS for patients to track their recovery progress.[11] Patients filled out an online questionnaire in the Weekly Check-in every 7 days in A-CHESS on smartphones. The status of their self-reported substance use behavior (i.e., drug and alcohol use) in the last 7 days was measured on a dichotomous scale (yes/no). Therefore, a lapse is defined to have occurred when a patient indicated that he/she used alcohol or took drugs in the last 7 days in their Weekly Check-in reports.[11] Patients may report lapses in multiple Weekly Check-in reports during the 8-month study period. The first reported lapse cases in the Weekly Check-in after patients left the treatment facilities were identified as the initial lapse cases.

The lapse status that patients reported in the Weekly Check-in was about their substance use in the last 7 days. If the time between two consecutive Weekly Check-ins was more than 14 days, the prediction was considered invalid because it was separated by too many days from the prior report.[11] Therefore, only a current Weekly Check-in with a subsequent Weekly Check-in within 14 days was considered an effective data point. If the next Weekly Check-in reported a lapse, it was taken as such; otherwise, it was considered a non-lapse. The use data that happened between the current Weekly Check-in and the previous Weekly Check-in were retrieved and used to develop measures of pre-lapse A-CHESS use (Figure 1).

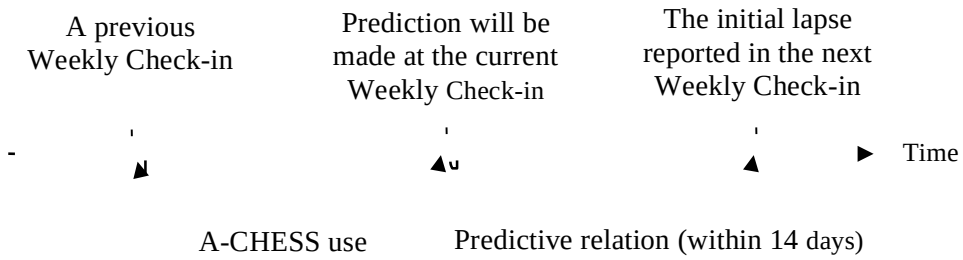

Figure 1. Initial lapse prediction conceptual diagram
Note: A-CHESS: Addiction-Comprehensive Health Enhancement Support System

Use measurements. A-CHESS was programmed to constantly record log files at the level of individual keystrokes or clicks of hyperlinks. The log files—with unique user identifiers and timestamps—can reveal precisely who requested what A-CHESS services and when. The log files can be used to establish activities in which the user was engaged (e.g., posting or reading) as well as the specific services that were requested (e.g., news or discussion group messages). From the log file data, A-CHESS use metrics were developed based on a combination of the SDT-focused A-CHESS service categories and the three levels of system use: entry, exposure, and engagement. SDT-based A-CHESS services were defined above. The operational meanings of the use measures are listed below.

Average daily sessions as system entry. The average number of daily sessions between the previous and current Weekly Check-in was calculated as the measurement for system entry. A new session is recorded when patients switched from using one service, such as discussion group, to another, such as easing distress. Four system entry measures were developed: Total entry (i.e. system entry measure of all A-CHESS services), AM entry (i.e. system entry measure of autonomous motivation services), CC entry (i.e. system entry measure of coping competence services), and RE entry (i.e. system entry measure of relatedness services).

Average daily pages viewed as system exposure. System exposure could be operationalized by pages viewed or time spent. Compared to those using computer-based applications, smartphone users were not restricted to a physical location, and therefore, could be more easily distracted by other tasks, like crossing the roads. This could cause time-based exposure measures to be overestimated. In addition, the contents in A-CHESS are often short and simple, and therefore may not require much time to achieve comprehension. Therefore, the duration of time between pages may not be the best measure in the context of a smartphone application. The amount of content (the number of pages viewed) may be a more useful and realistic measure of system exposure. The average number of daily pages viewed between the previous and current Weekly Check-in was calculated as the measure for system exposure. Four system exposure measures were developed: Total exposure (i.e. system exposure measure of all A-CHESS services), AM exposure (i.e. system exposure measure of autonomous motivation services), CC exposure (i.e. system exposure measure of coping competence services), and RE exposure (i.e. system exposure measure of relatedness services).

Percentage of days using A-CHESS as over-time system engagement. Over-time engagement has been used to describe the commitment and the continuous nature of system engagement in other studies.[14,21] In this study, the measure of over-time system engagement was operationalized by dividing the number of days a patient used A-CHESS by the total number of available days between the patients' previous and the current Weekly Check-in. The scale for this percentage measure is from 0% to 100%. Four over-time system engagement measures were developed: Total over-time engagement (i.e. over-time system engagement measure of all A-CHESS services), AM over-time engagement (i.e. over-time system engagement measure of autonomous motivation services), CC over-time engagement (i.e. over-time system engagement measure of coping competence services), and RE over-time engagement (i.e. over-time system engagement measure of relatedness services).

Average daily posting messages as social system engagement. The average number of daily messages posted or sent by patients between the last and the current Weekly Check-in was used to measure social system engagement. Because this measure describes the activity in online social services without a strong reference to SDT content categories, only one use measure was developed for social system engagement.

Data Preparation and Analysis

The use data retrieval was based on the submission date/time of the selected Weekly Check-in reports. Initial lapse cases were retrieved from the Weekly Check-in database as described in the process flow chart (Figure 2). In August 2011, a new intervention component was added to provide additional, automatic alerts sent out to both patients and counselors about patients' risk of upcoming lapses.[11] To avoid the impact of the new intervention on the predictive relationship studied here, four patients were excluded because all of their Weekly Check-in reports were submitted after this new intervention feature. Of the remaining patients, six did not have effective initial prediction data points: that is, a Weekly Check-in followed by a subsequent Weekly Check-in submitted within 14 days (Figure 1). Among 152 patients with effective prediction cases, 58 reported a lapse in at least one report, but 7 of them were excluded because their initial lapse was reported during their first Weekly Check-in—no prior Weekly Check-in can be used together as a prediction point. Because the 51 initial lapse cases occurred in different weeks of the 8-month study period, a matching process was performed to select compatible non-lapse cases. The process selected a number of non-lapse reports at a particular time point (e.g., 4th week after intervention) to match to the same proportion of lapse cases reported on the same week. Because all the initial lapse cases happened after the 2nd week of the intervention, 3 patients who only have non-lapse reports at the 2nd week were excluded as not matched non-lapse cases. The final dataset contains 51 lapse cases and 91 non-lapse cases.

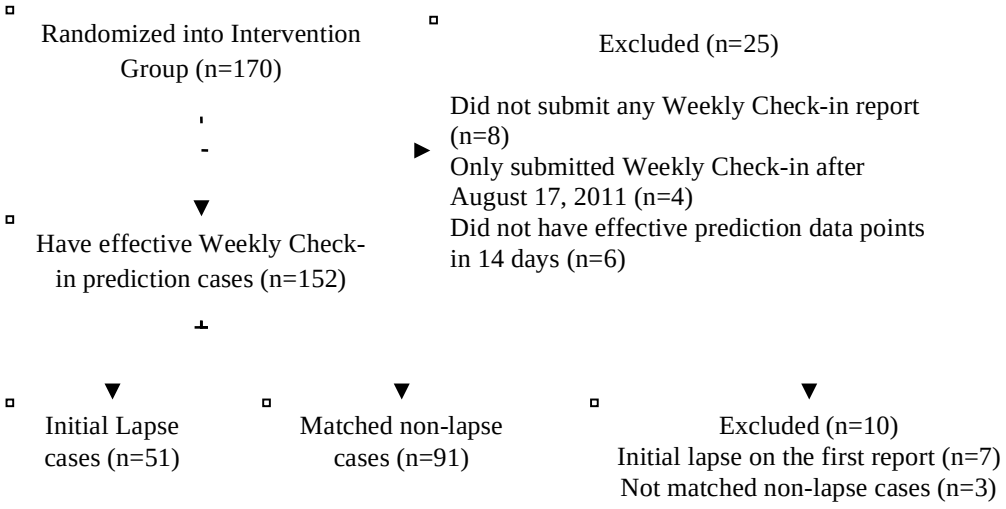

Figure 2. Initial lapse data process flow chart

After selecting these 142 cases (i.e. 51 lapse and 91 non-lapse cases), A-CHESS log data between reports (Figure 1) were retrieved. Usage measures were calculated for each case. Outliers (with a z-score over 3 or below -3) were recoded to the next most extreme values to minimize the impact of outliers.[33] A LPA was conducted to identify the underlying A-CHESS use patterns. For some variables with high proportion of extreme boundary values (e.g. 38% of non-users for coping competence services and 33% of patients had a 100% in total over-time engagement), a censored normal distribution was used in LPA using Mplus v7.11.[34,35]

This LPA identified the underlying use patterns (i.e. latent profiles) based on the comprehensive A-CHESS use measures. The number of latent profiles was increased until the most parsimonious model solution was found. The most parsimonious model was determined by minimizing Bayesian Information Criteria (BIC), statistically significant results in Lo-Mendell-Rubin likelihood ratio test (LMR-LRT), and entropy (over 0.9).[36] During each latent class modeling procedure, a three-step process was adopted to test the predictive relationship between latent profile groups and the distal outcome variable (i.e. the subsequently-reported initial lapse in the following Weekly Check-in). The three-step procedure can avoid the impact of the distal outcome variable on the latent profile groups when they are in the same model.[37] The three-step model, implemented in Mplus v7.11, was used to offer the pair-wise chi-square test of the probabilities of the initial lapse among the latent profiles.[37]

Results

142 patients (51 initial lapse cases or lapsers; and 91 non-lapse cases or non-lapsers), had a mean age of 37.93 years old (from 20 to 64), mostly Caucasians (82%) and mostly male (60.6%). About 40% of patients have received some college education or higher. Only 19% of patients are currently employed. About 60% of patients have abused drugs. Table 1 shows the descriptive statistics of demographic characteristics and A-CHESS use measures. Less than 4% outliers ($z > 3$) were found in all A-CHESS use measures except the Total, CC, and RE over-time engagement measures. The results of t-tests (for continuous variables) and chi-square tests (for categorical variables) showed that lapsers and non-lapses were not statistically different on most demographics and use measures. However, compared to non-lapsers, lapsers are more likely to be female (p=0.005) and currently unemployed (p=0.036).

Table 1. Descriptive statistics of patient characteristics and A-CHESS use

	Lapsers (n=51, 36%)	Non-lapsers (n=91, 64%)	p-value

	0.32(0.43)	0.27(0.43)	0.451

Abbreviations: A-CHESS: Addiction-Comprehensive Health Enhancement Support System; AM: Autonomous motivation; CC: Coping competence; RE: Relatedness

A latent profile model was developed and estimated. The model contains all use measures outlined in the Measures section. Model fits indices based on different numbers of profile solutions were listed in Table 2. Among these

indices, BIC keeps decreasing when models become more complicated, and all models have good delineation of profiles with high entropy over 0.9. However, by examining LMR test result, the 3-profile solution was selected because the LMR test showed that the four-level model does not significantly improve the model fit (p=0.3849).

Table 2. Fit statistics of latent profile models

Full model				Decision
Number of Profiles	BIC	Entropy	LMR(p)	
2	9286	0.971	0.0452	
3	8943	0.968	0.0244	Selected
4	8760	0.976	0.3849	

Abbreviations: BIC: Bayesian Information Criteria, LMR: Lo-Mendell-Rubin likelihood ratio test.

In Table 3, model estimated profile means were listed to provide an overview of the latent profiles' characteristics. Based on the profile means of the use measures, three profiles can be named as inactive (35.9%), passive (49.3%), and active users (14.8%). The inactive users have the lowest A-CHESS use with lower than one service session per day, and about 40% over-time system engagement. The passive users have modest A-CHESS use, but their use in several over-time system engagement measures (except for CC over-time engagement) approached to the active users. Compared to the passive users, the active users have used more sessions, viewed more pages, and used A-CHESS longer especially in coping competence and relatedness services. The active users also more actively posted messages (almost one message a day) via online discussion groups or personal messages, than the passive users (about one message every three days). The active users have the lowest percentage of initial lapsers (28.6%) while the passive users have the highest chance (40.2%) for an initial lapse. However, the probabilities of the initial lapse between these three groups were not statistically different (p=0.315 to 0.691) at the present study.

Table 3. Model details

Profiles		Inactive Users	Passive Users	Active Users
% of profile membership counts[1]		35.9	49.3	14.8
% of the initial lapse		33.3	40.2	28.6
Model estimated profile means	System Entry (Average daily sessions)			
	Total Entry	0.82	3.98	13.14
	CC Entry	0.21	0.65	3.00
	RE Entry	0.39	1.83	5.09
	AM Entry	0.14	0.32	0.49
	System exposure (Average daily pages viewed)			
	Total exposure	4.22	15.26	36.70
	CC exposure	0.37	1.45	6.49
	RE exposure	3.01	9.70	25.51
	AM exposure	1.26	2.08	2.39
	Over-time system engagement (% of days using A-CHESS)			
	Total over-time engagement	41.90	90.54	95.46
	CC over-time engagement	6.17	24.12	68.22
	RE over-time engagement	33.57	81.71	93.58
	AM over-time engagement	23.87	35.37	43.72
	Social system engagement (Average daily posting messages)			
	Total	0.05	0.30	0.89

Note: 1. The percentages of user counts in profiles were based on the most likely latent profile membership. 2. Abbreviations: A-CHESS: Addiction-Comprehensive Health Enhancement Support System; AM: Autonomous motivation; CC: Coping competence; RE: Relatedness

Discussion

The purpose of this study is to explore the underlying use patterns of a mobile health application, A-CHESS, before the initial lapse after a period of inpatient alcohol detoxification. A-CHESS use measures were developed based on three-level system use framework (i.e., system entry, exposure, and engagement), as well as three SDT service

categories (i.e., autonomous motivation, coping competence, and relatedness services). In LPA, three profiles and their unique use patterns were found (Table 3). The inactive users really did not use A-CHESS much. Although the inactive users turned on A-CHESS on average in 4 days out of a 10-day period, they utilized very few (like one or two pages) coping competence and autonomous motivation services. In this case, they may just read the "daily thought" (i.e. an encouragement message sent out each day) or use the Weekly or Daily Check-in, which A-CHESS showed a reminder message on the phone screen. Compared to the inactive users, the passive users used the "social network (relatedness)" services more frequently. However, this use pattern may also be due to the "daily thoughts" message sent to them daily. The passive users did not post or read as many messages as the active users. Therefore, the inactive users did not use A-CHESS regularly even with the daily alerts. The passive users turned on A-CHESS (probably because of the daily prompts) but were not very engaged in using A-CHESS. The active users truly used A-CHESS regularly and actively. The passive users have the highest probability (40.2%) of the initial lapse in the following week while the active users have the lowest probability (28.6%) of such events. However, the probabilities of the initial lapse between these three user profiles were not different.

The non-statistically different likelihoods of the initial lapse between A-CHESS use profiles do not allow for further inferential conclusion to be drawn. However, the different A-CHESS use patterns and their relative chances of lapses—seemingly matching to the literature—showed the potential to explore further and worth mentioning. Compared to the passive users with the highest likelihood of the initial lapse, the active users who have the lowest likelihood of the initial lapse used more service sessions, viewed much more content about coping competence, and especially actively reached out to others by posting or sending messages. This observation is similar to what was found in the addiction literature where patients who participated more treatment sessions, improved their coping skills, and built stronger support network usually experienced better recovery outcomes.[22,23,38,39] Therefore, the active users' A-CHESS use patterns may be worth promoting, especially for those who consumed fewer coping competence services and less actively participated online social network. The inactive users may be a mix of those who have smooth recovery and did not feel the need of using A-CHESS, and those who really needed helps but just did not want to use A-CHESS for some reasons. Therefore, their chance of the initial lapse (33.3%) fell in between the other two user groups.

This study has several strengths in both system science and addiction recovery research. The analysis of system use behavior in this study was based on the actual log files, which are the objective observation of each activity that patients have with the intervention system, A-CHESS. Therefore, the results in this study have provided a different perspective of user behaviors other than the self-reported system use. Future studies that examine both the log files and the self-reported system use may offer a more complete picture of user behaviors. In addition, a comprehensive set of A-CHESS use measures were developed and analyzed together, which offered rich information about the different A-CHESS use patterns before the initial lapse. The LPA results, although non-conclusive, seemingly match well with the existing addiction literature regarding treatment effects on the alcohol lapse. The findings from this study may benefit to the design of A-CHESS-like technological interventions. The method used to study the system use patterns may serve as an example for researchers who develop and test new mHealth interventions.

Several limitations were related to the data used in this study. First, the data used in this analysis were based on patients' Weekly Check-in. If patients did not fill out Weekly Check-in in a way as described in the Methods section, their data would not be included in the analyses. Patients who did not fill out Weekly Check-in may have some valid and non-ignorable reasons that could be related to their substance use status. For example, some patients who drank might not want to disclose their drinking status in A-CHESS but would tell their counselors at a different setting. This kind of non-random missingness may limit the generalizability of the results. The latent use profiles found in this study may not be applied to all patients but only to those who would use A-CHESS and Weekly Check-in. Besides, the overlapped SDT categories may lead to potentially high correlations between the A-CHESS use measure indicators. A more complex model with a higher number of profiles may be needed in order to fit a complex correlation structure in our data. However, the relatively small sample size in this study precluded the construction of a more complex model and may not offer enough power to detect the group differences. Besides, patients from two treatment agencies may not be representative to the general alcohol addiction population. Therefore, future studies should acquire more participants from more sites in order to confirm and further understand the results of the present study. According to a recent PEW research report, adult smartphone owners in the U.S.A. increased from 30% to 50% in early 2013.[40] As mobile communication technology becomes more common, it is more likely to run population-based trial on A-CHESS or similar systems at a lower cost.

Patients who suffer from alcohol addiction need continuous support in order to recover from their addiction. In this case, ubiquitous mobile technology, like a smartphone, can be useful to deliver such interventions. This study

offered an understanding of the patients' A-CHESS system use patterns, and how these patterns were related to the chances of patients' initial lapse after the residential detoxification programs. Future research in this area to test and extend these findings is needed in order to develop and refine effective mHealth interventions for addiction patients.

Disclosure and Acknowledgement

The author reports on a part of his dissertation and his involvement in a clinical trial testing A-CHESS. The reason that the author is listed as the only author in this paper is because the author has the solo responsibility to the integrity and quality of his dissertation. The author appreciates the support from his mentor, Dr. David H. Gustafson and all the committee members, as well as the dedicated and talented project team behind this trial.

Online Deviation Detection for Medical Processes

Stefan C. Christov, George S. Avrunin, Lori A. Clarke
School of Computer Science, University of Massachusetts Amherst, MA

Abstract

Human errors are a major concern in many medical processes. To help address this problem, we are investigating an approach for automatically detecting when performers of a medical process deviate from the acceptable ways of performing that process as specified by a detailed process model. Such deviations could represent errors and, thus, detecting and reporting deviations as they occur could help catch errors before harm is done. In this paper, we identify important issues related to the feasibility of the proposed approach and empirically evaluate the approach for two medical procedures, chemotherapy and blood transfusion. For the evaluation, we use the process models to generate sample process executions that we then seed with synthetic errors. The process models describe the coordination of activities of different process performers in normal, as well as in exceptional situations. The evaluation results suggest that the proposed approach could be applied in clinical settings to help catch errors before harm is done.

1 Introduction

Human errors are a major concern in many medical processes. In 1998, an Institute of Medicine (IOM) report estimated that preventable medical errors cause the death of 98,000 people each year in the U.S.[1] More than a decade later, a 2009 U.S. National Research Council report[2] indicated that the problem with errors still persists and that "it is widely recognized that today's health care … suffers substantially as a result of medical errors." A recent study[3] from 2013 reported an even higher estimate of deaths per year, between 210,000 and 400,000, in the U.S. due to medical errors.

To help address this problem, we are investigating an approach for automatically detecting when performers of a medical process deviate from the acceptable ways of performing that process. Such deviations could represent *planning errors*[*] and, thus, detecting and reporting deviations as they occur (i.e., online) could help catch such errors before something bad happens. Here we use the word *process* to refer to the coordination of activities to accomplish a task or a goal, where the activities may be performed by humans, devices, or software systems. We refer to the *execution* of the process as the sequence of steps that are actually performed to accomplish the task or the goal. Our process models capture the process executions typically described in clinical guidelines or protocols, but also include additional detail, such as how guidelines should be executed when exceptional situations arise and customization that might occur for a particular clinical setting.

Detecting deviations could be challenging, however, because of the complexity of medical processes. Medical processes often contain multiple decision points that might require expert judgment, multiple possible exceptional situations that might require special handling, and multiple subprocesses that might be performed concurrently by different medical professionals. This typically results in a very large set of acceptable executions of a medical process. The proposed deviation detection approach uses techniques from software engineering for constructing a compact model describing all acceptable executions of a process. The large number of possible executions, however, combined with the fact that the process execution that human process performers intend to follow is often unknown (and could change as the process is being performed), makes online deviation detection difficult.

The proposed deviation detection approach relies on monitoring an executing process to determine whether the way the process is being performed deviates from the way it should be performed as specified by the process model. In particular, the approach aims to detect the manifestation of errors, i.e., *error phenotypes*[18], in a sequence of performed activities. Recent developments in healthcare and informatics should enable monitoring and recognizing many of the activities performed in real time, that is, as the process is being executed. For example, electronic medical records are being introduced in more hospitals and data entries in such records could be used to infer what activities are being/have been performed. Medical scribes are increasingly being used in medical processes to document the executing process[4] and thus could capture the activities as they are being performed. Computer vision techniques could also be utilized to recognize performed activities in a live video stream from cameras installed in a hospital room.

[*] A *planning error*, as defined by the IOM report[1], is "the use of a wrong plan to achieve an aim". Examples of planning errors are omitting an activity that should have been done (error of omission) or performing an activity that should not have been done (error of commission).

Even if we assume a perfect mechanism for monitoring an executing process, however, there are important issues related to the feasibility of the proposed deviation detection approach that need to be explored before the approach could be deployed in a clinical setting. One of these issues is potential harm due to *delayed deviation detection*. Delayed deviation detection arises when process performers deviate from the acceptable executions of a process, but this deviation cannot be detected until additional process activities are performed. Since the intent of process performers is often unknown to the monitoring system and some decisions at branch points in a process could depend on subjective (and potentially error-prone) human judgment based on experience and domain expertise, a monitoring system might not know which branch(es) should be taken in a given execution of the process. For example, suppose that at a branch point a human intends to perform one branch, but, due to distraction or fatigue, makes a commission error by first performing steps from another branch before performing the steps from the intended branch. In that case, a monitoring system will not be able to detect the commission error until the human performs the first step of the intended branch, or possibly until even later, if the two branches have common steps.

Ideally, we would like to detect deviations before harm is done as a result of these deviations, but the presence of detection delay could prevent achieving this goal in some situations. In this paper, we investigate how frequently delayed deviation detection could arise in medical processes, how often harm could occur because of the delay, and what the causes for detection delay could be. Harm could also occur as a result of a deviation even when there is no deviation detection delay, and we investigate this issue as well. We also investigate the performance of the deviation detection approach in terms of computation time. If the computation time to detect a deviation is too long, harm could be done before process performers are notified of the deviation.

Our initial evaluation of the deviation detection approach has been promising. Delayed deviation detection rarely arose in the medical processes we studied and when it did arise, no harm to the patient could occur as a result of the delay. The running time of the deviation detector is low relative to the human speed of performing process activities, suggesting that it could be used for online deviation detection.

Section 2 discusses related work, the proposed deviation detection approach, and some issues associated with that approach. The experimental methodology for evaluating the approach with respect to these issues is presented in section 3. The results are presented in section 4 and discussed in section 5. Section 6 summarizes the paper and describes future work.

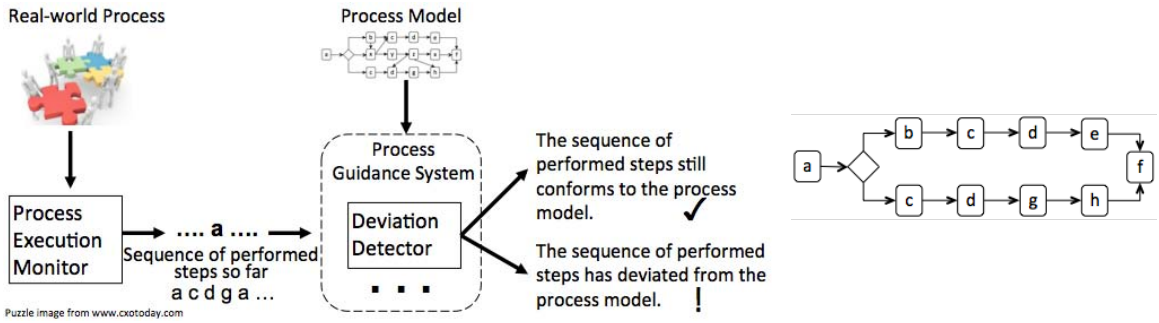
2 Background

2.1 Related Work

There are several approaches that aim to reduce the number of medical errors by encouraging conformance with some specification of the acceptable ways to perform a process (e.g., process aids such as checklists[5,6] and care sets[7]). Such process aids, however, tend to specify only the major steps during normal flow, omitting important details such as exceptional scenarios and concurrent process execution[8,9]. Such process aids often add to the workload of already heavily-burdened medical professionals. The use of checklists, for example, often requires medical professionals to check what needs to be done, to remember what steps they completed, and to determine the appropriate checklist to use in a given context.

To remove some of the burdens that process aids, such as checklists, place on medical professionals, there have been attempts to create systems that automatically check the compliance of an executing process with a specification of that process[11]. To support such systems, various medical guideline modeling languages have been developed[10]. Subsequent work has utilized formally specified medical guidelines to drive careflow management systems. For example, Fitzgerald et al. designed and deployed a careflow management system in a trauma center to guide medical professionals during the first 30 minutes of trauma resuscitation[11]. This system increased compliance with the modeled medical protocol and reduced error rates, but the model did not support complex process behaviors, such as concurrency and exception handling. The framework we are proposing, including the work reported in this paper, is intended to go beyond these limitations.

In prior work, we constructed detailed models of several medical processes[8,9,12] in consultation with medical professionals. We also constructed a framework and a set of tools for analyzing such models to detect various safety problems and evaluate proposed changes[12]. Although building and analyzing such detailed models takes considerable care and time, this work resulted in an improved understanding of the processes and the detection of several errors and vulnerabilities, leading to nearly 70% reduction in the number of errors reaching the patient in one of our studies[13].



(a) Process Monitoring and Guidance Framework.

(b) An Example Control Flow Graph

Figure 1: The Process Monitoring and Guidance Framework and an example of a simple CFG.

We are now beginning to examine the potential for using such models, validated by the analyses, for the monitoring and guidance of executing processes.

2.2 Deviation Detection Approach

The proposed deviation detection approach is a component of a framework we are developing for process monitoring and guidance. This framework also supports other process guidance aspects, such as pro-actively informing process performers of pending activities depending on how the execution of the process develops and providing capabilities for inspecting process execution history.

In this paper, we focus on the deviation detection aspect of the framework. Figure 1(a) shows the relevant components of the framework. As a process is being performed, the *Process Execution Monitor* captures events associated with the performed steps and incrementally creates the *sequence of performed step events*. We use the term *step* to refer to an activity of interest performed as part of a process by humans, software or hardware devices. For this paper, we assume that the sequence of performed step events is accurate, i.e., the sequence contains events for all steps of interest that have been performed, these events are in the order in which the actual steps were performed, and events that are not of interest have been accurately removed[†]. The precise way that the Process Monitor captures events is beyond the scope of this paper.

Every time the *Deviation Detector* receives a step event from the Process Execution Monitor, it checks if the corresponding sequence of steps performed so far is one of the acceptable sequences as specified by the *Process Model*. If it is not, a deviation is detected and process performers are warned that a potential error might have occurred.

Process Model. The process model captures the acceptable ways to perform the corresponding process. This includes the nominal ways, but also how the process should be performed when various exceptional situations arise. The model can also capture different ways to perform the process depending on the level of expertise of process performers.

Eliciting information from domain experts to create such process models and translating the elicited information into an actual model are known to be difficult and time consuming. In our work, we have used several process elicitation methods, such as observations, structured, and unstructured interviews[13]. After creating process models based on the elicited information, we have used several formal analysis techniques to validate these models[12]. Regardless of how extensive the process elicitation and model validation efforts are, however, it is likely that process models will still contain some inaccuracies. Furthermore, process performers might execute a process in innovative and yet acceptable ways that are not captured in the process model. In practice, we expect process models to be continually updated as defects in the models are uncovered and/or as the modeled processes change.

In our experience, to support the complexity of medical processes, the process model needs to be written in a notation with rich and well-defined semantics. Specifically, such a notation should provide support for modeling human choice, exception handling, concurrency, and synchronization. For our work, we have chosen the Little-JIL[14] process modeling language, because it satisfies these requirements and because we have found that the Little-JIL's compact visual notation has facilitated communication with the medical professionals who have been helping us create

[†]To simplify the discussion, hereafter we shall refer to the sequence of step events associated with the sequence of actual performed steps as the sequence of performed steps.

and validate the models of the relatively large and non-trivial processes on which we have been working (two of these processes are briefly described in section 3.1). The proposed deviation detection approach, however, is independent of the process modeling language; it can be used with any language that has well-defined semantics that are also sufficiently rich to capture complex real-world processes. For the purposes of deviation detection, a Little-JIL model is translated into a typical control flow graph (CFG) representation of the possible step execution orderings associated with a process model, so in this paper only a simple control flow graph representation is shown.

Deviation Detector. The Deviation Detector traverses the CFG representation in a breadth-first way to determine whether the sequence of performed steps so far is a legal sequence of steps through the graph. For efficiency, this traversal is done incrementally, maintaining a frontier of possible nodes in the graph that could correspond to the last performed step. When this frontier becomes empty, i.e., when there is no path through the graph that corresponds to the sequence of performed steps, a deviation is detected.

2.3 Example of Applying the Deviation Detection Approach to a Medical Process

Consider the process of transfusing a unit of blood to a patient. This process usually starts after a nurse receives a physician's order to perform a transfusion. The nurse then needs to check if the patient's blood type and screen are known and, if they are not, obtains a blood sample from the patient and sends it to the lab for analysis. Once the type and screen are known, the nurse can request the appropriate blood product from the blood bank and pick it up when it becomes available. To administer a single unit of blood product, the nurse needs to provide some documentation and perform a series of checks to ensure that the right patient receives the right blood product at the right time. During the transfusion, the nurse needs to periodically check for complications (such as a transfusion reaction) and, if any arise, handle them appropriately. Once the transfusion is done, the nurse needs to evaluate the patient, create final documentation, and dispose of the infusion materials.

Most of the activities in the blood transfusion process consist of a fair number of subactivities that can occur in different orders and potentially different number of times. Problems could arise while performing many of these activities, making the blood transfusion process challenging to perform correctly and potentially error-prone[8].

A common error reported in the medical literature, and one that can cause severe harm to patients, is not fully following the procedure for verifying the patient's identity[8] while performing the series of checks before beginning the infusion. A possible instance of this error is omitting to verify that the patient is wearing the correct ID band. Consider the situation where in a busy emergency department patient X is wearing the incorrect ID band—that of patient Y. Perhaps a registration clerk had to place ID bands on several patients and inadvertently switched the ID bands. Suppose that patient Y is the one for whom a blood transfusion was ordered. Since patient X is wearing patient Y's ID band, if the nurse does not verify patient X's ID band prior to infusing the blood, patient X might receive the blood ordered for patient Y. Note that the nurse might still successfully perform other checks, such as the blood product checks, since they are done against the ID band and not against the patient's real identity.

Potential harm as a result of this error might be avoided if the nurse is warned that the process is being performed incorrectly before the infusion is started. The deviation detector could achieve this is by comparing the sequence of steps the nurse has performed against a model of the process. The sequence of steps that omits the step *verify that the patient is wearing the correct ID band* would not be a legal sequence through the process model and the deviation detector could establish that. Informing the nurse about such a deviation might help the nurse recover from the error before harm is done (i.e., infusing blood into the wrong patient).

2.4 Issues

Delayed Deviation Detection and Potential Harm Due to Delay. As discussed earlier, delayed deviation detection is an important issue to consider as it might constitute a significant threat to the usefulness of the proposed deviation detection approach, depending on how often delayed deviation detection arises and the severity of the consequences from the delay. For a concrete illustration of delayed deviation detection, consider the example control flow graph in Figure 1(b), assumed to have been created from a process model. In this CFG, nodes represent process steps and are labeled with letters. There is an edge from one node to another, if the step the first node represents can be immediately followed by the step the second node represents in the modeled process. The diamond node represents a branch point. When no branch conditions are modeled, such as when a medical professional needs to make a decision based on personal judgment and experience, the deviation detector cannot determine which branch should be taken in a particular process execution and must consider all options.

The two legal sequences of steps allowed by the CFG in Figure 1(b) are *abcdef* and *acdghf*. Suppose that during a particular execution of the process, the performers planned to carry out the sequence *abcdef*, but forgot to perform step *b*. In this situation, the deviation occurs when *b* is omitted, but it cannot be detected until *e* is performed, because *acd* is a valid sequence through the model. In this situation, we say that there is a detection delay of 2 (we measure the delay in terms of performed steps between the error—the omission of step *b*—and the step when the deviation is detected—step *e*). If the two branches in Figure 1(b) had a longer sequence of identical substeps (in this case this sequence is *cd*), the deviation detection delay could be even longer. In principle, the delay can be arbitrarily long and serious harm could potentially result from not detecting a deviation at the time when an error is made.

In this work, we explore the following research questions related to delayed deviation detection: How often do deviation detection delays occur in complex medical processes? How long are deviation detection delays? How harmful are deviation detection delays? What causes deviation detection delays and can they be reduced or avoided?

These questions could potentially be analytically explored by statically analyzing a set of process models. We have not been able to develop a reasonable static approach, however, that can handle multiple kinds of planning errors effectively (e.g., single-step omission, single-step commission, single-step substitution, omission of n consecutive steps, …, omission of n not necessarily consecutive steps, …, single subprocess omission, …, multiple subprocess omission, etc.). Thus, as a first step in exploring the above questions, we chose an experimental approach that applies the deviation detector to synthetically generated erroneous executions from realistic models of two medical processes.

Potential Harm When Deviations Are Detected without Delay. It is sometimes possible that deviations are detected immediately as an error is made (there is no detection delay), but harm could potentially still occur as a result of the deviations. For example, in the blood transfusion process discussed above, one of the checks that needs to be performed before infusing the blood is to ensure that the blood product has not expired. Suppose that the process model allows this check to occur immediately before infusing the blood. If the nurse forgets to check that the blood product has not expired, the deviation will be detected when the nurse starts the infusion. Even though there is no detection delay, harm could still occur as the patient might receive expired blood. This is an example of a vulnerability in the process model or in the process itself (assuming the model is accurate) with respect to the proposed deviation detection approach—a deviation cannot be detected until the potentially harmful step is already started.

In this work, we explore the following research questions related to the above issue: How often do situations arise where harm could occur even when deviations are detected without delay? What can be done to reduce or avoid such situations?

Running Time of the Deviation Detector. It is important that the deviation detector does not take too long to compute whether a deviation has occurred after a new step is added to the sequence of performed steps. Otherwise, if a deviation occurs, the warning about that deviation might get issued after harm was already done as a result of the deviation. We explore the following research question related to the performance of the deviation detector: What is the running time of the deviation detector when applied to realistic medical processes?

3 Methods

To perform an initial evaluation of the proposed deviation detection approach with respect to the above issues, we applied it to models of two medical processes—chemotherapy and blood transfusion. We generated sequences of performed steps from these models and then mutated the sequences to represent process executions with simple errors. Our evaluation approach is based on *mutation testing*[16], a common software engineering technique where a computer program is systematically mutated (usually by making a predefined set of simple changes to the source code) to evaluate software testing and analysis approaches.

3.1 Process models

The chemotherapy process model we used was elicited from medical professionals participating in an outpatient chemotherapy ordering and administration process in a regional cancer center in Western Massachusetts. At the time of writing this paper, the chemotherapy process model covers multiple phases of the chemotherapy process, including diagnosing the patient and ordering chemotherapy; thorough review of the treatment plan and medication orders by a medical assistant, a nurse, and a pharmacist; conducting an informational/teaching session with the patient and obtaining informed consent form; preparing chemotherapy drugs, performed by a pharmacist and pharmacy technicians; assessing the patient and administering the drugs, performed by a clinical nurse[13].

The blood transfusion process model is based on a standard blood transfusion checklist from the medical literature[5] and includes additional information about exceptional situations that might arise during the process and their handling. This model is part of a blood transfusion benchmark[15] that we developed with a nursing faculty member working on patient safety[8]. The model covers the process activities starting from receiving a physician order for transfusion to infusing the blood into the patient and performing subsequent follow-through checks. It specifies multiple phases of the process, including verifying that the patient blood type and screen are available (and if they are not, performing the subprocess of obtaining and labeling a blood specimen); ordering and obtaining a blood product from the blood bank; performing various verifications on the patient and on the blood product before starting the transfusion; monitoring the patient during the transfusion and appropriately reacting if a transfusion reaction is suspected.

The chemotherapy and blood transfusion process models are of significant size and complexity. The chemotherapy process model includes 283 steps performed by human process performers and specifies 59 exception handling situations[‡]. The corresponding low-level CFG representation has 2,358 nodes and 701,887 edges. The blood transfusion process model includes 102 steps, including 63 exception handling situations, and the corresponding CFG representation has 97,237 nodes and 242,442,845 edges. Even though the blood transfusion model has fewer steps than the chemotherapy model, the exception handling behavior in the blood transfusion process is more complex, requiring a large number of low-level CFG nodes and edges.

3.2 Sequences with synthetic errors

To evaluate the deviation detection approach, we applied it to step sequences containing typical planning errors. Although there is no standardized taxonomy of human errors[1,17], two error kinds appear in the intersection of most of the proposed planning error taxonomies[1,3,18]—omission and commission errors. An omission error occurs when one or more steps are not performed; a commission error occurs when one or more wrong step(s) are performed.

In our initial evaluation of the deviation detection approach, we focused on several kinds of planning errors that involve a single step and on the error of omission of a single subprocess. This decision was based on the errors available from a study of common errors in the blood transfusion process[8] and from conversations with blood transfusion and chemotherapy domain experts.

Single-Step Errors. From each of the two process models, we generated 50 sequences of steps by performing random walks through the process model. To represent "nominal-path" process executions, we also generated 50 sequences from each of the models but disallowed exceptional situations. Thus, we created 100 legal sequences for each process. Statistics about the lengths of the generated sequences are shown in Figure 2.

Each generated sequences was then mutated to represent a process execution in which the process performers deviated from the acceptable ways to perform the process. The applied mutations were deletion, insertion, and substitution of a single step at almost[§] every position of each sequence. A mutated sequence is called a *mutant*.

Subprocess Errors. Based on common blood transfusion and chemotherapy errors reported in the medical literature and on our interaction with domain experts involved in these processes, we identified 5 blood transfusion and 5 chemotherapy subprocesses deemed most likely to be omitted. The selected blood transfusion subprocesses were: (1) *ensure correct patient is present* (performed by a nurse before notifying the blood bank to prepare the blood to prevent the possibility the blood product to expire because the patient is not available for transfusion or the wrong patient is in the room); (2) *verify patient ID band* and (3) *verify blood product information* (part of the bedside checks performed by the nurse before beginning the infusion); (4) *assess patient* and (5) *evaluate patient clinically* (part of the clinical evaluation prior to the infusion, performed again by the nurse). The selected chemotherapy subprocesses were: (1) *record height and weight* (performed during patient registration by a clerk); (2) *confirm all necessary information is present* (part of the consultation and assessment, performed by an oncologist before creating the treatment plan and chemotherapy orders); (3) *confirm pretesting has been done* and (4) *confirm existence and not staleness of height/weight data* (part of the treatment plan and orders verifications performed by a Practice Registered Nurse (RN)); (5) *obtain patient informed consent* (performed by a Nurse Practitioner or a Clinic Nurse prior to chemotherapy administration).

For each identified subprocess, we generated 50 sequences from the corresponding process model, such that these sequences contain the subprocess. We then mutated each generated sequence by deleting all steps pertaining to the specific subprocess selected to be omitted. The deviation detection approach was applied to each mutant and various statistics were collected.

[‡]An exception handling situation usually involves multiple steps to deal with the exception. A step (e.g., *assess patient*), can be part of different subprocesses and be involved in different nominal and exceptional situations (e.g., patient develops an allergic reaction).

[§]There were a small number of cases, such as deleting the last step from a legal sequence, where the resulting mutated sequence did not correspond to a sequence with an error. Such cases were excluded from our analysis.

	Process definition	Blood transfusion process						
Set-up	Original traces	50 random			50 random, no exceptions			50 random sequences for each of 5 subprocesses
	Avg. trace length (number of steps)	21.52			70.62			70.54
	Min. trace length (number of steps)	4			69			68
	Max. trace length (number of steps)	114			73			73
	Mutation kind	Exp. 1: Deletion at every position (except last)	Exp. 2: Insertion before every position	Exp. 3: Substitution at every position	Exp. 4: Deletion at every position (except last)	Exp. 5: Insertion before every position	Exp. 6: Substitution at every position	Exp. 7: Deletion of all steps belonging to subprocess of interest
Results	Number of mutants	1026	1076	1076	3481	3531	3531	250
	Number of mutants where deviation is detected after the mutation index	0 (0.00%) [27] *	6 (0.56%) [1] ♮	5 (0.47%) [1] ♭	6 (0.17%) [294] *	25 (0.7%) [7] ♮	19 (0.54%) [1] ♭	0 (0.00%) [23] *
	Avg. deviation detection delay (number of steps), for mutants with detection delay	0.00	1.00	1.00	1.00	1.08	1.00	0.00
	Min. deviation detection delay (number of steps), for mutants with detection delay	0	1	1	1	1	1	0
	Max. deviation detection delay (number of steps), for mutants with detection delay	0	1	1	1	2	1	0
	Number of mutants for which delay could be "potentially harmful"	0	0	0	0	0	0	0
	Number of mutants without deviation detection delay for which harm could potentially occur due to the deviation	1 (0.01%)	24 (2.2%)	35 (3.3%)	50 (1.4%)	96 (2.72%)	90 (2.52%)	50 (20.00%)
	Avg. time per mutant (sec.)	5.98	5.88	5.74	13.01	13.12	13.09	11.17
	Avg. time per step (sec.)	0.28	0.27	0.27	0.18	0.19	0.19	0.16

* Number of mutants for which delay was due to a deletion in a shuffle region and deviation was detected right after the shuffle region.
♮ Number of mutants for which the delay was due to insertion of a step from a shuffle region in the model before the step has occurred in the corresponding shuffle region in the original sequence.
♭ Number of mutants for which delay was due to subbing in a step from a shuffle region in the model before the step has occurred in the corresponding shuffle region in the original sequence.
For the mutants in square brackets we used the "minimum interpretation" for the deviation detection delay (see the Discussion section for more detail).

Figure 2: Applying the deviation detection approach to the blood transfusion process model. The results for the chemotherapy process model are available at http://laser.cs.umass.edu/deviation-detection/amia2014.html.

4 Results

Figure 2 shows the results of applying the deviation detection approach to the blood transfusion process. Due to lack of space, we do not include the results table for the chemotherapy process, but make it available at http://laser.cs.umass.edu/deviation-detection/amia2014.html. The results from both processes were similar and are discussed in the next section. A deviation detection *delay* is defined as the number of steps between the *mutation index* (the index in the sequence of steps where the mutation was done for single-step errors or the index of the first mutation for subprocess errors) and the index where that sequence was recognized as not being a sequence from the process model.

5 Discussion

Delayed Deviation Detection and Potential Harm Due to Delay. Delayed deviation detection occurred infrequently—in less than 1% of the mutants from all experiments. We analyzed each mutated sequence with deviation detection delay by tracing that sequence through the corresponding process model to determine what structure(s) in that model caused the delay. The main cause for the delay was branching in the process models due to exception handling or optional steps/subprocesses. For example, suppose a process can be performed by executing step sequence *abcd*, when there are no exceptional situations. If an exceptional situation arises while performing *b*, however, then the sequence of steps *xyz* should be performed to address this situation before continuing with steps *c* and *d*, resulting in sequence *abxyzcd*. If the sequence *abcd* is mutated by inserting step *x* after step *b*, the deviation cannot be detected until step *c* is performed (which is one step after the mutation index) because *abx* is a prefix of valid sequence through the process model.

Another reason for detecting deviations after the mutation index were *shuffled* steps, which are steps that should be done sequentially but are allowed to occur in any order. For example, suppose that a process is performed by doing step *a*, followed by steps *b*, *c*, and *d* in any order, and then step *e*. Thus, if the step sequence *abcde* is mutated by deleting step *b*, a deviation will not get detected until step *e* is performed because *acd* is a prefix of a valid sequence through the process model. This results in a deviation detection delay of 2, using the measure of delay previously described.

Shuffled steps are different from other branch points in a process where there is more than one step to perform next, because any of the shuffled steps are acceptable to be performed next. Since shuffled steps are common in the processes we studied, we decided that deviation detection delays due to shuffled steps should be measured differently to avoid distorting the results. For example, if a mutation deletes one of several shuffled steps in a sequence of steps, we measure the delay as the number of steps between the last shuffled step in the sequence and the step where a deviation is detected. We call this the *minimum interpretation of the delay* and we use similar minimum interpretations of delay

when insertion and substitution mutations involving shuffled steps are performed.

In each of the experiments with the blood transfusion and chemotherapy processes, the average deviation detection delay was small—the largest average was 2.31 steps—and in most cases it was close to 1. In critical processes, such as medical procedures, however, even a delay of 1 could be harmful, if some potentially dangerous step, such as *administer chemotherapy medications*, is performed before detecting the deviation.

To address the question of whether/how often harm might occur due to delayed deviation detection, we identified a set of potentially harmful steps for both processes. These are steps, such that if an error has occurred prior to their performance, performing them could potentially result in immediate harm. Two such steps from the blood transfusion and chemotherapy processes are *begin infusion of blood product* and *administer chemotherapy drug*, respectively.

Having identified the set of potentially harmful steps, we then inspected the mutated sequences described above to determine whether a potentially harmful step occurs between the mutation index and the index of deviation detection. For sequences for which this was the case, we manually analyzed whether the error (the mutation) could affect the potentially harmful step. If harm could occur as a result of the error, we counted the mutated sequence as one for which deviation detection delay could be potentially harmful. There were no cases where the delay could result in harm for the two processes we examined.

Potential Harm When Deviations Are Detected without Delay. We found some mutated sequences for which the deviation is detected at the index of mutation, i.e., there is no deviation detection delay, but harm could potentially still be done (third row from the bottom of the table in Figure 2). In experiments 2, 3, 5, and 6, this was due to mutating a sequence by inserting or substituting in a harmful step. In general, if the error is a commission of a harmful step (e.g., *administer a drug*), a deviation cannot be detected before the harmful step is started because the sequence of performed steps up to the index where the error is made would be a legal sequence through the process model.

In experiments 1, 4, and 7, the cases where potential harm could occur, even when there is no deviation detection delay, were due to omitting a step or a subprocess that a) can immediately precede a harmful step, and b) can affect that harmful step. For example, in the blood transfusion process model, the subprocess of verifying the blood product immediately precedes the step *begin infusion of blood product*. Thus, if steps from this subprocess (such as *ensure that blood product has not expired*) are omitted, or the subprocess is omitted altogether, the deviation cannot be detected until the step *begin infusion of blood product* is started. The 50 cases in experiment 7 of mutants in which harm could occur even when there is no detection delay are due to omitting the subprocess *verify blood product information*.

Such structures represent process vulnerabilities with respect to the proposed deviation detection approach. They also represent vulnerabilities in general, as there is little opportunity for process performers to realize that an error is made before they start a potentially harmful step. A possible strategy to deal with such process vulnerabilities is to introduce a non-harmful step before the potentially harmful one. In fact, such steps are already in place in some medical procedures, such as surgeries where the clinicians performing the surgery are required to stop at certain points of the procedure and confirm that everyone has performed the necessary steps and is aware of the relevant information before proceeding further. The presence of such verification steps would allow the proposed deviation detection approach to detect deviations when such verification steps are performed and before potentially harmful steps are started.

Running time of the deviation detector. The running time results for the blood transfusion process are shown in the last two rows of the table in Figure 2. It took less than 6 seconds to determine whether a sequence of about 21.5 steps, on average, is a deviant; for the mutated sequences where exceptions were disallowed, it took around 13 seconds to determine whether a sequence of about 70.5 steps, on average, is a deviant. This results in less than a third of a second per step in a sequence. The running time of the deviation detector was similarly low for the chemotherapy process. Given that humans usually take more than a third of a second to perform an activity in a medical process, the running time results indicate that the deviation detector could detect deviations in real time before harm is done as a result of a deviation.

Threats to validity. The experimental evaluation was synthetic—we did not monitor a real executing process and did not apply the deviation detection approach to real process executions. The experimental evaluation was based on models of two medical processes. Even though the models were relatively large and complex in terms of covering a large set of process executions (including exceptional executions and concurrency within a single process execution), the results might change if the size or the complexity of the models increases or models of different processes are used.

We mutated the generated sequences by performing single-step deletions, insertions, and substitutions and also deletion of subprocesses. The results might change if mutations that represent different kinds of errors are performed or if multiple errors are considered.

Limitations of proposed deviation detection approach. Even though the preliminary investigation of the proposed deviation detection approach is promising, there are several research challenges that need to be tackled before

the approach can be applied in clinical settings. As discussed in section 2.2, the deviation detection approach relies on receiving an accurate sequence of performed steps of interest from the Process Execution Monitor. Capturing what human process performers do in an accurate and timely manner, however, may be difficult. We expect the use of electronic devices in processes will facilitate process execution monitoring. For example, starting to receive infusion data from an infusion pump could be automatically interpreted as having started the step *begin infusion of blood product*; similarly, when patient height and weight data are entered in an electronic medical record, this could be an indication that the step *measure height and weight* was performed.

While the use of electronic devices in processes increases the opportunities for monitoring process executions, events from electronic devices could be misinterpreted. Furthermore, electronic devices cannot capture certain steps in processes, such as cognitive steps (e.g., a doctor making sure the patient information on two artifacts matches). Human scribes, whose participation in medical processes seems to be increasing[4], can capture some steps that electronic devices cannot.

The success of the proposed deviation detection approach depends on the accuracy and the appropriateness of the process model as well. Creating a high-quality process model, however, can be challenging, given the complexity of some medical processes. We have been investigating techniques for eliciting and validating process models and have applied them successfully to several real-world processes[9,13,19]. We believe the criticality of certain processes warrants the time and effort needed to create high-quality process models that can in turn be leveraged to support continuous process improvement via various static analyses (e.g., model checking[20], fault-tree analysis[21], and failure-mode and effets analysis[22]) and to support deviation detection and other aspects of online process guidance (e.g., smart checklist[23]).

6 Conclusion and Future Work

This paper proposes an approach for online deviation detection to catch human errors in complex medical processes before harm is done. The approach relies on a mechanism for monitoring an executing process and on a detailed model that specifies how the process should be performed. We identify important issues related to the feasibility of this approach and evaluate that approach by applying it to detailed realistic models of two medical processes.

The initial evaluation of the deviation detection approach is promising. Delayed deviation detection rarely arose in the studied medical processes and when it did arise, no harm to the patient could occur as a result of the delay. The running time of the deviation detector is low relative to the human speed of performing process activities, suggesting that it could be used for online deviation detection. We also identify some vulnerabilities in the studied process models with respect to online deviation detection and suggest approaches for reducing such vulnerabilities.

The initial investigation of the deviation detection approach has suggested some interesting future research directions. When a deviation is detected, it might be useful to not only inform process performers about it, but to also provide some additional information that could help them identify potential error(s) and plan recovery actions. Examples of such information are possible indexes in the sequence of performed steps where an error might have occurred, as well as a ranked list of potential errors. We are exploring approaches for providing such information.

In this work, we studied the delayed deviation detection issue empirically. It will be useful, however, to also develop analytical approaches for determining an upper bound on possible deviation detection delays given a process model and assumptions about the errors that might occur. We are currently exploring such approaches. We are starting by assuming that only simple errors can occur (e.g., a single omission of a single step) before considering more complex errors and combinations of different errors.

Given the initial evaluation of the deviation detection approach and the recent developments in healthcare that could enable monitoring of executing processes, we believe the proposed approach can augment current approaches for online guidance (such as checklists) in medical processes and help catch errors before harm is done.

Adapting a Clinical Data Repository to ICD-10-CM through the use of a Terminology Repository

James J. Cimino, MD; Lyubov Remennick, MD
Laboratory for Informatics Development, NIH Clinical Center, Bethesda, MD

Clinical data repositories frequently contain patient diagnoses coded with the International Classification of Diseases, Ninth Revision (ICD-9-CM). These repositories now need to accommodate data coded with the Tenth Revision (ICD-10-CM). Database users wish to retrieve relevant data regardless of the system by which they are coded. We demonstrate how a terminology repository (the Research Entities Dictionary or RED) serves as an ontology relating terms of both ICD versions to each other to support seamless version-independent retrieval from the Biomedical Translational Research Information System (BTRIS) at the National Institutes of Health. We make use of the Center for Medicare and Medicaid Services' General Equivalence Mappings (GEMs) to reduce the modeling effort required to determine whether ICD-10-CM terms should be added to the RED as new concepts or as synonyms of existing concepts. A divide-and-conquer approach is used to develop integration heuristics that offer a satisfactory interim solution and facilitate additional refinement of the integration as time and resources allow.

Introduction

Many patient diagnoses are recorded in electronic databases using codes from the International Classification of Diseases, Ninth Revision (ICD-9-CM, or I9 for short).[1] When these data are included in longitudinal databases, such as clinical data repositories, challenges arise with each annual I9 update. For example, when searching for patients with septic shock, a researcher looking for data prior to 2008 would need to use the I9 codes *785.59*[*] and *998.02* (*Shock without mention of trauma, not elsewhere classified* and *Postoperative shock, septic*, respectively). However, a longitudinal study of patient records coded with the I9 code *785.59* would show a sharp decrease in incidence in 2008. Unfortunately, this is not due to development of effective measures for the prevention of septic shock but rather due to the addition of the I9 code *785.52* (*Septic shock*), with a concomitant change in the implicit meaning of *785.59* and a corresponding decrease in its use to code data. Researchers are often unaware of how such changes impact their work.[2] Mitigating impact of updates on the use of data repositories requires special measures.[3]

Such challenges are likely to be even greater for US researchers when, in 2014, I9 is replaced by the International Classification of Diseases, Tenth Revision (ICD-10-CM, or I10 for short).[4] I10 is much larger than I9; some of this increase is due to more finely grained terms (for example, *Postoperative Shock, Septic* is being replaced by the three terms *Postprocedural septic shock, initial encounter*, *Postprocedural septic shock, subsequent encounter*, and *Postprocedural septic shock, sequela*). I10 also contains terms that are similar, but not synonymous, with I9 terms (for example, *Septic shock* is being replaced by *Severe sepsis with septic shock*). Past I9 updates, involving dozens or hundreds of changes pale in comparison to the change that I10 brings, with tens of thousands of new codes.

We have previously described a method for coping with annual I9 updates through the use of a controlled terminology resource that maps multiple external terminologies to a single, coherent terminology for use within a single institutional clinical data repository.[3] This paper describes the application of that methodology to adapt to the inclusion of I10 data into a repository that contains patient diagnostic data coded in part with I9.

Background

The Biomedical Translational Research Information System (BTRIS)

BTRIS is a repository of clinical research data collected at the Clinical Center, a 240-bed hospital on the National Institutes of Health campus in Bethesda, Maryland. It includes data from electronic health records and clinical trials management systems dating back to 1953. Along with clinical notes, laboratory test results, procedure reports, vital sign measurements, medication administration records, electrocardiograms, radiologic images, mass spectrograms, and exome data, BTRIS includes 1.9 million discharge diagnoses assigned to hospital admissions, coded in I9.[5]

[*] In this paper, codes and terms from the various versions of the International Classification of Diseases will be distinguished by the use of a different typeface.

The Research Entities Dictionary (RED)

The RED is a terminology repository modeled after Columbia University Medical Center's Medical Entities Dictionary (MED).[6] The RED contains all the terms from the various controlled terminologies that are used by each of the BTRIS data sources to code their data. Each term is mapped to a corresponding concept in the RED, usually in a one-to-one manner, although where terms from multiple sources are clearly synonymous, they may be mapped to single concepts. Each concept is assigned a unique identifier (the "RED Code"), which is stored with the source data in BTRIS.

RED concepts are organized in a directed acyclic graph of hierarchical is-a relationships that can be used to query BTRIS in a class-based manner. Using a single RED code, one can find all patients with a diagnosis of any infectious disease, any foodborne infectious disease, any disease caused by the infectious organism Salmonella, or a particular disease (e.g., typhoid fever). Terms from disparate data sources are organized into the same classification structure so that, for example, a query for a disease term will retrieve data coded with I9 codes from the current EHR and previous Clinical Center EHRs, rare disease terms coded by the Medical Records Department, and problem list terms from one of the clinical trials management systems. Figure 1 shows an example of the RED hierarchy.

RED maintenance is an ongoing task, involving two full-time ontologists. Changes to source terminologies must be characterized as changes in syntax and/or semantics. For example, if a data source changes the name of a term (syntax), a determination must be made as to whether the change reflects a minor name change (no change in meaning, requiring a simple update to the term information assigned to the corresponding RED concept) or a major name change (a change in meaning, requiring retirement of the existing RED concept the creation of a new one).[3]

The addition of a new data source to BTRIS usually requires addition of one or more new terminologies in the RED. Here the task is somewhat different. The first priority is to make sure there is a RED concept that corresponds to each source term; this allows data to be stored in the BTRIS database and supports simple queries (e.g., "get all the patient diagnoses"). The second priority is to place the new concepts into the existing RED hierarchy, or add new hierarchical concepts, as appropriate to the meaning of the terms; this supports the more sophisticated class-based queries (as described in Figure 1). Ideally, if the new term is synonymous with an existing source term, it will be added as a synonym to an existing RED concept. However, this usually requires time-consuming manual review and is actually the lowest priority. Redundant concepts clutter the RED and might confuse a user looking for terms with which to search BTRIS, but they do not adversely affect retrieval of data and can be corrected retroactively by merging concepts in the RED and replacing RED Codes in BTRIS.

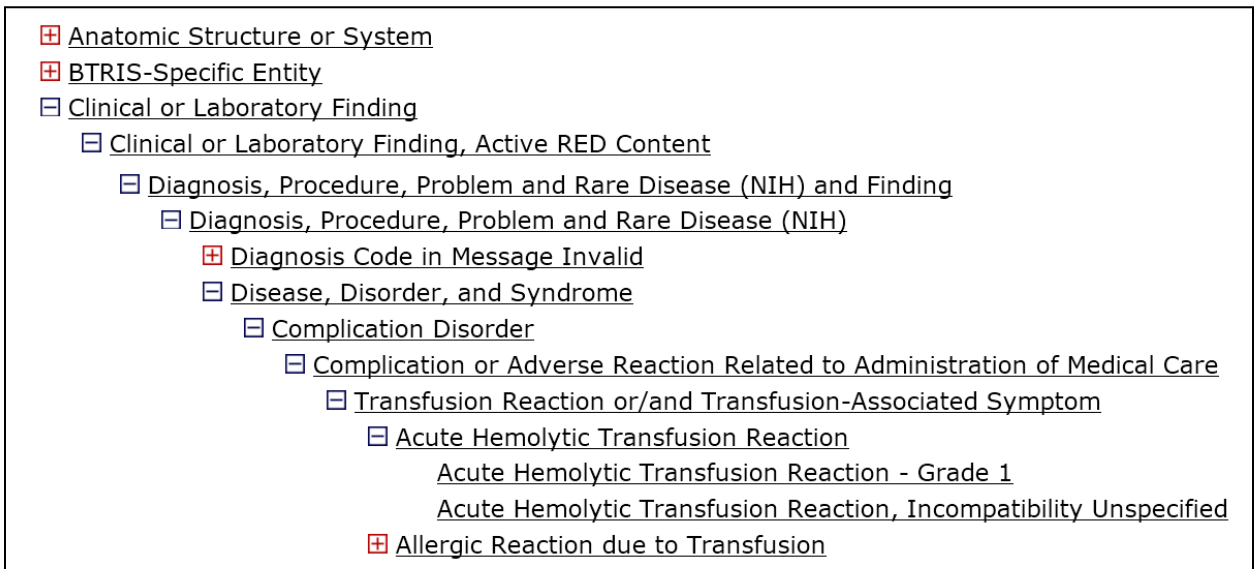

Figure 1: A sample of concepts in the RED hierarchy. The concept "Acute Hemolytic Reaction – Grade 1" corresponds to a term from the system in the Clinical Center's Department of Transfusion Medicine, while "Acute Hemolytic Transfusion Reaction, Incompatibility Unspecified" corresponds to the I9 term with the code *999.84*. Note that a BTRIS user wishing to retrieve data about acute hemolytic reactions can simply request the parent concept, "Acute Hemolytic Transfusion Reaction" and data coded by all three concepts will be retrieved.

General Equivalence Mappings (GEMs)

The National Center for Health Statistics (NCHS) has developed a bidirectional general equivalence mapping (GEM) system to assist users of I9 and I10 in deciding how to change their coding practices and understand how data coded in I9 and I10 relate to each other. NCHS, together with the Centers for Medicare and Medicaid Services (CMS) has published files that can be used as the basis for translating between I9 and I10 terms.[7]

The GEM mappings consist of two files, one in which each I9 code is listed at least once, with a set of flags associating it with one or more I10 codes, and one in which each I10 codes is listed at least once, with a set of flags associating it with one or more I9 codes.[8] The flags consist of five digits, with meanings as shown in Figure 2.

I10 Code	I10 Name	I9 Code	I9 Name	GEM	Meaning
A00.9	*Cholera, unspecified*	*001.9*	*Cholera, unspecified*	*00000*	Synonymous
A01.00	*Typhoid fever, unspecified*	*002.0*	*Typhoid fever*	*10000*	I10 term similar to I9 term
A01.01	*Typhoid meningitis*	*002.0*	*Typhoid fever*	*10000*	Another I10 term similar to the same I9 term
A02.1	*Salmonella sepsis*	*003.1*	*Salmonella septicemia*	*10111*	I10 term best expressed with two
A02.1	*Salmonella sepsis*	*995.91*	*Sepsis*	*10112*	I9 terms (one scenario)
R40.2131	*Coma scale, eyes open, to sound, in the field*			*01000*	No mapping in I9

Flag Position		Interpretation
1	"Approximate"	0=exact match (synonymous), 1=approximate match (similar meaning)
2	"No Map"	0=some plausible mapping; 1=no plausible mapping
3	"Combination"	0=mapping to single term, 1=mapping to multiple options ("scenarios"), multiple terms, or both
4	"Scenarios"	With the Combination flag=1, a coding option; may be one scenario (numbered "1") with multiple options or multiple scenarios (numbered "1", "2", etc.) each with one or more choices
5	"Choice"	With the Combination and Scenario flags, one or more options for a Particular scenario (numbered "1","2", etc.)

Figure 2: Understanding the General Equivalence Mapping Codes. Examples of the I10 to I9 GEM mappings are shown, with interpretation of each of the five flag positions. Note that GEM mapping files do not include term names; these were added here for clarity.

Methods

Our general approach to adding I10 terms to the RED is to examine the pairings with I9 codes provided in the GEMs and use the flags to suggest synonymy with or relationships to existing RED concepts. Relationships can include "child" (added to the hierarchy under the existing concept), "parent" (inserted into the hierarchy above the existing concept), or "sibling" (added to the hierarchy under the parent(s) of the existing concept). Using a "divide and conquer" approach,[9] we partitioned GEM mappings according to the following steps:

1. GEM flags were used to create four partitions: 00000 – *potential synonyms*; 10000 ("similar" flag set) – *potential children, parents or siblings*; 101xx ("combination" flag set) - *potential children, parents or siblings*; and 01000 ("no mapping" flag set) – *new concept*

2. We divided the 10000 ("similar") partition into four partitions based on the cardinality of terms involved the I10-to-I9 mappings: *one-to-one mappings*, *one-to-many mappings*, *many-to-one mappings* and *many-to-many mappings* (note that the "potential synonyms" partition is by definition one-to-one and the "combination" partition is by definition one-to-many or many-to-many but was not further subdivided; thus, the fourth and fifth flags were not considered further, as their complexity requires case-by-case review)

3. Each of the above partitions (except the *new concept* partition, in which there are no corresponding I9 terms) were further divided into based on the whether any of the I10 or I9 terms contained the word "other" or the phrase "not elsewhere classified"; this was done because the semantics of these terms can never be precisely determined (even the GEM mappings state that identical term names are not synonymous if they are "other" terms[10]); the phrases "not otherwise specified" and "other and unspecified" were excluded from this

consideration since they actually equivalent to the generic class terms; regardless of their original partition, "other" mappings were evaluated as *potential children, parents or siblings*

4. Within each of the resulting partitions (except the *new concept* partition, in which there are no corresponding I9 terms), we performed automated comparisons of the I10 and I9 terms names for similarity:
   - Name match: exact match between terms; treated as *potential synonyms*
   - Normalized name match: terms were normalized as follows prior to comparison: all letters capitalized, punctuation removed, words replaced with preferred forms using a set of previously described word synonyms,[11] stop words ("A", "AN", "AND", "OR", "THE", "UNSPECIFIED", and "WITH") removed, and remaining words sorted alphabetically; for example, "Typhoid meningitis" becomes "MENINGITIDES TYPHOID"; treated as *potential synonyms*
   - Non-name match: no exact match between original names or normalized names; treated as *potential children, parents or siblings*

We manually examined each partition to identify patterns of semantic relationships between the I10 and I9 terms. For example, we did not automatically assume that I10 and I9 terms were synonymous just because their GEM mapping was "00000" if the names (or normalized names) did not match. Similarly, we did not assume that terms were *not* synonymous just because their GEM mapping was "10000" if their names (or normalized names) matched and they were not "other" terms.

These manual examinations of each partition led to development of general decision rules, or heuristics, to apply to each I10-I9 pair. Based on the decions, the following actions were taken:

synonym - I10 term code and name added to existing I9 RED concept

child - new term added as child of existing I9 RED concept (new leaf node in hierarchy)

sibling - new term added as new leaf node child of the parent(s) of the existing I9 RED concept

parent - new term added as parent of existing RED concept (inserted into hierarchy above I9 concept).

Once the general rule was established, we began to manually review these decisions to find exceptions. This process allowed us to add I10 terms to the RED in bulk fashion with subsequent review and, where appropriate, correction (split synonyms into new and old concepts, merge synonymous concepts, and reclassify new concepts).

Results

General RED Inclusion Rules for Partitions of GEM Mappings

Table 1 shows the size of each of the partitions of GEM mappings. Also shown are the initial mapping decisions for each partition, plus any decisions made based on manual review to date. Table 2 shows examples of each of these mappings.

For example, all "non-other" I10-I9 pairs for which the GEM "synonymous" (00000) mapping were initially considered to be synonyms. After manual review, we agreed with these mappings for all pairs in which the names (or normalized names) matched. Figure 3 shows an example of a synonym mapping in the RED. However, our manual review of the "non-name match" partition discovered 95 pairs that we considered to be non-synonymous, such as the I10 term Newborn (suspected to be) affected by maternal hypertensive disorders (*P00.0*) and the I9 term *Maternal hypertensive disorders affecting fetus or newborn* (*760.0*); we understand the I9 term as a diagnosis that is applied to the parent of the newborn and the I10 term as a diagnosis that is applied to the newborn itself.

An example of combination mappings can be found with the I10 term *Salmonella sepsis* (*A02.1*), which has a GEM map of 10111 to the I9 term *Salmonella septicemia* (*003.1*) and a GEM map of 10112 to the I9 term *Salmonella sepsis* (*995.91*). In this example, there is only one scenario (fourth flag) with two choices (fifth flag). In this case, we determined that the I10 term should be added as a new concept in the RED and placed in the hierarchy under the existing concepts for both of the I9 terms.

Table 1: Partitions of GEM Mappings Based on Flag Pattern, Combinatorial Patterns, “Non-Other” versus “Other” Terms, and Type of Name Matching. RED addition decisions are shown as counts of synonyms, siblings and children; letters next to decision counts refer to examples shown in Table 2.

GEM Flags	I10 to I9 Mapping	"Non-Other" vs. "Other" Terms	Name Matching	Mapping Decision

Repeating Patterns of Many-to-One Mappings

By far, the largest partition is the many-to-one approximate (10000) mappings, with 57,236 I10 codes mapping to 4192 I9 codes. Our initial assessment was that most of these mappings represent a refinement of an I9 term into many I10 terms. However, when we reviewed specific sets of mappings, we noticed recurring patterns. For example, 996 of the I9 codes map to exactly two I10 terms. In 261 cases, one of these is an "other" term and the other is not. More broadly, the mappings to 768 I9 terms (18.3%) include exactly one "non-other" I10 term. Examination of these sets shows that, in general, if the I9 term is represented as "X", one I10 term can be represented as "Other specified X" and the remaining I10 terms are more specific forms of X. If this is true for all such "one 'other' and many 'non-other'" patterns, we can with confidence add all of these I10 terms as children of their

Figure 3: Example of a RED concept that maps to an I9 term and an I10 – that is, the terms are considered synonymous. This is also a term used by an NIH clinical trials data management system (CRIMSON).

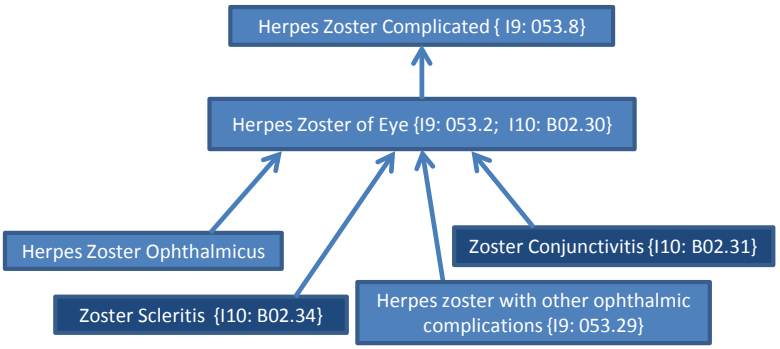

Figure 4: Example of RED hierarchy after inclusion of I10 terms. Light boxes represent concepts that were in the RED prior to inclusion of I10 terms; dark boxes represent newly added concepts. I9 and I10 codes are shown in {curly braces}.

corresponding I9 term. A similar rule may apply for the 2498 (59.6%) I9 terms that have no "other" I10 terms in their set of maps.

Class-Based Retrieval of BTRIS Data across ICD Versions

The ultimate purpose of all this work is to support the storage and retrieval of BTRIS data in as accurate and seamless a manner as possible. A perfect ontology is probably impossible, given all the subtle nuances of the differences among and between I9 and I10 codes. Recoding all the I9 data with I10 codes is not practical and would likely lead to inaccuracies. Requiring users seeking to retrieve data to select a code from each terminology version might be accurate but would be confusing and awkward. The I10 update we are applying to the RED provides a practical solution. Figure 4 shows an example of the new hierarchy of RED concepts that include mappings to I9 and I10 terms. BTRIS supports class-based queries so that a user could, for example, query for the RED concept Herpes Zoster Complicated and retrieve all data coded with the I9 codes 053.8, 053.2 and 053.29 and with the I10 codes B02.30, B02.31 and B02.34.

Discussion

A clinical data repository that combines I9 and I10 data without a coordinated terminology solution has two options: either re-code all the old I9 data with I10 or force users to query using both I9 and I10 terms. Our use of a single repository terminology, the RED, provides significant benefits to our users: they use a single terminology to perform queries that includes not only I9 and I10 terms but several other local diagnosis terminologies. The RED also provides the benefit of multiple hierarchies, so that users are not restricted to either of the single hierarchies of in I9 or I10, and they can still query for specific I9 or I10 terms if desired. The ontology approach – regardless of how the maintenance is accomplished - reduces the need to include multiple terms in queries. While this probably improves query execution somewhat, the real saving is a reduction in the BTRIS user's effort to construct a comprehensive query.

RED maintenance requires significant human effort. The manual integration of a new terminology of I10's magnitude would require many months of work, much of it mind-numbing and prone to error. The GEM mappings have been of tremendous benefit for providing a first approximation of synonymy and classification of I10 terms. The result is that I10 terms can be added quickly and be made useful immediately for both storing and retrieving patient data. Where revisions are required to merge redundant terms, split ambiguous ones, or reorganize the hierarchy, the amount of effort needed is no more that would be needed if we were to try to get everything "right" prior to loading I10 into the RED. Meanwhile, our use of GEM-based heuristics allows us to have a working, integrated repository while proceeding with "tuning" the RED. We now have the luxury of prioritizing our reviews based on the I10 terms as they actually start appearing in patient records.

In addition to continued work at reviewing and revising the I10 additions to the RED, we will continue to study the patterns of the many-to-one "similar" GEM mappings to determine if they can be used to improve the relationships between I9 and I10 terms. We will also need to make changes as updates to I10 occur; one of these has taken place already.

While the GEMs are obviously limited to use with I9 and I10, their existence raises the possibility of similar approaches to other mappings, such as between various drug terminologies or between I10 and the Systematized Nomenclature of Medicine (SNOMED-CT). The actual methods used and level of effort needed to develop the GEMs is not published, but it is interesting to consider whether similar tools could be developed for other term mappings.

When our ontology-based method for coping with I9 changes was originally published in 1996, Tuttle and Nelson praised it in an accompanying editorial but lamented the need for having to carry out "reverse engineering". They went on to say:

> Such methods should be viewed as necessary short-term expedients only, and all parties concerned should work toward an incremental plan by which the intent of changes to controlled health-care vocabularies can be made both explicit and machine processible. Only then can the comparability of patient descriptions be sustained.[12]

We, too, await such changes.[13] In the meantime, while the GEMs are not machine processable, they are at least machine readable and appear to be based on sound terminologic principles. Furthermore the ontologic approach of mapping terms to concepts and then coding data based on those concepts has proven to be a valuable precedent that continues to provide value in dealing with local and standard terminologies alike.

Conclusion

The practice of using an ontology that integrates disparate clinical terminologies has proven to be a powerful method for meeting the challenges of adapting a clinical data repository to include I10 data while maintaining the value of legacy I9 data. Our approach is able to take advantage of the GEM mappings from CMS to provide a rapid solution that can evolve gracefully.

Abstract

Patient- and Family-Centered Care (PFCC) is essential for high quality care in the critical and acute-specialty care hospital setting. Effective PFCC requires clinicians to form an integrated interprofessional team to collaboratively engage with the patient/family and contribute to a shared patient-centered plan of care. We conducted observations on a critical care and specialty unit to understand the plan of care activities and workflow documentation requirements for nurses and physicians to inform the development of a shared patient-centered plan of care to support patient engagement. We identified siloed plan of care documentation, with workflow opportunities to converge the nurses plan of care with the physician planned To-do lists and quality and safety checklists. Integration of nurses and physicians plan of care activities into a shared plan of care is a feasible and valuable step toward interprofessional teams that effectively engage patients in plan of care activities.

Introduction

Patient- and Family-Centered Care (PFCC) is associated with better clinical outcomes in the critical care setting, improved decision-making for patient-centered goals of care, increased family satisfaction, decreased length of stay, and increased care-giving ability by family members post-discharge.[1–5] Effective PFCC in the acute and critical care setting requires the coordinated assessment and active consideration of the psychosocial needs and preferences of patients and families by the interprofessional care team through continuous engagement and involvement in discussions and decision-making.[2,6] Critical care patients are often too ill to advocate for themselves, making engagement of patients' families in decision-making discussions especially important; yet, few specific strategies to operationalize and sustain family-centered care in adult patients have been published.[1] We believe that a valuable and novel strategy is to provide hospitalized patients and families with a means of viewing their plan and providing feedback about their plan to providers in real-time.

Unfortunately, within the high technology and high acuity critical and specialty care environment, patient and family needs related to care planning and transitions of care, such as increased family care-giving or end-of-life decisions, are often overlooked.[2] Without appropriate support and information, family members experience undue burden associated with the increased anxiety, ineffective coping, spiritual distress, and impaired decision-making ability related to their family member's critical illness and end of life care. Likewise, patients in acute and critical care, when well enough to engage, seek information about their care and care team.[7,8] Engagement of patients and families occurs through the process of shared decision-making, which is a method to support patients and families with healthcare provider expertise while incorporating patient's preferences to reach patient-centered decisions for goals of care.[9] A multidisciplinary effort in 2007, spearheaded by the American College of Critical Care Medicine (ACCM), developed the clinical practice guidelines for support of the family in the patient-centered intensive care unit.[2] This guideline, consistent with other literature, specifically recommends: shared decision-making, early and repeated discussions with the patient and family at the first sign of ineffective coping, improved consistency in communication from the interprofessional care team, and staff education for PFCC.[2,10–12] Nurses and physicians, as the clinicians that interact most frequently and consistently with critical care patients and their families, are in an ideal position to engage patient/family members in shared plan of care discussions. However, first, nurses and physicians must share their plans of care with each other to establish a common plan for effective exchange and engagement with patients and their families. Critical and specialty care (e.g., oncology) are a highly collaborative

environments where clinicians seek out knowledge from other clinical professions and specialties, but there is a lack of tools for interprofessional exchange of plans of care. Failure for the care team to effectively communicate is associated with patient/family stress, nurse stress, patient safety errors, inefficiencies, and excessive lengths of stay.[1-5]

Ensuring that family members receive consistent and timely information from clinicians on the interprofessional care team is one of the greatest evidence-based practice (EBP) gaps within the model of family-centered care.[13] Poor team communication is associated with mismatched patient care goals.[14–16] For effective shared decision making conversations to occur between the patient/family dyad and the interprofessional care team, nurses and physicians must first establish common ground.[2] In prior work, we found that clinicians, including nurses and physicians, sought to understand care interventions delivered by other professions.[17] Active alignment of profession-specific care priorities with patient-centered priorities is a critical part of integrated care and the degree of knowledge sharing between professions increases as care becomes more patient-centered.[18,19] Currently, as a healthcare system we do a poor job at asking patients to provide their feedback with regard to their plan of care, particularly their problems, preferences, goals, schedule, and evaluation of their status. There are few use cases and even fewer evaluation studies in the literature of patient-centered knowledge sharing tools among patients, nurses, and physicians.[20,21] Sustainable and feasible patient-centered team behavioral interventions remain a challenge, but recent work points to active knowledge sharing as a critical component in effective models of patient-centered care.[19,22] This study is part of a large multi-year and multi-aim project that will provide hospitalized patients and their families with an iPad-based patient-centered toolkit (PCTK) to engage with their health data and plan of care as well as access information resources and communicate with their care team. The development of an electronic patient-centered toolkit (PCTK) for sharing the plan of care presents a ripe opportunity to: 1) understand the processes and plan of care activities that exist for patients, nurses, and physicians in critical and specialty care, 2) define opportunities for patient-centered engagement and alignment of plan of care activities, 3) define requirements for patient-centered plans that seize opportunities for clinician and patient engagement and avoids increasing clinician documentation requirements by considering existing processes and activities, and 4) provide patients with a novel mechanism to communicate real-time feedback and participate in the development of their plan of care.

The aims of this study are to: 1) Describe current clinical plan of care activities and workflow, 2) Identify opportunities to integrate the care teams' plan of care activities and workflow for care team engagement with patients and families, and 3) define workflow requirements for a plan of care that is integrated across the care team and shared with patients. This shared patient centered plan of care was deployed on the study units in May 2014.

Methods

This study took place at a large academic medical center in the Northeastern United States. We conducted observations on a Medical Intensive Care Unit (MICU) and Oncology Acute Care Unit (Oncology Unit) to understand the distinct and shared workflows of nurses and physicians and opportunities to engage with patients in development of the shared patient centered plan of care. The focus of this study was on nurses' and physicians' engagement with plan of care activities for the purpose of sharing an integrated team-based plan of care with the patient and family, to form a patient-centered plan of care. The study was reviewed and approved by the Partners HealthCare Human Research Committee.

Seven observations were conducted, 4 observations on the MICU and 3 observations on the Oncology Unit. Observations lasted between 2 and 4 hours. Each observation was conducted by 2-5 study investigators consisting of 2 nurse researchers, 1 physician, and 3 research assistants. The participants observed included nurses, residents and physicians assistants (PAs), attending physicians, fellows, charge nurses, staff nurses, pharmacists, patients and families. PAs managed patients in the Oncology Unit, but not in the MICU.

Study investigators took field notes during the observations; field notes were specifically targeted at activities and communication related to plan of care. Observational findings were validated using member checks during individual and group semi-structured interviews with clinicians. These interviews were conducted with 1-7 clinicians. During the interviews, clinicians were presented with 1) observational findings describing the current clinical plan of care activities and workflow, 2) Visio diagrams to confirm opportunities to integrate PCTK into plan of care workflow for patient and clinician engagement, and 3) user interface prototypes (paper-based screen shot mock-ups) to confirm workflow and documentation requirements for a shared patient centered plan of care. After each observation and interview session, the investigators met for peer debriefings to review field notes, reflect on

past observations, iteratively identify emergent themes, and collectively add to, form consensus on, and refine requirements.

RE-AIM Conceptual Framework

The RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) framework was used to understand existing processes and workflow related to plan of care activities, identify opportunities for patient-centered engagement, and avoid potential unintended consequences and poor adoption.[23] RE-AIM was developed specifically to direct the design and conduct of rigorous studies of real world implementations of efficacious interventions to facilitate their translation of research into practice and has been specifically applied to informatics implementations.[23] We used the RE-AIM framework to formulate the following targeted questions to consider during our observations and interview data collection:

- Reach: What are the documentation and workflow opportunities for nurses and physicians on the MICU and Oncology Units to engage with patients in a shared patient-centered plan of care?
- Effectiveness: What are the required plan of care activities and documentation for nurses and physicians?
- Adoption: What are the current clinical workflow processes related to plan of care that nurses and physicians engage in and must be considered for user acceptance and workflow fit?
- Implementation: What are the technical requirements for integrating nurses and physicians plan of care activities?
- Maintenance: Is the intervention sustainable overtime? [*Will be evaluated after 'go-live' implementation*].

Results

Care Unit Process Categories for Plan of Care Activity Workflow and Opportunities for Engagement

We found that plan of care activities were distributed among a number of clinical care unit process categories. To facilitate identification of opportunities to engage nurses and physicians with patients in plan of care activities, we used the clinical care unit process categories that emerged from the data to categorize the observational data. We identified six high-level clinical care unit process categories: Intake/Admission, 24 hours post-admission, Daily Rounds, Family Meetings, Discharge, Handoff/End-of-Shift Documentation.

Patient admission to a critical or specialty care unit is a busy time during which a patient is stabilized (if needed), assessed, and evaluated to determine their immediate needs/goal of care and a plan that meets those needs. Interview data confirmed that the plan of care may not be established immediately when a patient is admitted to the unit, but is established within the first 24 hours of admission. The first 24 hours after a patient is admitted was a critical opportunity for holding an initial plan of care discussion with patients and family so that the patient's goals of care could be established. The nurses interviewed conveyed that during an initial family meeting the patient and family are typically focused on critical medical issues, patient acuity, and seek information regarding the patient's treatments and logistics of the hospital stay.

After the initial 24 hours, Daily Rounds was the critical process used to evaluate plan of care progression over the past 24 hours and to revise the plan for the next 24 hours. Rounds were typically held outside patients' rooms and patients and families were not actively engaged in the rounds discussion on the two study units. Rather this time was afforded to the interprofessional care team to facilitate common ground and a shared understanding of the plan of care amongst the team members. Some clinicians noted that this workflow excludes the patient and family in a manner that was inconsistent with patient-centered care. Benefits cited by the clinicians of reserving a time for only clinicians to discuss the patient included the ability for the care team to efficiently and openly confirm, dispute, and ask questions about the patient's condition, diagnoses, therapeutic options, and share individual insights and communications that each clinician may have had with the patient and family or other clinicians.

Daily rounds on the MICU and the Oncology Unit have overlapping and distinct characteristics. Rounds on both units follow a consistent structure, which validated our prior work.[15,16,24] We observed and confirmed in interviews that the objective of rounds was to establish and discuss medically focused problems and goals for the next 24 hours. The documentation output from rounds included progress notes and to-do lists which were distributed and documented individually among care team members. In the MICU, the nurse was responsible for summarizing the team goals that were established during rounds and documenting those daily goals on a sheet that was posted outside the patient's door. Overall, the discussion was well-structured, but allowed for dynamic engagement of outstanding

issues highlighted by any team member. During rounds, the team referred to checklists to ensure certain items were discussed, including the patient's code status. However, discussions of other patient preferences beyond code status was rarely observed, but was validated as important when brought up by team members. When patient preferences *were* discussed, the attending physician and nurse were most frequently observed to initiate those discussions. In the MICU, there was a focus on daily checklists, sometimes referred to as "bundles," to ensure the patient's plan was aligned with known safety goals, evidence-based care, and quality metrics. Examples of the checklists ("bundles") include: the Ventilator Management Bundle, Catheter-associated Urinary Tract Infection (CAUTI) bundle, and the Central Line Bundle. The Quality and Safety Checklists used at MICU rounds also related to: restraints, nutrition, blood glucose checking, implementation of early physical therapy, deep vein thrombosis prevention, gastrointestinal ulcer prevention, communication with family, and code status.

The MICU nurses' summarization of the team goals was viewed as valuable for coordinated team-based care, yet the daily goals sheet that reflected this summarization was not part of the patient's formal medical chart and was discarded every 24 hours. For this reason, we conclude that there was no formal and permanent documentation that served as a central source of decisions or plan for reference and evaluation over time. When interviewed about the possibility of making the daily goals sheet computer-based for sharing among the interprofessional team and patient during and after rounds the nurses disagreed with the proposed workflow. The nurses stated that they use this daily goals sheet to quickly document the high level outcomes of rounds and quickly note tasks and To-Do's to complete that day. The nurses were not opposed to sharing the daily goals sheet with the team, as it was already available for others to view (posted outside the patient's room). Rather, the nurses were hesitant to make it computer-based; they referred to it as their "scut" sheet and felt that they needed a piece of paper to quickly take notes about the team's goals for the patient, tasks and To-Do's to refer to throughout the day. The nurses stated that all of the information on this daily goals sheet is formally documented after rounds, typically by the night shift nurse, in the nurses' plan of care. While the daily goals sheet is not recognized as a formal part of the patient's chart, the nurses' plan of care is a formal part of the patient's chart and may be a useful mechanism of communicating information that is meaningful to other members of the care team and patient.

Rounds on the oncology unit differed from the MICU in several ways. Only one team rounded in the MICU and the nurse cared for one to two patients per shift, facilitating the nurse's ability to participate as an integral part of the team during rounds. On the oncology units, several teams rounded simultaneously making it more difficult for the nurse to be present for each team's rounds. As a result, the PA or intern conducted a pre-rounding check with the nurse to identify important information to be shared on rounds. The oncology unit did not share a common checklist or "bundles," however, on the oncology unit many patients are admitted for specific treatment protocols that have a relatively well defined course, and our observations and interviews indicated that the team typically had a common understanding of the patient's anticipated progression. Informal handwritten notes were taken by PAs and interns during rounds, which were then entered into the online patient record and printed to be physically stored in the patient chart after rounds.

Family meetings are formal meetings scheduled with the family to discuss the patient's condition, reach common understanding about the goals of care, and agree on a plan. These meetings are held in the clinical unit's conference room and at a minimum include the attending physician or fellow, a nurse, the patient or health care agent, and family. The meetings are typically highly emotional, particularly meetings that are held "as needed" due to a patient's worsening condition. An attempt is made to hold a family meeting within the first 24 hours of admission and every couple of days after, although this is not always practical or achieved. Documentation of what was discussed is completed on a structured Patient/Family Communication Note that is part of the chart and may be completed by the social worker or attending physician. Our observations and interviews indicated that the Patient/Family Communication Note is often not completed and instead the attending physician may write a physician progress/daily note. A point of concern noted by a charge nurse is that these notes include variable and often insufficient levels of detail. For example, the charge nurse pointed out a family meeting note that stated: "DNR/DNI but will continue aggressive therapy" and explained that this plan is not clear because it does not specify which type of therapy, for what purpose, and the plan and schedule to reevaluate the patient. In addition to formal scheduled family meetings, informal meetings and updates are conducted with the family on a daily basis. These updates may be shorter, less formal discussions between the patient and/or family and the physician and/or nurse and they may occur over the phone, in the patient's room, or in the hallway of the clinical unit. The oncology unit has no specified plan for family meetings, using them only on an ad hoc basis. The PA teams return to the units in the afternoon to follow up with patients and families regarding changes or progress in the plan of care. Additionally,

as most acute care oncology patients are able to engage in their care, informal meetings with other providers (nurses, social workers, etc.) are regularly held at the bedside as needed.

Table 1. Care Unit Process Categories and Associated Opportunities for Engagement

Care Unit Process Categories	Ripe Opportunities for Clinician-Patient/Family Engagement with Shared Patient Centered Plan of Care
Admission	• *Introduction* of a shared patient-centered plan of care approach to patient/family

24hrs post admission	• *Teaching* by nurse with patient/family related to initial plan, medications, and procedures
	• *Identification* of
	  o Problems, preferences, and goals by patient/family
	  o Problems, goals, initial plan by care team

Daily Rounds	• *Data display* to care team during rounds captured from patient
	  o Patient identified problems, preferences, and goals
	  o Home/out-patient medications/therapy regimen
	• *Data capture* from care team during rounds to push to patient
	  o Leverage existing workflow to summarize goals and plan at end of rounds
	  ▪ Output to Nursing Shared Plan of Care
	  ▪ Output to Physician Shared "To-do" Lists and Safety and Quality Checklists
	• *Promote* discussion of
	  o Patient preferences among care team
	  o "Big picture" to consider if goals of care are aligned with patient condition and preferences
	  o Shared plan of care with patient/family in follow-up discussion after rounds

Family Meetings	• *Formalize* patient preferences and goals of care in context of treatment option • *Clarify* patient preferences and patient/family degree of certainty in decision-making • *Confirm* shared understanding of "big picture" of patient's condition • *Align* problems and specific plan with patient's goals of care and preferences • *Seek* patient/family decision logic and "if/then" plan (e.g., if patient does not respond to therapy after X time then re-examine goals of care) • *Provide* families with shared plan of care and sufficient time to consider plan • *Communicate* outcome of family meeting to care team that was not present
Discharge	• *Implement* patient progression framework prior to day of discharge
Handoff	• *Communicate* shared patient centered plan of care to next shift

During daily rounds, patients are deemed "cleared for discharge" if their condition permits. Patients on the MICU that are cleared for discharge typically wait about 6 to 24 hours for a bed to be available on step-down/acute care unit or a long term care facility. On the Oncology Unit a Patient Progression Model with Interprofessional Huddles was recently piloted due to delays in discharge and to facilitate team-based coordination and communication. The Patient Progression Model is a clinical process model that engages the team in actively and collaboratively identifying the expected date of discharge, location of discharge and any barriers to discharge, such as medications that need prior approval for oncology patients or physical therapy referrals. The hospital had determined that patient discharge was often delayed due to insufficient coordination of logistical reasons and dependencies, not medical reasons, and the Patient Progression Model is an organizational effort aimed at increasing the transparency of discharge dependencies through Interprofessional Huddles – frequent and short team-based discussions that may leverage a care coordinator and other members of the care team to coordinate and manage dependencies earlier during the patient's hospital stay. The Patient Progression Model with Interprofessional Huddles are promising workflows to engage the care team in a shared patient-centered plan of care. Yet, at this time, as a newly implemented pilot program, our ability to conclude how these workflows will be adopted and can be leveraged is limited.

In both the MICU and Oncology units, nurses document a plan of care on paper at the end of each shift. This is a continuous plan of care for the patient's stay on the unit as it is shared among each nurse caring for the patient and includes multiples shifts and days on the same paper. The nurses' plan of care includes a nursing problem list, relevant assessment data, goals, and interventions. The residents in the MICU update the "To-Do" list on a whiteboard every day after rounds in physician break-room. In addition to the To-Do list, physicians complete a

computer-based semi-structured medical problem list using an internally developed clinical information system. The medical problem list is refined during rounds and documented on each physician's daily note and used to inform the To-Do List. The "To-Do" list is shared by all members of the medical team, and primarily edited by the residents. The To-Do list is focused on items such as medications or procedures to order, laboratory results to review, consults to request, and family meetings to schedule. In our data collection, we observed that handoff at the end of a shift was used to convey the plan, any issues that arose during the past shift related to the plan, and outstanding issues that still needed to be addressed in the plan. These updates are incorporated into the nursing plan of care documentation and the physician "To-Do" list documentation.

Requirements for Nurse, Physician, and Patient Engagement with a Shared Patient Centered Plan of Care

Our observational and interview data indicated two existing documentation workflows that are feasible for data capture into a shared patient centered plan of care: 1) Nursing Shared Plan of Care documentation and 2) Physician Shared "To-Do" Lists and Safety and Quality Checklists (see Table 1). Both of these documentation workflows were paper- or whiteboard-based. The documentation was already shared among each profession, which eased some anticipated sociotechnical barriers to the development of a shared Patient-Centered Plan of Care. For example, we did not need to introduce the need for nurses to negotiate who is responsible for documenting the nursing plan of care and when the nursing plan of care documented should be completed. Likewise, the residents' and interns' responsibility for the Shared "To-Do" Lists and Safety and Quality Checklists had also already been negotiated. Therefore, the development of a shared patient centered plan of care that pulled from the nursing plan of care and physician checklists and "To-Do" Lists was seen as feasible and useful to the clinicians.

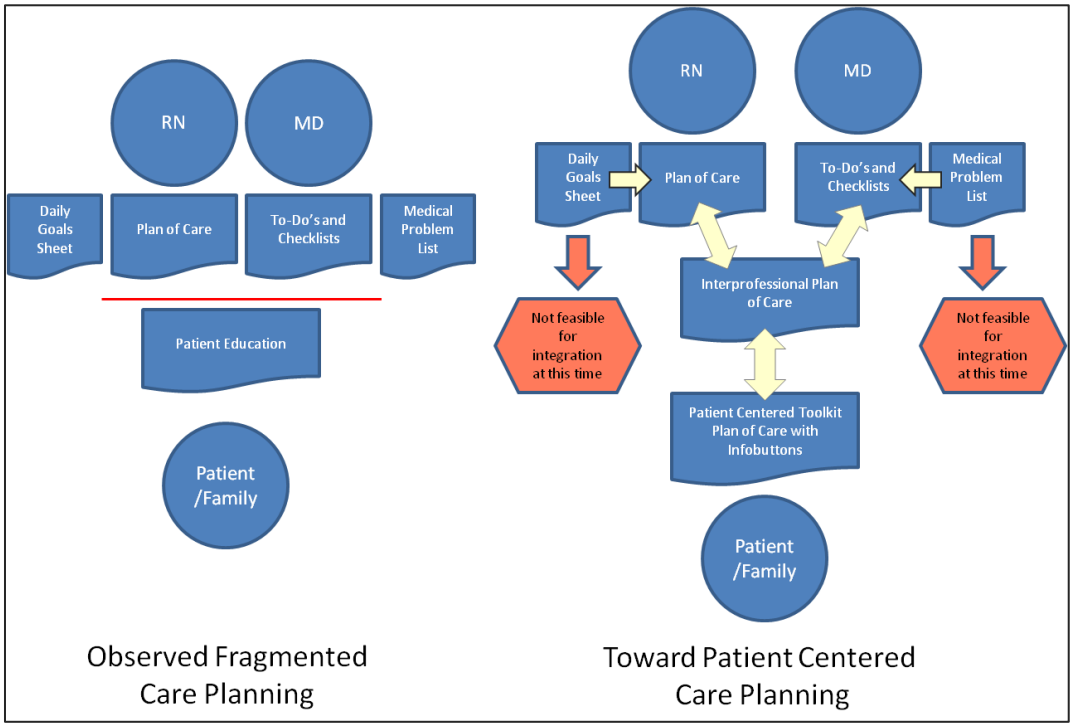

Figure 1. Toward Patient-Centered Care Planning Through Integration of Siloed Plan of Care Documenation

In the MICU, the residents and interns required the ability to document their "To-Do" List and Safety and Quality Checklists during rounds. The "To-Do" Lists include frequently documented tasks, such as the need to communicate with the surgical team or hold a family meeting. These frequently documented "To-Dos" could be structured and made available for selection, with the ability to add more detail or more "To-Dos" in free-text. The Safety and Quality Checklists required the ability to check off items daily during rounds and when appropriate provide a rationale for why an item was not completed. An analysis was required for checklist items that also existed on the nursing Plan of Care to determine the "source of truth" and level of sharing between each computer-based checklist. A core requirement for the To-Do list and Safety and Quality Checklists was the ability for the resident/interns to select "To-Do" and Checklist items to "push" to patient for viewing and that were Infobutton enabled.

During observations, Oncology clinicians identified rounds as a source of information exchange inefficiency, partially due to the informal process with which they recorded tasks. Thus, although a formal checklist and "To-Do" List was not part of the existing Oncology workflow; providers were willing to pilot a computer-based checklist during rounds that is being developed by the study team.

It is important to note that the physician/PA documentation related to the plan of care includes documentation of the medical problem list as well as the To-Do and Checklists. Based on clinical and technical stakeholder engagement, it was determined that it is currently not feasible to structure the medical problems entered by the physician/PA into the interprofessional and shared patient-centered plan of care due to hospital-wide clinical care dependencies on the existing applications used for problem list documentation. Modifying those existing applications was out of scope of this study. Hence, Figure 1 describes our initial model for working toward patient-centered care planning and conveys the documentation workflows that are feasible for integration in their current state. The Plan of Care and Daily Goals Sheet are included under "RN" in the figure to denote those are conducted by the nurse. The To-Do's and Checklists and Medical Problem List are included under the MD to indicate those are conducted by the Physician. While the Physician To-Do list is informed by the medical problem list and the Nurses Plan of Care is informed by the Daily Goals Sheet we acknowledge that the exclusion of the medical problem list and daily goals for feasibility reasons is not ideal. We envision an ideal future version of a shared patient-centered plan of care that fully integrates the medical problem list and daily goals documentation.

Table 2. Plan of Care Requirements based on Opportunities for Engagement and Current Documentation Artifacts

User	**Residents/Physicians' Assistant Shared Checklists and "To-Do" list**	**Nurses Shared Plan of Care**	**Patient/Family PRGS (Problems, Respect, Goals, Summary)**
User specific Requirements	• Documented during rounds • Structured commonly used "To-Do's" • Ability to free-text To-Dos • Structured checklists • Ability to electronically check off "To-Do" list • Ability to select To-Do's and checklist items to "push" to patient • Future state: integration of medical problem list	• Problem based • Structured problems • Ability to free text problems • Ability to select problems to "push" to patient • Identification of problem-based goals and interventions and status selection for each • Share common checklists with Residents/Physicians' Assistant checklists • Future state: integration of daily goals sheet	• Data Entry of PRGS o Problems o Respect for Preferences o Goals o Summary and Status • Schedule/planned procedures • Home/out-patient medications/therapy regimen
Shared Requirements*	Ability to view and edit Shared Patient Centered Plan of Care • Data pushed from o Nurses Shared Plan of Care o Residents/Physicians' Assistant Shared Checklists and "To-Do" list • Data pulled from Patient PRGS (Problems, Respect, Goals, Summary) • Ability to print • Ability to version • Ability to compare days		
*Shared Requirements pertain to users outlined in table as well as additional care team members such as Attending Physician and Charge Nurse.			

The nurses required the ability to view the plan of care from previous days and carry-over the problem list from shift-to-shift and revise as needed. The nurses shared plan of care documentation included a problem list and a separate system-based structure for the nurse to identifying goals and interventions that addressed each body system. The problem list used nursing terminology consistent with the Clinical Care Classification system, which facilitated the development of structured problems for selection with the ability to include free-text problems. There were a lack of linkages between the problems and daily goals/interventions which posed a challenge to pushing information

from the nursing plan of care to the patient. The nursing plan of care was restructured as a problem-based plan of care to facilitate alignment with the Patient-Centered Shared Plan of Care. Additional requirements included the ability to select the status of goals (Improved, Stabilized, or Deteriorated). Both the residents' To-Do list and Checklists and the nurses' Plan of Care required the ability to save new versions without overwriting old versions, compare past days to current day on the same screen, and print.

Our data indicated that a patient-facing care plan requires the ability for patients and families to identify problems, preferences for care, goals, and provide a summary of feedback about the status of care toward those goals. We coined the term for these requirements as the Patient's "PRGS: Problems, Respect for Preferences, Goals, and Summary/Status". As part of their plan, patients and family want to know the logistics for any planned procedures, such as the need to go to a different location in the hospital for a procedure, particularly in the context of coordinating family visits. This finding validated prior work that found patients wanted to view their daily schedule.[7] Finally, to ensure continuity of their plan, including information about their home and out-patient medications was important to patients. Including their out-patient therapy regimen was particularly important for oncology patients.

We also focused on the role of the attending and fellow physician and the charge nurse in the MICU and Oncology Unit. These roles were observed to actively drive the plan of care forward by focusing care team discussions and activities on the "big picture" (what are the care goals and are they aligned with current interventions and the patients' condition), long term goal clarification, care coordination, patient preferences, and the need for and outcomes of family meetings.

Discussion

This study confirms prior work that nurses and physicians document in silos (paper and electronic), despite engaging in shared and formal conversations at rounds.[15,16,25,26] While it is not possible to conclude that the clinicians interviewed are a representative sample, confirmation of findings with prior work lends confidence that the sample and data obtained are similar to other groups of clinicians in the acute and critical care setting. This study extends beyond describing the silos to a unique workflow analysis of how those silos can be integrated for shared planning. However, with critical clinician input we identified existing plan of care activity and workflow processes that provide feasible opportunities for nurses and physicians to contribute to a shared patient-centered plan of care without significant burden. In this study the distinct differences in documentation structure and concepts completed by nurses and physicians serve as a facilitator to integrate each professions' plan of care documentation into a unified view. The nurses' problem list and goal identification using standard nursing terminology is seen as a patient-friendly method of communicating important risks, clinical states, and conditions to the patient/family. The resident/PA "To-Do's" provide a mechanism of communicating concrete daily action items. The safety and quality checklists could leverage Infobuttons to educate patients about safety and quality care activities that they should be aware of and could help monitor.[27]

The option to develop a shared patient centered plan of care that pulled from the nursing plan of care and physician checklists and To-Do lists is seen as ideal because it does not require redundant documentation by the clinicians and fit with their current responsibilities for documenting plan of care activities. Converting the nursing shared Plan of Care documentation and physician shared "To-Do" Lists and Safety and Quality Checklists to a computer-based version was a requirement, but is endorsed by the clinicians and technically feasible. Converting the clinicians' plan of care activities' documentation to a computer-based format would provide an infrastructure to push structured and semi-structured plan of care concepts from the nurses' and physicians' documentation to the patient and receive structured and semi-structured plan of care documentation from the patient. Future work will focus on the feasibility of integrating the physicians' medical problem list and the daily goals sheet used by individual nurses' to take quick and informal notes of tasks and To-dos.

In our observations, patients and families were not actively engaged in rounds discussions. We also rarely observed the discussion of patient preferences (except for code status), confirming our team's prior work demonstrating the low frequency in which patient preferences are discussed during cardiac critical care and acute care rounds.[24] These practices are opposed to the principals of patient-centered care. However, our interviews confirmed that clinicians aimed to provide patient-centered care, yet believed rounds should be reserved for the clinical care team to discuss the patient case without the patient and family present. This observation raises critical questions: Within a PFCC model and a care setting that requires collaborative and coordinated team-based care for critical care and specialty

patients is there a need for clinicians to preserve formal time for discussion without the patient and family present? Does the acuity of the patient, level of uncertainly of diagnosis and prognosis, and role of teaching rounds influence the need for clinicians to preserve formal time for discussion without the patient and family present? PFCC supports the full inclusion of the patient and family. Further research is needed to understand the clinical process requirements for the interprofessional care team to achieve a shared understanding of the patient's state, plan, and preference if the patient and family continue to be excluded from the rounds discussion. It should be evaluated if the clinical workflow process change to *include* the patient and family in all shared discussions prevents open and efficient communication and disclosure of clinical issues, questions, and clarifications among members of the clinical care team.

Importantly, the attending physician and charge nurse were observed to function in critical roles for engaging the care team and patient in the plan of care, though this may not be reflected in any documentation. The attending physician and charge nurse focused on the "big picture" by challenging the care team to clarify long-term goals of care and validate that those goals were aligned with current interventions, the patients' condition, and patient preferences. Development of a shared patient centered plan of care based solely on the individuals that document plan of care activities will miss care team leaders that may serve as "silent" stewards of a patient-centered plan. It is critical that these roles are able to view and contribute to the shared Patient-Centered Plan of Care.

Limitations

This study is limited to two clinical settings, a MICU and an Oncology Unit in one tertiary care academic institution. Our findings require further validation to determine if they are generalizable to nursing and physician engagement with patients for shared patient-centered plans of care in other critical care and acute care environments. These two units were targeted due to some overlap in patient populations between the MICU and Oncology Unit, specifically for oncology patients that require critical care. This allowed for an analysis of two units with important differences but some known similarities to enable an analysis of standard versus distinct approaches to integrating plans of care based on unique workflows and needs of each unit. The clinical settings in this study did not have a fully integrated EHR. However, to our knowledge most EHRs currently do not have interprofessional plans of care that integrate nurses' and physicians' plans. Therefore, we see utility in our findings for care settings with and without fully integrated EHRs. Finally, our data is based on observations and interviews targeted at nurses, physicians, and patients and did not target all types of clinicians that are members of the care team. Certainly, other types of clinicians provide critical plan of care activities. Further studies should: 1) focus on the role of other members of the care team in planning care in the hospital setting, 2) evaluate opportunities for engagement with patients and families for patient-centered plans of care, and 3) assess the impact of a unified plan of care on the quality and efficiency of communication and ultimately on patient outcomes and quality of patient care.

Conclusion

We found that there are common Plan of Care concepts that should be shared among interprofessional care team members, but data entry requirements appear to require tailoring to fit with workflow, data reuse, and minimize duplication of current documentation. Plan of care activities are distributed among a variety of care processes and formal methods of clinical communication. This distributed nature of planning in the care setting and the distribution of plan of care identification among different members of the care team (professional and patient) require the ability to document plan of care components separately while preserving the ability to unify that data for an integrated shared patient centered plan of care.

Acknowledgements

The authors would like to thank the clinicians who provide ongoing feedback to inform development of a shared patient-centered plan of care. This study is part of the Brigham and Women's Hospital PROSPECT Project, which is part of the Libretto Consortium supported by the Gordon and Betty Moore Foundation.

Abstract

Hospitals are under great pressure to reduce readmissions of patients. Being able to reliably predict patients at increased risk for rehospitalization would allow for tailored interventions to be offered to them. This requires the creation of a functional predictive model specifically designed to support real-time clinical operations. A predictive model for readmissions within 30 days of discharge was developed using retrospective data from 45,924 MGH admissions between 2/1/2012 and 1/31/2013 only including factors that would be available by the day after admission. It was then validated prospectively in a real-time implementation for 3,074 MGH admissions between 10/1/2013 and 10/31/2013. The model developed retrospectively had an AUC of 0.705 with good calibration. The real-time implementation had an AUC of 0.671 although the model was overestimating readmission risk. A moderately discriminative real-time 30-day readmission predictive model can be developed and implemented in a large academic hospital.

Keywords: Predictive Modeling, 30-Day Readmissions, Real-Time, Readmission Risk

Introduction

The affordable care act of 2010 established the Hospital Readmissions Reduction Program, requiring the Centers for Medicare and Medicaid Services to reduce payments to hospitals if the cost of readmission rates at a given hospital exceeded predicted costs[1]. As a result, hospitals, academic groups and independent private organizations have invested substantial resources to reduce readmissions[2]. One area of investment is the identification of patients at high risk for rehospitalization in the 30-days after an index hospitalization in order to enable targeted resource allocation to this population.

Identification of patients at high risk for early readmission using predictive modeling has been well documented in the literature. A 2011 systematic review of 26 validated readmission prediction models concluded that most had poor predictive ability but may be useful in certain settings[3]. Importantly, 23 models could not be implemented early during a hospitalization (i.e. in real-time) because data used in the prediction model was not available until after discharge or not available in a structured form. Three models were identified as usable in real-time [4-6]; however, two were predicting 12-month readmission[5,6], and the other was developed on a small population, 1029 patients with congestive heart failure[4]. Other early readmission prediction models were developed for cardiovascular events [7-12], pancreatitis[13], kidney transplant [14], and to identify avoidable early readmissions,[15] though there is no agreement in the literature on exactly how to define "avoidable." More recently developed early readmission models have improved discrimination, and two reported AUCs of 0.75 [16] and 0.77 [17] However, both models required

data that was not available in real-time at the MGH. We did not find any published 30-day real-time readmission prediction models that could be feasibly implemented at our hospital.

As such, we desired to create a model that included elements that would be commonly available on patients admitted to the hospital at the beginning of the admission and accessible electronically in real-time so that risk identification could begin prospectively early in the hospitalization. We defined *real-time* as being able to calculate the 30-day readmission risk the day after the patient was admitted.

Methods

This project was completed at the Massachusetts General Hospital (MGH). The MGH is an academic hospital with 957 licensed beds with approximately 48,000 admissions and 95,000+ emergency visits annually. Data for this project was extracted from existing databases maintained by the MGH for operational and research purposes. We extracted 45,924 hospital admissions for patients who arrived between 2/1/2012 and1/31/2013; of these, 5,570 (12.1%) were readmissions to MGH within 30 days of discharge. This data was merged with inpatient transactional data, emergency department historical data, billing data, laboratory tests, medication orders, and outpatient appointment history. Data was split 80:20 for developing and validating the predictive model.

Readmissions were identified by the presence of an inpatient record, with a subsequent admission date by the same patient (identified by Medical Record Number) within 30 days of the index admission discharge date. In the event that there were multiple encounters within 30 days of discharge, the readmission evaluated is the first one occurring after discharge. Any readmission can become an index admission if there is another encounter following which occurred within 30 days of the prior discharge. Please note, this only included readmissions to the MGH, and is not the same metric as the publicly reported readmission rates which include readmissions to other hospitals. Moreover, the following exclusions were applied to both the index admissions and the readmissions:

- *From the Index Admission and Readmissions: patients discharged to* rehabilitation and hospice
- *From the Index Admission Only:* discharge status of deceased, left against medical advice, transferred to another short term acute facility, discharged/transferred to a psychiatric hospital
- *From the Readmission Only*: Chemotherapy, radiation, dialysis, Obstetrics (birth/delivery)

We performed a literature review to identify predictors from published models. Then we reviewed the existing data infrastructure at the MGH to determine which variables were available and the "lag" on their availability for a real-time implementation. Two hospitalists and another physician were consulted regularly to provide feedback to identify which variables made clinical sense to be included in the model. The variables were then weighted based on their availability in real-time. We identified 40 variables, and used logistic regression to develop our predictive model. Variables that were not statistically significant or that did not meaningfully

improve the model's discrimination or calibration were removed from consideration. We proceeded iteratively with close consultation with three physicians. We purposely did not use a formal backwards elimination process because our goal was to implement a real-time model and factors other than statistical significance (i.e. resources required to access data in real-time) were essential to our predictor selection process. In addition, we aimed to maintain flexibility to perform data transformations to improve discrimination, calibration, and feasibility of implementation.

The two statistics used to measure the model's performance were the area under the ROC curve (AUC) and the calibration. We calculated the calibration by splitting the data into ten groups of lowest-to-highest risk and plotting the expected-versus-observed outcomes.

After we validated our model, we implemented it in TopCare [18], our hospital's population health management system. Using the developed model, we prospectively calculated the AUC, the calibration, and the 30-day readmission risk probability for all admissions between 10/1/2013 and 10/31/2013.

Results

Based on the data available one year prior to the admission at MGH, we split the derivation dataset into the following categories:

- No History: No prior admissions and no coded Elixhauser Comorbidities[19] from outpatient data
- Has Comorbidity: No prior admissions but at least 1 Elixhauser Comorbidity from outpatient data
- Has Inpatient History: Had at least 1 prior admission to the MGH

We developed three separate predictive models with this data and merged the results back together to calculate the AUC and calibration. The following variables were identified as potentially predictive but were not included because they did not meaningfully improve the final model: age, sex, race, language, insurance, presence of advanced directive, marital status, restraint use, means of arrival, count of emergency department visits, count of no-shows in the past year, count of prior admissions, testing positive for illegal drugs, warfarin, rituximab, oral hypoglycemic agents, oral antiplatelet agents, sotalol, oxycodone, fentanyl, hydrocodone, meperdine, morphine equivalent narcotic dose, sedative use, and presence of an emergency department psychiatric consult.

The following variables were included in the final model (Table 1): unplanned admission (Yes/No); admission source (i.e., physician's office, transfer from long-term care, transfer from rehabilitation or skilled nursing facility, ambulance, walk-in); had a notation of drug abuse (ICD-9 code) or homelessness (internal system flag) or had left against medical advice (identified from prior MGH discharges); count of Elixhauser comorbidities based on inpatient and outpatient ICD-9 codes in the past year; number of inpatient days at the MGH in the past year; insulin (Yes\No); antipsychotic (Yes\No); other medications(Yes\No) (furosemide $\geq$ 40 mg, metolazone, lactulose, cyclosporine, or heparin $\geq$ 3000 units). The list of medications was derived from a list of drugs related to adverse drug events[20] and supplemented with recommendations from the

physician collaborators. Please note, all aforementioned medications were ordered during the patient's index admission.

Using the training data set of 36,462 records, the overall model had an AUC of 0.705 (95% CI 0.697 to 0.713). Odds ratios were calculated for each of the sub-models in Figure 1 and the model factors are illustrated in Table 2. The logistic coefficients were applied to the validation data set of 9,325 records and the model had an AUC of 0.714 (95% CI 0.698 to 0.730) and the calibration is in Figure 2. The model was then implemented in real-time for 3,074 admissions between 10/1/2013 and 10/31/2013. It had an AUC of 0.671 and the calibration is in Figure 3. The breakdowns of the readmission rates by each model variable for the retrospective and prospective validation is in table 1.

Discussion

This project was a practical demonstration of developing and implementing a real-time 30-day readmission prediction model for clinical operational purposes in a large academic medical center. The model was moderately discriminative, and was successfully implemented in TopCare, our hospital's population health management system. The infrastructure now exists at the MGH to notify providers early about patients who are at high risk for readmission within 30-days of discharge.

The AUC of the prospective real-time validation was similar to the retrospective validation. Although the model overestimated the outcome in the prospective validation, we attributed this in large part to the difference between the rates of readmission rates in the two groups (9.23% in the validation set and 12.1% in the derivation cohort). We also identified an issue where bed days in the prior year were being over-represented due to duplicates in the database, resulting in an overestimation of readmission risk.

As we developed and implemented this real-time model, we learned three important lessons essential to a successful implementation of a 30-day real-time readmission predictive model. First, risk scores had to be calculated daily for all inpatients beginning no later than one day after the patients' admission date. The timeliness of this calculation was required because post-discharge interventions associated with reducing readmission had to be planned soon after a patient's admission. As a result, we were forced to exclude many popular readmission predictors including length-of-stay and discharge diagnosis, as those variables are not available upon admission. Second, complexity had to be limited to readily available technical capabilities. For example, we excluded predictors identified using keyword searches because highly accurate

parsing could not be implemented easily. Third, the model had to make sense to hospitalists. Certain hospitalists had trouble believing the validity of the prior implemented model because it did not make sense clinically. We addressed this issue by inviting hospitalists to assist us with the development of the model. The success of the implementation of a real-time model required a fine balance between clinical believability, statistical requirements, availability of real-time data, and technical capabilities.

Limitations: The model was designed with data from a single institution from data for a single year, and may not be replicable at other institutions with different available data sources. In addition, we did not try to determine if a patient was readmitted at a non-MGH institution and are therefore underestimating total readmissions.

Conclusion

A moderately discriminative real-time 30-day readmission predictive model can be successfully implemented in a large academic hospital using existing data. Developers of real-time clinical predictive models need to consider more than the discrimination when developing models. An implementable real-time model balances clinical priorities, statistical requirements, availability of real-time data, and technical requirements.

Abstract

NetWellness is a non-profit web service providing high quality health information. It has been in operation since 1995 with over 13 million visits per year by consumers across the world in recent years. Consumer questions in NetWellness have been answered by medical and health professional faculties at three Ohio partner universities: Case Western Reserve University, the Ohio State University, and University of Cincinnati. However, the resident interface in NetWellness is ineffective in searching existing questions that have already been carefully answered by experts in an easy-to-understand manner. In our previous work, we presented a Conjunctive Exploratory Navigation Interface (CENI) reusing NetWellness' 120 pre-defined health topics in assisting question retrieval. This paper presents a novel semantic-based search interface called Semantic Conjunctive Exploratory Navigation Interface (SCENI), using UMLS concepts as topics. 60,000 questions were tagged by UMLS Concept Unique Identifies (CUIs), with each question allowing multiple possible tags. Using a slightly modified 5-point Likert scale for relevance, SCENI reveals improved precision and relevance (precision: 93.47%, relevance: 4.31) in comparison to CENI using NetWellness' pre-defined topics alone (precision: 77.85%, relevance: 3.3) and NetWellness' resident search interface (precision: 50.62%, relevance: 1.97), on a set of sample queries.

Introduction

Although a substantial amount of consumer health information is available online [1], it is not necessarily easy for general consumers to access such information. For example, a study reported in JAMA [2] by Berland et al. found that accessing health information by use of search engines (e.g., Google or Yahoo!) and simple search terms was not sufficient. Only less than a quarter of links on the search engines first pages of search results led to relevant content.

To improve health information retrieval, we developed a Conjunctive Exploratory Navigation Interface (CENI [3]) for exploring NetWellness [7] health questions with health topics as dynamic and searchable menus complementing lookup search. The efficacy of CENI was evaluated by comparing it with a similar search interface with keyword-based search only, as well as the existing search mode using Google search or NetWellness advanced search. The evaluation was conducted through crowdsourcing, a valuable method for gathering data when human participation is needed. Our crowdsourced evaluation of CENI with a comparative study of search interfaces with anonymous, paid participants recruited from an online labor marketplace called Amazon Mechanical Turk (AMT) showed a nearly 2-1 ratio in preference of CENI for 9 carefully designed search tasks. Participants indicated that CENI was easy to use, provided better organization of health questions by topics, allowed users to narrow down to the most relevant contents quickly, and supported the exploratory navigation by non-experts or those unsure how to initiate their search.

However, a limitation of CENI is that the health topics are predefined, reusing those from NetWellness in order to have a side-by-side comparative study. Now that the effectiveness of the CENI interface has been established, this paper presents our work in using UMLS concept labels as topics, resulting in a semantic-based system called Semantic Conjunctive Exploratory Navigation Interface (SCENI). This way, SCENI shares CENI's benefits in its use of topics as dynamic and searchable menus for consumer health information retrieval and navigation, and in allowing users to quickly narrow down to the most relevant results, without the restriction of a relatively small set of predefined topics.

1 Background

1.1 Unified Medical Language System (UMLS) and MetaMap

The Unified Medical Language System (UMLS) [4], developed by the US National Library of Medicine (NLM), is perhaps the largest integrated repository of biomedical vocabularies. The 2014AA release of UMLS covers over 2.9 million concepts from more than 150 source vocabularies. Vocabularies integrated in the UMLS Metathesaurus include the Systematized Nomenclature of Medicine Clinical Terms (SNOMED CT), Consumer Health Vocabulary (CHV), National Center for Biotechnology Information (NCBI) taxonomy, the Medical Subject Headings (MeSH),

RxNorm, and International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM). UMLS also provides a set of broad subject categories, or semantic types, that allows for the semantic categorization of all concepts. Each UMLS concept has a unique concept identifier (CUI), and is assigned one or more semantic type(s) of the 135 semantic types (e.g., Disease or Syndrome, Body Location or Region).

MetaMap [5, 6], also provided by NLM, is the state-of-the-art solution for the annotation of UMLS Metathesaurus concepts and semantic types. It is available via web access, a downloadable Java implementation (MMTx), an Application Programming Interface (API), and a downloadable version of the complete Prolog implementation of MetaMap itself. MetaMap associates biomedical terms to UMLS concepts and assigns a CUI to every term that it can identify.

1.2 NetWellness

NetWellness [7, 8] is one of the first consumer health websites that has been in existence for 19 years. It is a community service providing high quality, unbiased health information created and evaluated by medical and health professional faculties at Case Western Reserve University, the Ohio State University, and University of Cincinnati. These health professionals include physicians, nurses, pharmacists, dietitians and dentists, and serve as "experts" in NetWellness' popular "Ask an Expert" service. Health questions in NetWellness have been generated by consumers and answered by experts after editorial review to make them readable and understandable to consumers.

NetWellness has over 60,000 consumer questions categorized into 120 health topics. Table 1 shows the top 10 health topics ranked by the number of questions related to each topic. Each question in NetWellness consists of four major components: Health Topic, Subject, Question, and Answer (See Figure 1 for a sample question). Each question is assigned one health topic by a consumer when asking the question. The Subject is the title of a question and usually contains the key topical information of a question. Question provides more details on the subject. Answers are given by an expert in the related health topic area.

Table 1: Top 10 health topics ranked by the number of questions in NetWellness.

Topics	**# of Questions**
Pharmacy and Medications	3802
Ear, Nose, and Throat Disorders	3481
Pregnancy	3209
Children's Health	2827
Myasthenia Gravis	2470
Diet and Nutrition	2335
Women's Health	2310
Eye and Vision Care	2249
Lung and Respiratory	1674
Kidney Diseases	1624

1.3 Conjunctive Exploratory Navigation Interface (CENI)

Since each question is assigned a single topic in NetWellness, this presents an impediment to access health questions through multiple pathways in navigational exploration. In [9], a multi-topic assignment method using formal concept analysis was proposed to categorize a question into multiple relevant topics. It achieved a 36.5% increase in recall with virtually no sacrifice in precision compared to NetWellness' original single topic assignment. Based on the results of the multi-topic assignment approach, a novel Conjunctive Exploratory Navigation Interface called CENI [3] was developed for supporting effective retrieval of consumer health questions using health topics in NetWellness. The effectiveness of the CENI interface was evaluated through crowdsourcing and received a nearly 2-1 ratio of preference compared to two other search modes.

However, CENI is limited in the number of health topics that are adopted from NetWellness' existing ones, which may not represent the best choices of potential health topics. In this paper, we present semantic-based SCENI by mining a relatively large collection of UMLS concepts as health topics and tagging each question with the most relevant topics.

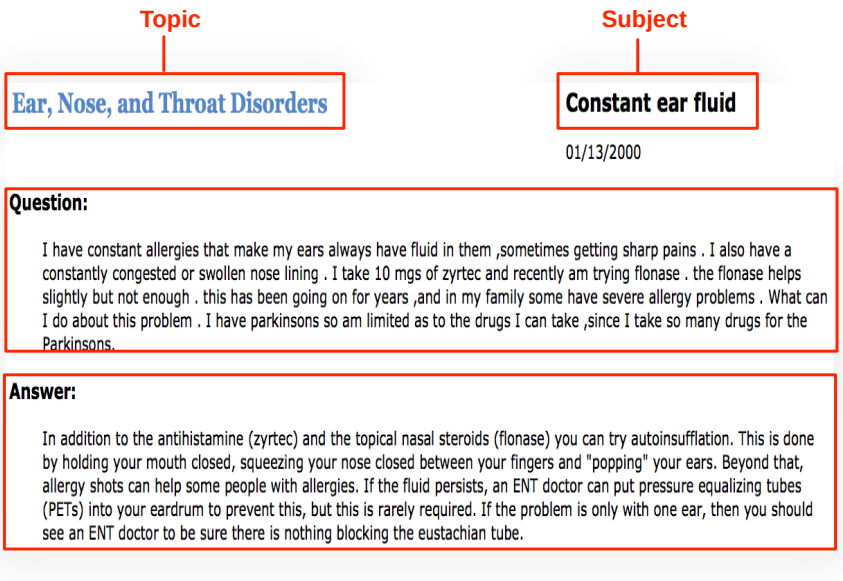

Figure 1: A sample question with the four major components: Health Topic, Subject, Question, and Answer.

2 Methods

Figure 2 depicts the higher level architecture of the proposed UMLS-concept-based tagging approach to facilitating consumer health questions retrieval in NetWellness. First, all the health questions in NetWellness are processed and tagged with UMLS concepts, allowing the handling of synonyms. Second, the most relevant concepts for each question are selected using concept TF-IDF and consumer health vocabulary. Then, resulting concepts for all the questions constitute a concept cloud, which are indexed for retrieving questions in the semantic search interface SCENI.

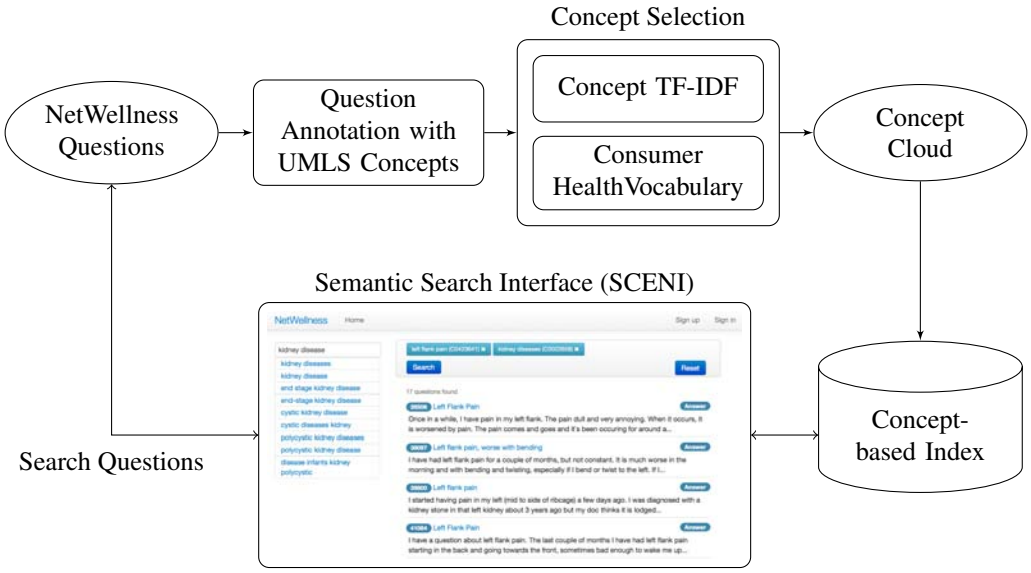

Figure 2: Overview of semantic-based approach to exploring consumer health questions using UMLS concepts.

2.1 Question Annotation with UMLS Concepts

For each health question in NetWellness, the text in its topic, subject and question are processed using MetaMap and mapped to UMLS concepts (CUIs) and semantic types. Since there is a large number of CUIs involved and not all of

them are relevant to consumer heath, we manually identified 31 semantic types that are less meaningful for retrieving health questions, including "Qualitative Concept," "Quantitative Concept," "Intellectual Product," "Regulation or Law," and "Geographic Area." Concepts with such semantic types were filtered out. Moreover, we only consider non-negated concepts in order to remove the noise that negated concepts brought for retrieving related questions based on concepts. After this process, each question is annotated with a set of UMLS CUIs representing the question's relevant concepts. For example, the question shown in Figure 1 is annotated with a set of 15 CUIs shown in Table 2, where each CUI takes the form of "CUI: Preferred concept name," and each number in the parenthesis represents the count of occurrences of the CUI in this question (the parenthesis is omitted if the CUI occurs only once).

Table 2: A set of 15 UMLS concepts annotated for the question shown in Figure 2. The number of occurrences of each CUI is indicated in parenthesis.

C0013447: Ear Diseases	C0028432: Nose Diseases	C0544058: Throat Disorders
C0013443: Ear (2)	C0005889: Body Fluids (2)	C0020517: Allergy
C1881534: Make	C0455270: Sharp pain	C0240577: Swollen nose
C0162723: Zyrtec	C0286677: Flonase (2)	C2945656: Severe Allergy
C0033213: Problem	C0439801: Limited	C0013227: Drug (2)

2.2 Concept Selection

For each question, we select a smaller set of the most relevant concepts adopting the idea of the Term Frequency-Inverse Document Frequency (TF-IDF) metric [10], a most common term weighting scheme in information retrieval and text mining. In this paper, we calculate TF-IDF based on CUIs instead of terms.

Hence the term frequency (TF) for a CUI c in a question q is calculated as the number of occurrences of the CUI in the question and it's topic and subject ($f(c, q)$), normalized by the number of all CUI occurrences in that question ($\sum\{f(w, q) : w \in q\}$), as follows:

$$\text{tf}(c, q) = \frac{f(c, q)}{\sum\{f(w, q) : w \in q\}}.$$

The inverse document frequency (IDF) is used to measure the importance of a CUI c in a corpus of questions Q. It is calculated as the logarithm of the quotient of the number of all questions ($|Q|$) and the number of questions containing the CUI ($|\{q \in Q : c \in q\}|$), as follows:

$$\text{idf}(c, Q) = \log \frac{|Q|}{|\{q \in Q : c \in q\}|}.$$

To avoid division-by-zero, we adjust the denominator to $1 + |\{q \in Q : c \in q\}|$. The TF-IDF weight, calculated as $\text{tf-idf}(c, q, Q) = \text{tf}(c, q) \times \text{idf}(c, Q)$, is used to determine the importance of the CUI c for the question q.

For each question, its top 5 CUIs ranked by TF-IDF weight are selected for tagging the question. We also keep the CUIs identified for the topic and subject of a question, since they contain key information of the question in very short text. Furthermore, CUIs not included in the Consumer Health Vocabulary (CHV) [11, 12] are discarded.

After this process, each question is annotated with a smaller set of CUIs representing the most relevant concepts. For example, Table 3 displays the resulted set for the question in Figure 1. Combining the most relevant CUIs of all the questions with duplicates removed results in a concept cloud.

Table 3: A set of 7 most relevant UMLS concepts representing the question shown in Figure 1.

C0013447: Ear Diseases	C0028432: Nose Diseases	C0544058: Throat Disorders
C0013443: Ear	C0005889: Body Fluids	C0240577: Swollen nose
C0286677: Flonase		

2.3 Concept-based Indexing and Semantic-based Conjunctive Search

The concept cloud is indexed using Picky [13], a Ruby-based semantic text search engine for categorized data. Both CUIs and the strings they represent are indexed to support quick response of concept searching by users. For each health question, the most relevant CUIs obtained after the concept selection process are indexed to support question retrieval using a semantic search interface SCENI. SCENI is implemented in Ruby on Rails and reused the interface design of CENI. SCENI is designed to deal with conjunctive search in a large number of questions and concepts. In SCENI, given a set of concepts to search, their synonyms were also used to better retrieve related questions.

2.4 Evaluation

We evaluated the proposed semantic-based approach in two ways. One is to evaluate if the concept selection process obtains the most relevant concepts for tagging questions. The other is to compare the proposed concept-based conjunctive search with two other existing search modes of NetWellness questions.

2.4.1 Concept Selection

Since no well-established reference standard is available, two experts in health informatics created a reference standard of most relevant concepts for a set of 50 health questions in NetWellness. In [9], a set of randomly selected 300 health questions in NetWellness were used for evaluating the multi-topic assignment method, and resulted in a subset of 278 questions with good quality as the reference standard. In this paper, we randomly chose 50 questions among these 278 and developed a web-based annotation interface for the annotators to review questions and tagging them with the most related concepts. Since it is hard for the annotators to come up with UMLS concepts by themselves, we provided a baseline set of UMLS concepts for each question identified by MetaMap after removing concepts with less meaningful semantic types. The two annotators reviewed the 50 questions together, resolved any disagreements, and created the reference standard.

2.4.2 Semantic-based Conjunctive Search

To evaluate the semantic-based conjunctive search, we designed 5 search tasks (see Table 4) to compare three search modes: the key-word based search in NetWellness official website (NWO) [7], the topic-based conjunctive search in CENI [3], and the proposed UMLS concept-based conjunctive search in SCENI.

Table 4: List of five search tasks.

Search Task ID	Search Task Description
1	Can anti-epileptic medications be taken during pregnancy?
2	Is colon cancer an inherited disease?
3	Is it safe to take birth control pills when breastfeeding?
4	Is it possible to contract HIV from toilets?
5	Can hypertension cause heart attack?
6	Does Keppra cause hair loss?
7	Does drinking alcohol afffect emphysema?
8	What diet would help with gastroesophageal reflux disease (GERD)?
9	What are possible causes of infant sleep apnea?
10	Does toothpaste cause allergy?

For each search task in Table 4, an expert in health informatics used each search mode to retrieve a list of questions, and gave a relevance score for each of the retrieved question using a slightly modified 5-point Likert scale [14], where 0 indicated not relevant at all, and values between 1 and 5 were considered relevant (1 indicated weakly relevant and 5 indicated strong relevant).

3 Results

3.1 Concept Statistics

Over 60000 health questions in NetWellness were processed. MetaMap identified 32195 distinct relevant UMLS CUIs for all questions, their topics and subjects. 23955 CUIs were obtained after filtering out uninformative ones using their semantic types. 21365 CUIs remained left after performing CUI TF-IDF. Removing CUIs that were not in CHV resulted in 18538 CUIs, which constituted a cloud of concepts. Figure 3 displays the top 15 concepts and the numbers of questions they occur in.

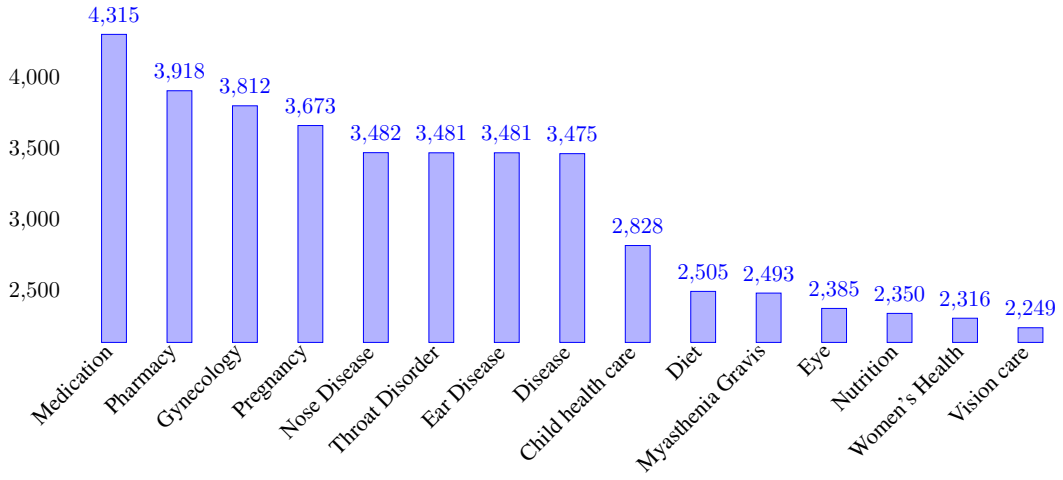

Figure 3: Top 15 UMLS concepts occurring in the NetWellness questions. The x-axis indicates the UMLS concept name, and the y-axis indicates the number of questions each concept occurs in.

3.2 Semantic Conjunctive Exploratory Navigation Interface (SCENI)

The general layout of SCENI interface is illustrated in Figure 4. There are four general areas of SCENI:

1. *Area for searching concepts* allows a user to type a search string into a search box and retrieve concepts of interest among the concept cloud;
2. *Area for displaying candidate concepts matching the search string* lists the matched concepts for a user to select from. Clicking any concept in the list automatically adds a concept tag in the area for displaying selected concepts (red arrow);
3. *Area for displaying selected concepts* shows user-selected concepts. Each selected concept is displayed as a tag in the form of "concept name (CUI)." The "Reset" button is used to start over a new query by clearing the specified concepts;
4. *Area for displaying health questions related to all the selected concepts* is automatically updated when the user clicks a candidate concept, the "Search" button, or the "Reset" button. By default, all questions are displayed if no concept is selected, consistent with convention.

3.3 Evaluation of Concept Selection

To evaluate the results of concept selection, example-based measures for multi-label classification problems [15, 16] were used as the evaluation metrics to avoid a few questions dominating the values of the metrics. Let R be the reference standard consisting of $m = 50$ questions $\{(q_i, Y_i) \mid i = 1, \ldots, m\}$, where Y_i is the set of most relevant concepts tagged for the question q_i. Let Z_i be the set of predicted concepts for q_i. The example-based *precision* (P),

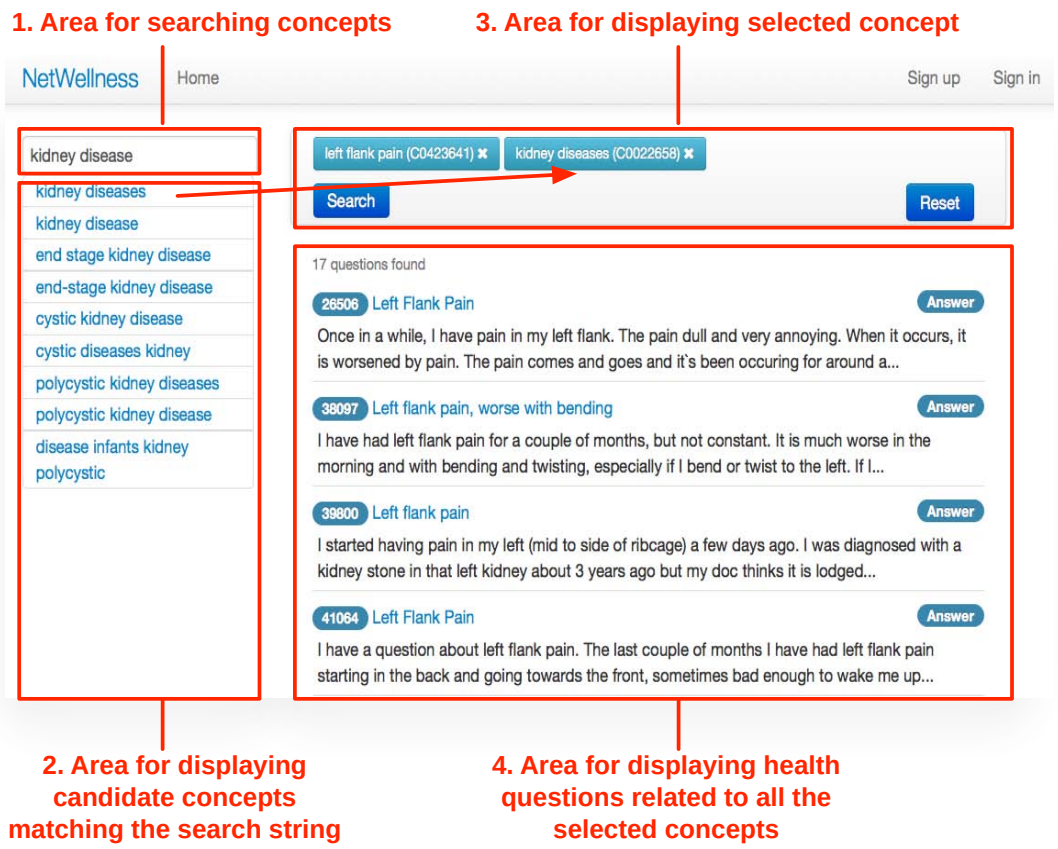

Figure 4: A screenshot of the semantic conjunctive exploratory navigation interface SCENI to retrieve health questions relating to "left flank pain" and "kidney disease." These selected concepts (3. Area for displaying selected concepts) are obtained by typing an unstructured query string into the search box (1. Area for searching concepts) and clicking desired concepts (2. Area for displaying candidate concepts matching the query string).

recall (R) and F_1 *measure* (F_1) were calculated as follows:

$$P = \frac{1}{m}\sum_{i=1}^{m}\frac{|Y_i \cap Z_i|}{|Z_i|},$$

$$R = \frac{1}{m}\sum_{i=1}^{m}\frac{|Y_i \cap Z_i|}{|Y_i|}, \text{and}$$

$$F_1 = \frac{1}{m}\sum_{i=1}^{m}\frac{2|Y_i \cap Z_i|}{|Z_i| + |Y_i|}.$$

Table 5 shows the values of these metrics for the results of three methods: the baseline MetaMap, the TF-IDF method, and the TF-IDF method followed by filtering out concepts not in CHV (TF-IDF + CHV, for short). The TF-IDF + CHV method achieved the best F_1 measure of 0.806, an increase of 40% compared to the baseline MetaMap.

Table 5: The example-based precision, recall, and F_1 measure for the results of concept selection using baseline MetaMap, TF-IDF, and TF-IDF + CHV.

Method	Precision	Recall	F_1
Baseline MetaMap	0.446	1.0	0.576
TF-IDF	0.743	0.932	0.802
TF-IDF + CHV	0.807	0.859	0.806

3.4 Evaluation of Semantic-based Conjunctive Search

To evaluate concept-based search using SCENI, the scores of retrieved questions for search tasks in Table 4 given by the evaluator were used to calculate *precision* and *relevance*. For each search task, precision was calculated by dividing the number of relevant questions (score of 1 or higher) by the number of retrieved questions; relevance was calculated by averaging scores given to each retrieved question:

$$\text{precision} = \frac{\text{\# of relevant questions}}{n}$$

$$\text{relevance} = \frac{\sum_{i=1}^{n} \text{score}_i}{n}$$

where n is the number of retrieved questions. We did not calculate *recall* since it would require the evaluation of each health question in NetWellness for each search task, which is too labor-intensive to perform manually.

Table 6 shows the detailed results of precision and relevance for the two existent search modes (NWO and CENI), and the proposed SCENI. The precision was on average 50.62% for NWO, 77.85% for CENI, and 93.47% for SCENI. The relevance was on average 1.97 for NWO, 3.3 for CENI, and 4.31 for SCENI. This shows the improvement using semantic-based approach.

Table 6: Results of precision and relevance for three search modes of retrieving health questions in NetWellness. NWO: the NetWellness Official website [7], CENI: the Conjunctive Exploratory Navigation Interface in [3], and SCENI: the proposed semantic CENI. Relevance was measured using a slightly modified 5-point Likert scale, where 0 indicated not relevant at all, 1 indicated weakly relevant, and 5 indicated strong relevant.

Query ID	**Precision(%)**			**Relevance (scale 0-5)**		
	NWO	CENI	SCENI	NWO	CENI	SCENI
1	42.86	58.33	87.5	2.14	2.82	4.38
2	22.22	100	100	0.33	5	5
3	33.33	90.91	100	1.11	3.82	3.88
4	0	100	100	0	5	5
5	70	75	88.89	2.5	1.83	2.22
6	100	100	100	4	4.5	4.75
7	33.33	42.86	66.67	1.67	2.14	3.33
8	76	85.71	91.67	2.64	3.79	4.58
9	60	40	100	3	2	5
10	68.42	85.71	100	2.32	2.14	5
Average	50.62	77.85	93.47	1.97	3.3	4.31

4 Discussions

4.1 Performance Analysis

We manually reviewed some health questions and found a number of factors affecting the performance of the proposed semantic-based approach:

1. Spelling errors in health questions. For example, “Larynx” was misspelled as “Larnyx,” and was not identified by MetaMap.
2. Incorrect UMLS concepts identified by MetaMap. Consumers sometimes describe health questions using abbreviations, such as “MG” for “Myasthenia Gravis” and “mg” for “Milligram.” In such cases, MetaMap sometimes incorrectly identify the concept “C2346927: Magnesium Cation” for them.
3. Relatively short description of health questions. Some questions are described in only one or two sentences, which may weaken the advantage of concept selection using TF-IDF and result in less relevant concepts. For instance, for the following question

"If I had a hiatal hernia, would an upper GI series be able to identify it?"

"able" was recognized as the concept "C1299581: Able (finding)" and selected as one of the most relevant concepts due to a small number of concepts identified from such a brief question.

4.2 Limitations

Our evaluation of the semantic-based search SCENI is limited in the number of search tasks performed and the number of evaluators involved in reviewing results. More search tasks and evaluators would avoid bias and provide more statistical power. Since each search task may result in 10s if not 100s of resulting questions, manually evaluating the precision and recall performance is infeasible for larger number of questions. The alternative would be to make the SCENI interface available to the public, with a feedback mechanism built-in the interface. Although this could potentially achieve feedback in scale, it could still introduce biases in feedback responses.

Using UMLS concepts as topics introduces additional challenges. First, concepts with same CUI may have multiple labels which introduces overhead on the interface. On the other hand, terms similar to each other may have distinct CUIs providing an opportunity to apply subsumption reasoning, which we have explored in this work.

5 Conclusion

We have presented a semantic-based approach for exploring consumer health questions using UMLS concepts. SCENI shares the established benefits of CENI without the restriction of a smaller predefined set of topics for supporting menu-driven conjunctive navigation. Our preliminary evaluation shows a slight improvement in precision, and points to the need to alternative forms of systematic, larger scale evaluation.

Semantic Processing to Identify Adverse Drug Event Information from Black Box Warnings

Adam Culbertson M.S., Marcelo Fiszman, M.D., Ph.D., Dongwook Shin, Ph.D., Thomas C. Rindflesch, Ph.D
Lister Hill National Center for Biomedical Communications, National Library of Medicine, Bethesda, MD

Abstract

Adverse drug events account for two million combined injuries, hospitalizations, or deaths each year. Furthermore, there are few comprehensive, up-to-date, and free sources of drug information. Clinical decision support systems may significantly mitigate the number of adverse drug events. However, these systems depend on up-to-date, comprehensive, and codified data to serve as input. The DailyMed website, a resource managed by the FDA and NLM, contains all currently approved drugs. We used a semantic natural language processing approach that successfully extracted information for adverse drug events, at-risk conditions, and susceptible populations from black box warning labels on this site. The precision, recall, and F-score were, 94%, 52%, 0.67 for adverse drug events; 80%, 53%, and 0.64 for conditions; and 95%, 44%, 0.61 for populations. Overall performance was 90% precision, 51% recall, and 0.65 F-Score. Information extracted can be stored in a structured format and may support clinical decision support systems.

Introduction

The prescription drug market in the United States is the largest in the world at $266 billion dollars per year in annual sales in 2010 [1]. These lifesaving drugs help save patients' lives and improve the quality of life for millions, but there are trade-offs. Each year there are as many as two million injuries, hospitalizations, and deaths from adverse drug events (ADEs) [2]. In fact, one study has listed ADEs of hospitalized patients as high as the 4th leading cause of deaths in the United States [3]. Data suggest that patients who experience ADEs spend an average of 8.25% longer in the hospital with greater morbidity [4]. In addition to the higher human suffering, these events lead to a substantial financial cost to an already financially stretched healthcare system. The total cost for ADEs in the United States is estimated at $75 billion annually [2]. The cost savings from these unnecessary tragedies could be invested in other potential cost saving technologies, such as health information exchange.

An adverse drug event is defined by the World Health Organization (WHO) as "any untoward medical occurrence that may present during treatment with a pharmaceutical product but which does not necessarily have a causal relationship with this treatment [5]." An ADE could best be described as an unintended negative outcome that occurs as a result of taking a drug. These could range from rash and hives for a mild reaction to severe reactions, such as respiratory complications or death. Information on the nature of the ADEs caused by a drug is essential in preventing negative outcomes. Furthermore, information that surrounds the ADE such as populations and conditions at greater risk, and what to do in case of an event are also of great importance in preventing the events themselves.

Given the magnitude of adverse drug events on our health care system, one proposed approach to improving efficacy and safety is to make better use of drug safety information. Currently, accurate, relevant, and easy to read drug information is difficult to acquire. Much of the essential information is found in the US Food and Drug Administration (FDA) structured product labels [6]. The labels contain details about pharmacology, warnings, precautions, contraindications, and especially, the black box warnings [7]. However, this information is locked in free text, making its use by automated systems impossible. It would be useful to have this data in a structured format, which would allow access, for example, by clinical decision support systems. Several studies have attempted to extract information from structured product labels using both statistical data mining techniques and natural language processing. However, the scope of these methods is limited in that focus is only on extraction of the actual adverse drug events.

In this paper, we test the feasibility of using SemRep (a semantic based natural language processing system) [8] as a general method to extract information from FDA black box warnings labels, to include adverse drug events, conditions at-risk, and susceptible populations. Our preliminary work on this topic can be found here [9].

Background

Black box warnings

Currently, the US Food and Drug Administration defines and detects adverse events for drugs that are currently on the market. The FDA maintains the Adverse Event Reporting System (AERS), which contains drug-use profiles, population databases, and active surveillance systems [10]. In addition to this knowledge source, the FDA and the National Library of Medicine manage the DailyMed Web site, which currently contains 47,385 drug labels stored in an electronic format known as the structured product label (SPL) [7]. This format is the approved standard of the Health Level 7 (HL7) consortium and has been adopted by the FDA for exchanging product and facility information [11]. The labels include a wide range of information on approved drugs: Description of the drug, Clinical pharmacology, Indications and Usage, Contraindications, Warnings, Precautions, Adverse Reactions, Overdosage, Dosage & Administration, Patient Counseling Information, Supplemental Patient Material, Patient Package Insert, Highlights, Full Table of Contents, Medication Guide, and Black Box Warnings (see Figure 1 for a black box warning example). The information contained in the labels is independently vetted by the FDA when the drug is approved and is considered to be the gold standard for drug information. The FDA can force changes to the labels after the drug is approved, if new safety concerns or information warrant such change. Not all drugs contain black box warnings and this section is one of the most stringent sections of the label and is used for drugs that have the potential for serious adverse drugs events.

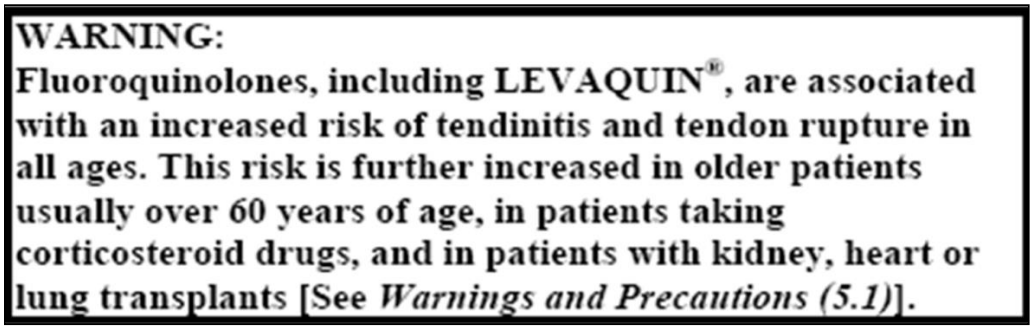

Figure 1. Sample black box warning label for Levaquin® (generic name: levofloxacin.)

Black box warnings include a variety of pertinent information for the prescribing physician. Therefore mining them may have significant clinical impact. Examples of pertinent information include severe adverse drug events, potential susceptible populations such as pregnant women, and conditions that would put a patient at particular risk of adverse events. Given the richness and importance of this information, we chose to analyze black box warning labels.

Automatic methods for identifying adverse drug events

Data mining and natural language processing have been used to extract information about adverse drug events from existing sources of biomedical information. Bates et al. reviewed the research on automatic extraction of adverse drug events. They claim that information technology, especially natural language processing, can be effectively used to identify adverse events in electronic medical records. They suggest that natural language processing will likely become prevalent as new sources of health information continue to become available [12].

Harpaz et al. have explored data mining to discover new adverse drug events[2]. They utilized data-mining analysis and evaluated potential new data sources for ADE discovery such as electronic medical records, administrative claims data, and the biomedical literature. Others have tried knowledge discovery from social media sites. There has been a growing appreciation that social media serves as an innovative method to harness data directly from the consumer. Social media offers great promise as a 'non-traditional source' of data and may serve as an effective tool for the identification of new adverse drug events. One such study by Nikfarin et al. sought to mine the social media Web site DailyStrength for patients self-reporting adverse drug events. They utilized NLP rules-based methods to identify adverse events that may be under reported via traditional methods [13].

Other researchers have focused their attention on SPLs. Rubrichi et al. utilized conditional random fields and compared it to support vector machines for extracting information from SPLs [14]. They sought to automatically extract active ingredient and interaction effects. The work demonstrates the ability of automated methods to successfully pull information from drug labels. Though the paper had promising results, the approach focused only

on the extraction of active ingredient and interaction effects. Fung et al. focused on extracting drug indications from DailyMed [15]. They utilized natural language processing and compared their final results to the national drug file-reference (NDF-RT) and the Semantic MEDLINE Database [16]. The study demonstrates the ability of NLP tools to extract information from SPLs.

Although finding previously unidentified adverse drug events from emerging sources of health data is important, there is still the problem of accessing currently available ADE data from curated sources such as DailyMed. Several research groups have evaluated methodologies to utilize this resource, with a fair amount of success. Bisgin et al. used a topic modeling approach to analyze black box warnings, adverse events, and the warnings and precautions sections of prescription drug labels [17]. They used a statistical hierarchical method. The study produced insight into the connection between various drugs and common adverse drug events such as liver failure and hepatic injury. Another approach was developed by Freidlin and Duke. They created a natural language processing application (SPLICER) to extract adverse events from SPLs. From the output of their system, a standardized ADE knowledge base was created [18]. The system was effective in extracting a total of 534,125 adverse drug events from a total of 5602 product label, with precision of 95% and recall of 93%. SPLICER uses a rule-based and algorithmic approach after adjustments with training data and works in a three step process. It first parses the text, after which the ADE extractor finds patterns likely to contain adverse events. Finally, terms are mapped to the Medical Dictionary for Regulatory Activities (MEDRA). The extracted data is then translated to SNOMED CT codes that can be stored as a value set for clinical decision support. This could lead to better clinical decisions by identifying problematic adverse drug events before the patient receives that drug. The focus of this research is only on adverse drug events; though useful for the clinical decision support, it would be ideal if a knowledge resource contained more general information about the ADE such as at-risk conditions and susceptible populations. Semantic approaches to natural language processing may provide the ability to create a more general approach to extract a broad array of information from structured product labels.

SemRep

SemRep is a semantic natural language system developed at the National Library of Medicine [17]. The system first tokenizes input text and then performs a lexical lookup to the SPECIALIST Lexicon [19]. A parser identifies noun phrases for each sentence, and these are mapped to Unified Medical Language System (UMLS) concepts by MetaMap [20]. SemRep extracts semantic predications which consist of three parts: a subject, an object, and a predicate, which indicates the relationship between the subject and object. For example, from (1) SemRep produces the predication in (2).

(1) Lactic acidosis is a metabolic complication due to metformin.

(2) Metformin CAUSES Acidosis, Lactic.

In addition to CAUSES, SemRep predicates used in this study were PREDISPOSES (identifies risk factors), ADMINISTERED_TO (e.g. “Drug ADMINISTERED_TO PATIENT”), and PROCESS_OF (e.g. “Disease PROCESS_OF Human”). We tested the ability of SemRep to extract information from FDA structured product labels. We focused on black box warnings due to the fact that they are the most serious warning that the FDA issues to drug manufacturers. It is believed that this approach (utilizing semantic predications) can unlock a richer, more generalizable, and deeper understanding of the corpus of drug data than by the many of the previously mentioned methods.

Methods

The DailyMed site housed at the National Library of Medicine provides a rich repository of structured product labels. For this study we only processed the black box warnings of the SPL. Figure 2 gives an overview of the study.

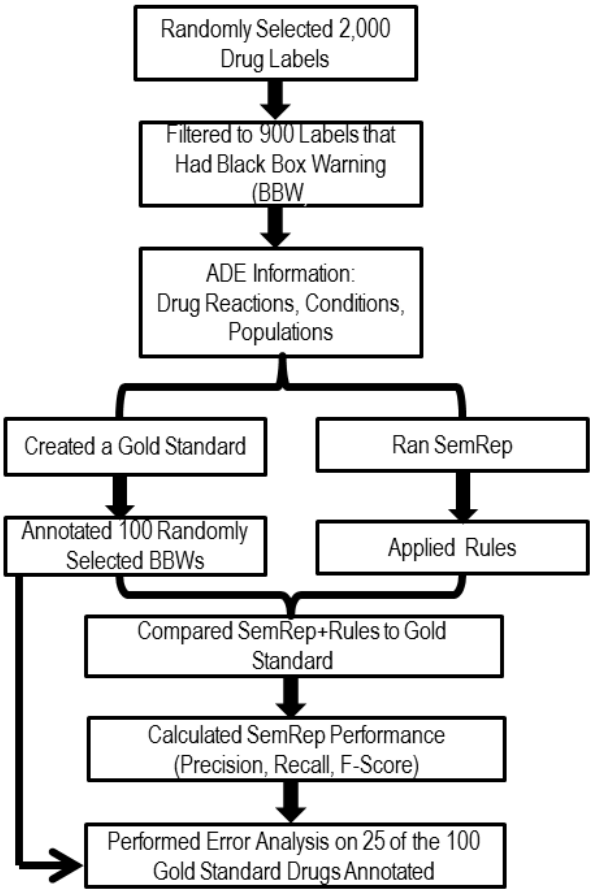

Figure 2. The overall process used to analyze black box drug warning labels with SemRep.

2,000 drug structured product labels were randomly selected from the DailyMed website. Out of those, 900 had black box warnings, which were identified by using the LOINC code 34066-1 (BOXED WARNING SECTION) in the XML text.

We decided to extract three items of information from the free text of the black box warning: the adverse event itself, conditions which put patients at risk for events, and populations at risk for events. These are defined as:

- Adverse event: An adverse event to the drug. (e.g. "Lactic acidosis is a metabolic complication due to metformin.")
- Condition: Disorders which put the patient at greater risk for adverse events. (e.g. "Patients with cardiovascular disease may be at greater risk…"
- Population: Groups at greater risk for an adverse event. (e.g. "Pregnant women should not receive methotrexate.")

Rules applied to SemRep output

Three rules were developed to systematically extract the three items of information from SemRep predications:

1. Adverse event: Object of CAUSES OR Object of PREDISPOSES

2. Condition: Subject of PROCESS_OF

3. Population: (Object of ADMINISTERED_TO OR Object of PROCESS_OF) IF the object Concept is not general, such as "Patient" "Individual," and "Personnel"

1. To identify adverse events, objects of "CAUSES," or objects of "PREDISPOSES" were exploited. An example for the event category is "Lactic acidosis is a metabolic complication due to metformin." The predication extracted from the sentence output was "Metformin CAUSES Acidosis, Lactic." Lactic acidosis, as the object, was retained as an adverse event.

2. To identify conditions, subjects of PROCESS_OF were retained. For example, from the text "Patients with cardiovascular disease may be at greater risk…," SemRep extracted the "predication Cardiovascular Disease PROCESS_OF Patients." Since "Cardiovascular Disease" is the subject, it was retained as a condition for which the drug would put a patient at a greater risk of an adverse event.

3. To identify the population, the object of PROCESS_OF was retained, if it was not "Patient," "Individual," or "Personnel." This was done because these concepts are not specific enough to identify a (useful) population that would be at greater risk for taking the drug. For example, the predication "Acidosis, Lactic PROCESS_OF Pregnant Women" was extracted from the text "Fatal lactic acidosis has been reported in pregnant women", "Pregnant Women," as the object of PROCESS_OF, was retained as an at-risk population.

Evaluation

To build a gold standard, we used 100 randomly selected black box warnings from the 900 extracted from the DailyMed website. The second author (MF) identified at-risk conditions, adverse events, and susceptible populations manually in each of these 100 warnings. We ran SemRep on the same 100 warnings and the rules described above were applied to the output to automatically identify at-risk conditions, susceptible populations, and adverse events. Output from the system (SemRep + rules) was then compared to the gold standard. Performance metrics were calculated for conditions, adverse events, and populations using precision, recall and F-Score.

Results

The results demonstrated that SemRep performed well as a novel tool to identify information from black box warnings (Table 1). Precision was 95% for susceptible populations, with recall 44%, and an F-Score of 0.61. For at-risk conditions, precision was 80%, recall was 53%, and the F-Score was 0.64. For adverse events, precision was 94% with recall of 52%, and F-Score of 0.67.

Table 1. Performance metrics on the ability of semantic processing to extract information from FDA black box warning labels. N = Total number of instances.

	Condition	Population	Adverse event	Overall
Precision	80%	95%	94%	90%
Recall	53%	44%	52%	51%
F-Score	0.64	0.61	0.67	0.65
N	84	83	317	484

Discussion

Results were promising in this study to determine the feasibility of using SemRep and post-processing rules to extract adverse event information (including susceptible populations and at-risk conditions) from black box warnings. Since recall was lower than precision, we performed an error analysis concentrating on the false negatives. Twenty-five random false negatives were analyzed. The most common error type was due to anaphora. Information needed for its resolution often does not appear in the sentence being processed. The following text provides an example.

"*Only physicians experienced in immunosuppressive therapy for organ transplant patients should prescribe Cyclosporine…The drug increased susceptibility to infection and the possible development of lymphoma."*

In order to resolve the sortal anaphoric element *the drug*, SemRep would require access to its antecedent *cyclosporine* in the preceding sentence, which it currently does not have. A future version of SemRep will have the ability to resolve this type of anaphora.

A second common cause of error was that some semantic interpretation depends on inferencing, as in the following sentence:

"There are serious and life-threatening events associated with tamoxifen. Uterine malignancies consist of both endometrial adenocarcinoma and uterine sarcoma."

In order to determine the adverse events associated with tamoxifen, it is necessary to infer that uterine malignancies and endometrial adenocarcinomas are life threatening. This is a challenging problem for natural language processing, which SemRep does not address.

Since precision was lower for at-risk-conditions, we also looked at false positives in this category. The method uses a simple rule to extract conditions-at-risk with the assumption that in the black box warnings the subjects of PROCESS_OF would be mostly these conditions. In spite of 80% precision, there were eleven false positives where the condition mentioned was not the condition-at-risk, but an indication of the drug. The following sentence provides an example.

"Fluvoxamine Maleate Tablets are not approved for use in pediatric patients except for patients with obsessive compulsive disorder"

In this case, the antidepressant fluvoxamine can be used in children with obsessive compulsive disorder. The rule erroneously extracted obsessive compulsive disorder as condition-at-risk.

The ability of a natural language processing system to extract adverse events, but also other types of information, from black box warnings, such as susceptible populations and at-risk conditions is essential for clinical applications such as clinical decision support systems. The information extracted from black box warnings and stored in structured format can be matched against the electronic health record and prevent serious adverse events. For example, if a clinician is considering prescribing an angiotensin-converting-enzyme inhibitor such as enalapril for a patient who is pregnant, information extracted from the black box warning (i.e. Drug: enalapril, Population: pregnant women, Adverse event: fetal death), could provide an alert concerning the serious potential consequences.

Given the number of patients affected by adverse drug events, there is a need to produce general structured data that can be used to provide clinicians, patients, and informatics applications with readily accessible information. It would be particularly valuable to have accurate, up-to-date information for clinical decision support systems available to the clinician at point of care. This could be accomplished by giving the clinical decisions support tool access to the data from drug warning labels that would, for example, help physicians identify patients most at risk for adverse events, especially those with relevant preexisting conditions.

In the future, we would like to expand the information that we extract from black box warnings beyond populations, conditions, and adverse events. Information such as what to do in the event of an adverse event, contra-indications, warnings, precautions, and drug dosage would all be useful expansions to the current research. It is likely that writing rules that apply to SemRep output, and that capture this additional information, will be straightforward. Additionally, we would like to process the entire corpus of prescription drug labels on the DailyMed site. Lastly, we need to modify SemRep to address the linguistic errors identified in the error analysis.

Limitations

This study has limitations. First, the sample size for analysis was rather small with 100 labels evaluated. It remains to be seen how the performance of the system will scale in the larger set of 900 labels that we currently have identified. Second, the gold standard was created by one physician who has experience with SemRep. It would be ideal if physicians not involved in natural language processing system were involved in gold standard creation. Finally, we did not compare our methods to other approaches (i.e. statistical and machine learning), since in this exploratory study our major objective was to determine the feasibility of a rule-based approach.

Conclusions

Having reliable automatic access to drug and prescribing information from FDA package insert labels provides notable benefit to health care. Such access would likely translate into better health care, fewer deaths, and fewer adverse events to prescription drugs. While previous approaches such as topic modeling showed promise to evaluate package insert labels, the additional information available in semantic search technologies will likely underpin significant improvements to mining drug labels. Overall, SemRep was useful as a novel tool to extract information from FDA black box warning labels. The lower recall of the system was largely due to deficiencies in anaphora resolution and the challenging problem of inferencing.

Information Requirements for Health Information Exchange Supported Communication between Emergency Departments and Poison Control Centers

Mollie R. Cummins, PhD, RN, FAAN, Barbara I. Crouch, PharmD, MPH, Guilherme Del Fiol, MD, PhD, Brenda Mateos, Anusha Muthukutty, MS, Anastasia Wyckoff, MA
University of Utah, Salt Lake City, UT, USA

Abstract

We analyzed audio recordings of telephone calls between emergency departments (EDs) and poison control centers (PCCs) in order to describe the information requirements for health information exchange. Analysis included a random sample of 120 poison exposure cases involving ED-PCC communication that occurred during 2009. We identified 52 information types characterized as patient or provider information, exposure information, ED assessment and treatment/ management, or PCC consultation. These information types constitute a focused subset of information that should be shared in the context of emergency treatment for poison exposure. Up to 60% of the information types identified in the analysis of call recordings can be represented using existing clinical terminology. In order to accomplish standards-based health information exchange between EDs and PCCs using data coded according to a standard clinical terminology system, it is necessary to define appropriate terms, information models and value sets.

Introduction

Poison control centers (PCCs) routinely collaborate with emergency departments (EDs) to provide care for poison exposed patients. Of approximately 2.3 million poison exposures reported to U.S. PCCs in 2012, 27% were managed in a healthcare facility.[1] The PCC and ED share information about the patient, the patient's status, and circumstances surrounding the poison exposure throughout the ED visit. As poison exposure cases evolve, the PCC and ED are in regular communication via telephone for the purpose of collaborative care planning and on-going consultation.[2] The ED care providers verbally share clinical information with a PCC specialist, including patient symptoms, general condition, and the results of certain laboratory tests; the PCC frequently updates treatment recommendations as additional information becomes available. Multiple handoffs can occur for both the PCC and ED.[2] Information may be communicated to one or multiple ED care providers depending on the workload in the ED and the status of the poisoned patient or other patients in the ED. Crucial information documented during this complex process remains isolated within the respective information systems of the ED and PCC and is not shared across organizational boundaries.

In preliminary studies, we found that the current process of telephone-based communication and information sharing between emergency departments and poison control centers is vulnerable to miscommunication, data loss, and error.[2] Examples of safety vulnerabilities include: difficulty establishing synchronous verbal communication via telephone, discussion of multiple patients during the same telephone conversation, and communication with non-clinical staff members.[1] Additionally, any information moved among patient care settings via phone may or may not be documented for continued use by the recipient health care facility. Verbal communication, though expressive, is fraught with pitfalls that affect patient care.[3,4]

The current process of telephone-based communication is also vulnerable in disaster scenarios. PCCs manage calls from *both* public and health care providers, and routinely see increases in call volume due to infectious disease outbreaks and other non-poisoning public health concerns. A process based solely on verbal, telephone communication is fragile. Studies of poison control center operations during call surges are scarce. However, in a previous study, we found that even routinely encountered busy times tax the ability of PCC specialists to communicate.[5] A 2007 article by Vassilev and colleagues describes an incident in which a poison control center experienced compromised operations due to an unexpected 148% increase in call volume.[6] In the setting of mass scale poisonings due to natural disasters, accidents or terrorism, a system based entirely upon telephone communication is fragile.

Given existing technology to support the electronic exchange of data and information across organizational boundaries, there is potential to reduce medical error, reduce time to treatment, and improve continuity of care through a more efficient and structured process of ED-PCC collaboration. In order to design a more robust, structured process for ED-PCC collaboration, supported by health information exchange, it was necessary to determine and characterize the information requirements We analyzed audio recordings of current telephone-based communications between EDs and PCCs in order to describe the information requirements for health information exchange between poison control centers (PCCs) and emergency departments (EDs). Our goal was to identify a focused subset of available health information, most relevant to emergency treatment of poison exposure, in order to support generalizable process re-design. The first research assistant analyzed the transcripts, creating a formative list of information types evident in the communication.

Methods

Setting. We conducted the study at a single poison control center in the intermountain west. The poison control center has a very high utilization rate compared to national data, and so it constitutes a rich source of data describing interactions between PCCs and EDs. In 2011, the poison control center managed 42,544 human poison exposures, with approximately 13% of cases managed in the emergency department setting and entailing collaboration between an emergency department and the poison control center.

Sample. We used a saturation sampling approach, based upon an initial random sample of 500 poison exposure cases, managed in the emergency department setting and involving ED-PCC communication, during the calendar year 2009. As described in Cummins et al (2013), we sequentially analyzed the calls until we failed to identify new information types in 40 additional, randomly selected cases.[2] This saturation sampling approach ensured an adequate sample size to describe the types of information routinely shared in ED-PCC communication, while conserving the resources necessary to analyze calls and minimizing the use of patient data. Ultimately, we analyzed calls corresponding to a sample of 120 poison exposure cases.

Data Preparation and Analysis. As described in Cummins et al (2013), telephone calls between the poison control center and its collaborating EDs are routinely recorded and stored on a secure server, and we previously developed a process for linking cases to analog call recordings.[2,7] We applied this procedure in 20 case increments according to the saturation sampling plan, linking calls to cases as necessary until saturation was reached. For each 20 case increment used in the analysis, we linked call recordings to cases, verified the linkage, exported the call recordings, and converted them to digital format. We transcribed the call recordings and removed identifiers of personnel, patients, and health care facilities. Two research assistants, graduate students in biomedical or nursing informatics, analyzed the data. The first research assistant analyzed the transcripts, creating a formative list of information types evident in the communication. The second research assistant independently reviewed the transcripts, in order to validate the information types. Questions or difficulties in conceptualizing and categorizing information types were resolved through discussion by the research team, and in cases of disagreement, the principal investigator made final determination. Given the lack of pre-determined concepts and categories, this process was formative and iterative. This process resulted in a list of information types and the frequency of their occurrence per poison exposure case.

Representation in Clinical Terminology and Coding Systems. A research assistant manually searched for inclusion of each information type in existing clinical terminology or coding systems, with review and supervision by the principal investigator. These systems included AAPCC (American Association of Poison Control Centers) substance codes, CPT (Current Procedural Terminology), ICD-9 and ICD-10 (International Classification of Diseases, Ninth and Tenth Revisions), NDC (National Drug Code), RxNorm, Poisindex, SNOMED-CT (SNOMED Clinical Terms), LOINC (Logical Observation Identifiers Names and Codes), DEEDS (Data Elements for Emergency Department Systems) 1.0, and NPDS (National Poison Data System).[8,9,10,11] Information types were insufficiently granular for precise mapping at the concept level, but the capability to represent each information type could be assessed. In these cases, the principal investigator reviewed the nature and scope of each terminology system with respect to the information type, and determined whether the system could be used to represent the information type.

Results

Identification of Information Types. We reached sampling saturation upon analysis of calls corresponding to 120 cases. Inter-coder disagreement was infrequent and resolved through team discussion and review of transcripts. The research team reviewed the information types, and where appropriate, aggregated duplicate or nested concepts. After validation and aggregation, we identified 52 information types listed and categorized in table 1. The information content of analyzed calls included essential identifying information – information identifying both

health care provider (location, type of provider, name) and patient (name, age, gender). It also included essential health information about the patient, including current medications, allergies, and health history. Many information types described the poison exposure incident. Information was exchanged about the poison, its characteristics and effects, and clinical treatment. Information was also exchanged about the poisoning scenario, including important circumstances that bear upon decision making related to care of the patient.

Narrative information, the poisoning "story", included details important for discerning whether the poisoning was intentional (overdose or suicide attempt) or unintentional, and details that help to establish the certainty, dose, and timing of the exposure. As a fictional example, a narrative might include a description of the parent's estimate of the number of tablets remaining in a full prescription bottle, and the time at which a child was found eating tablets from that open bottle. Both the PCC and ED collected and shared these types of information. The ED care providers, who assess the patient in person, shared information about the physical exam and appearance of the patient, clinical findings, and the results of any diagnostic testing. They also shared information about the patient's plan of care, and treatment or management. The poison control center, acting as consultant, provided feedback on clinical findings as well as treatment and monitoring recommendations. This frequently entailed general communication about the type of poison, its characteristics, effects, and treatment in a type of communication that appears to establish common ground for the discussion of the specific patient and exposure at hand. Communication also frequently included requests for information from the other party.

Table 1. Types of information shared during telephone calls between EDs and PCCs, excluding patient/ provider identifying information.*

Exposure information	
Exposure Type	E.g., polypharmacy, accidental, overdose.
Certainty of Formulation	In a circumstance where the poison is a therapeutic agent, the level of certainty about the precise formulation, based on the subjective/ objective information provided.
Chronicity	Duration of exposure (acute vs. chronic)
Establishing background/certainty	Narrative information about the poison exposure scenario specifically relevant to determining the certainty of ingestion/exposure, and general information helpful in constructing a clinical picture of the patient and treatment plan.
Substance class	General grouping or characterization of poison (e.g., beta-blocker)
Substance information	General characteristics of a poison (e.g., half-life, mechanism of action, peak effect)
Substance name (generic)	Generic name of poison that is also a therapeutic agent
Substance amount	Dosage or amount of substance (e.g., 500mg metformin)
Substance name (brand)	Brand name of poison that is also a therapeutic agent
Substance description	Informal description ranging from general class of drug (e.g., antiarrhythmic) to intended purpose (e.g., a chemical used to clean carburetors)
Substance form	E.g., tablet, pill, powder, lozenges.
Substance formulation	E.g., extended release vs. Rapid release
Substance identification rationale	Narrative describing reasoning of PCC specialist in identifying a substance based on described characteristics of the poison (e.g., "A blue pill in that shape can be a few different things, but it is probably Viagra")
Substance-nonpharmacological	Name of non-pharmacological substance
Substance type	E.g., solid, inhalant, liquid.
Time since ingestion	Amount of time elapsed since initial poison exposure (e.g., "It has been about 5 hours since she took the pills.")
Patient health history	
Medical history	Information about patient's past medical history.
Patient medications	Medications that the patient currently takes at home.
Subjective & objective Information	
Chief complaint/ reason for	Patient's chief complaint upon presenting to emergency department or

visit	calling poison control center.
Absence of clinical effects	The absence of any signs or symptoms attributable to poison exposure.
Mental status	Information about patient's mental status.
Caller reported symptoms	Symptoms as reported by patient or caller to PCC.
Physical exam findings	Signs observed by ED health care providers.
Unrelated symptoms	Health care provider or PCC assessment that a symptom is unrelated or likely unrelated to the poison exposure. For example, a patient may exhibit tremors related to underlying Parkinson's disease, unrelated to an acute narcotics overdose.
Vital signs	Information describing patient's blood pressure, heart rate, and/or respiratory rate along with the time the vital signs were obtained.
PCC recommendations &toxicology information	
PCC recommendations for treatment and discharge parameters	PCC recommendations for treatment and/or duration of direct observation prior to discharge from the ED.
Toxic dose	Specific dose or amount of exposure, at which a substance becomes toxic.
Toxicity levels	Circulating blood level of a substance considered toxic.
Clinical effects of substance	Potential or expected clinical effects of a given poison exposure.
Worst case scenario	Description of the most harmful clinical effects and poorest outcome that patient might experience (a description of risk), usually PCC to ED.
ED treatment / management information	
Confirmation that was treatment given	ED staff member indicates whether or not a PCC recommended treatment has been administered to a patient.
Patient discharge medications	Medications prescribed for patient at time of discharge from ED.
Patient status	ED description of patient's clinical condition, particularly whether clinical effects of exposure are observed.
Plan of care	Refers to ED health care provider plan of care for patient (e.g., treatments, procedures, length of stay, parameters for discharge).
Diagnostic test results	Inquiry about results of diagnostic tests (e.g., laboratory, ECG, imaging).
Time next laboratory tests will be ordered	Information about the ED's planned or recommended timing of subsequent diagnostic testing (e.g., "We'll get another level at 4 hours [after ingestion].").
Time laboratory test was performed/drawn	Information about the timing of a treatment or a lab test, usually in relation to the time of ingestion (e.g., "That level was drawn 2 hours after ingestion").
Treatment performed	Information that a treatment, directly related to the poison exposure, was administered.
Information types idiosyncratic to telephone communication	
Ambiguous Test Result	Characterization of the results of laboratory or non-laboratory diagnostic testing
Confirmation Patient Arrived at Hospital	Confirmation by an ED staff member that a given patient is under the care of that ED
Request for Chronicity	Inquiry about duration of exposure
Patient Status Request	Inquiry into patient's status, both clinical condition and whether the patient is still under ED care
Request for clinical effects information	PCC inquiry as to clinical effects effects observed by ED health care provider
Request for Lab/Test Results	Inquiry as to results of laboratory diagnostic testing
Request for Test Results	Inquiry as to results of non-laboratory diagnostic testing

*PCCs collect information for entry into the National Poison Data System (NPDS) and consequently, some information types resemble NPDS data elements. However, NPDS data elements are defined differently, as described in a published coding manual.[11]

We compared these information types to commonly accepted clinical terminology and coding systems using the UMLS Metathesaurus, terminology browsers or coding manuals. In this preliminary screening, none of the terminology systems provided complete coverage of the identified information types. NPDS (National Poison Data System) represented 38/52 information types (73%). Clinical terminologies LOINC and SNOMED-CT represented approximately half of the information types. A specialized set of data elements designed for the emergency department setting (DEEDS), represented 31/52 information types (60%). See figure 1 for results. In figure 2, we show the categories of information types along with the coding or terminology systems that best represented the information types within those categories.

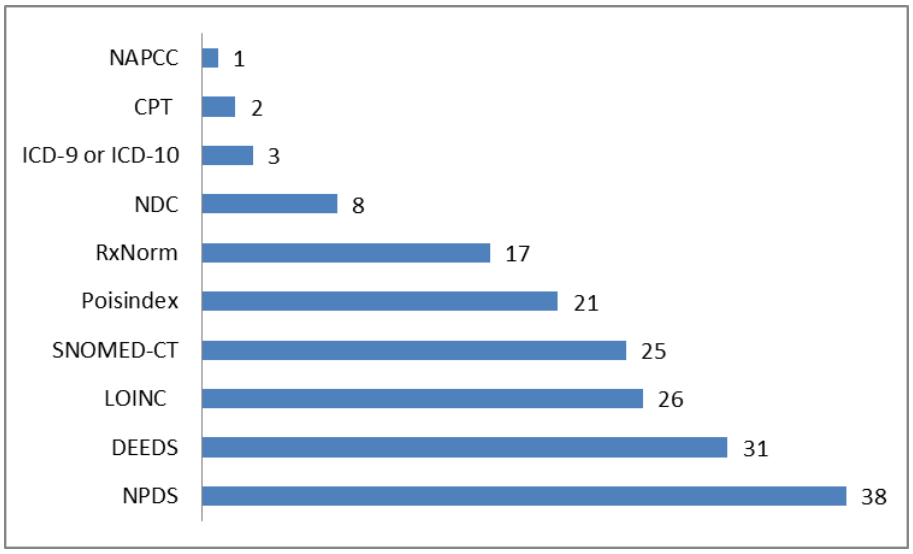

Figure 1. Representation of information types by commonly accepted clinical terminology and coding systems.

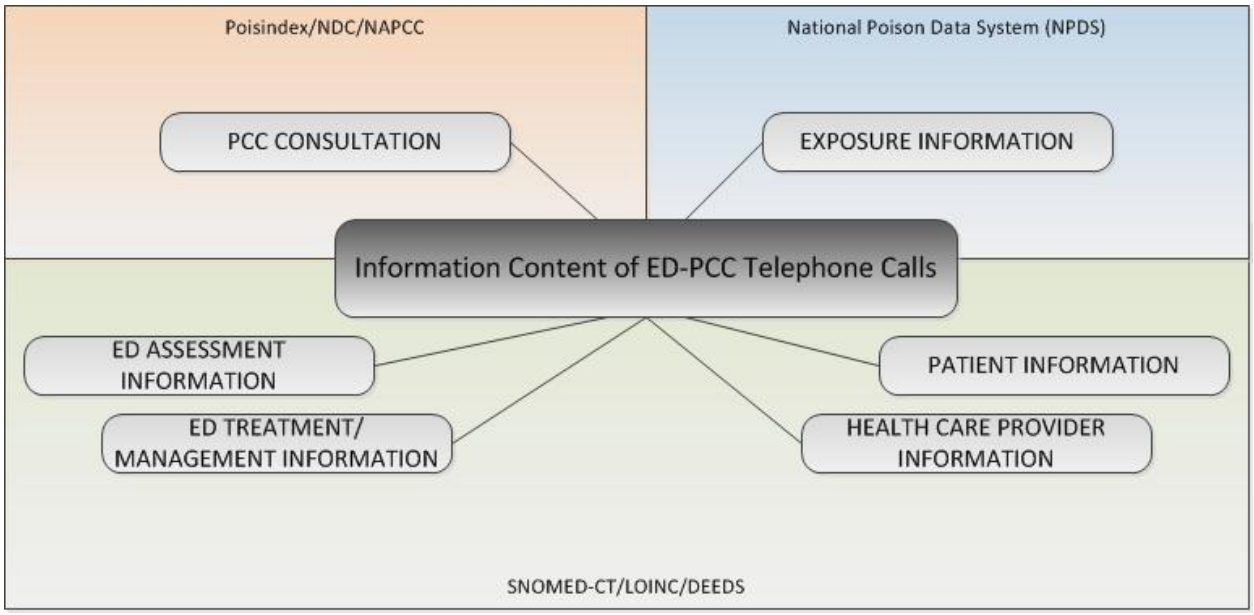

Figure 2. Terminology coverage of information types used in ED-PCC communication.

Discussion and Implications

Approximately 50-60% of the information types identified in the analysis of call recordings map to the widely used clinical terminologies LOINC and SNOMED-CT, and a specialized set of data elements designed for the emergency department setting, DEEDS. However, many of the identified information types are highly specialized to the context of poisoning scenarios and are not found in standard clinical terminology systems. ED-PCC communication about poison exposed patients involves types of information that are not commonly represented in standard clinical terminology systems. In order to accomplish standards-based health information exchange using data coded according to a standard clinical terminology system, additional terms must be proposed and adopted.

The National Poison Data System (NPDS) data elements mapped most successfully to the information types. However, NPDS is structured to support case-level data vs. patient-level data, and is not structured as a clinical terminology. NPDS data elements were designed for the purpose of surveillance and not to support clinical information systems or patient care. Although used by all U.S. poison control centers, NPDS data elements are not currently mapped to any standard clinical terminology system and preliminary attempts at mapping have yielded disappointing results, so they do not facilitate interoperability with emergency departments.[12] Moving toward interoperability, it is important to create a mapping of NPDS data elements to standard clinical terminology systems or expand existing clinical terminologies. It is also necessary to identify standard information models (e.g., CDA) that would be used to instantiate the standard codes, since those codes need to be bound to slots in standard information models. Standard value sets (allowed set of codes for a given data element) should be used in the standard information models, and the NLM (National Library of Medicine) value set authority center could be used as the central resource for submitting and managing these value sets.

Representing Information Content with Existing Clinical Terminology and Coding Systems. One key challenge in designing a health information exchange supported collaboration process, particularly in the context of an emergency poisoning event, is to focus attention on information immediately relevant to the health event and decision making at hand. In the context of ED-PCC collaboration to care for poison exposed patients, we identified 52 information types that should be addressed in the design of health information exchange activities. However, it is currently not possible to represent all of these information types using standard clinical terminologies.

Patient and Health Care Provider Information. Basic information about patients and health care providers (name and gender, for example) is commonly collected in health care settings, and so it is commonly included in standard clinical terminologies and standard clinical information models. Similarly, information about health care providers can be represented using multiple clinical terminology systems and information models.

Emergency Department information. ED assessment information, including the initial history & physical examination and subsequent clinical observations, can be represented using concepts found in DEEDS (Data Elements for Emergency Department Systems)/ LOINC and SNOMED-CT. Similarly, ED treatment or management information can be described using concepts found in DEEDS/LOINC and SNOMED-CT. DEEDS is a terminology system designed to support emergency department operations, and closely fits the type of assessment and observational data exchanged in ED-PCC telephone calls. DEEDS is included in LOINC, a much larger clinical terminology system.

Exposure. Exposure information closely matches NPDS data elements, a logical circumstance given that collection of these data elements is one purpose of the telephone calls. To some extent, these information types can also be represented using DEEDS/ LOINC. However, the coverage of exposure information by DEEDS/LOINC is incomplete or insufficiently granular. This is not surprising, given the highly specialized nature of poison control center operations. PCCs collect information about poison exposure at a much more granular level of detail, a level of detail that supports surveillance and public health intervention. NPDS is case-based, collected for the purpose of surveillance, and NPDS data elements are not structured as a clinical terminology. New information models such as CDA templates would need to be created to represent PCC exposure information.

Substance. Substance information can be represented using several terminology or coding systems. However, the nature and extent of information varies. Poisindex, a proprietary, subscription-based toxicology database, best matches the depth of information shared in telephone calls between EDs and PCCs. Poisindex codes are currently used to identify a very specific type, brand, and formulation of a substance, pharmaceutical or non-pharmaceutical. NAPCC substance codes are also currently used to characterize the type of substance in a meaningful way from the perspective of poisoning epidemiology. Drugs manufactured for therapeutic purposes are often involved in poisoning and if the poison is a manufactured therapeutic agent (Vicodin, for example), it could be

coded using NDC or RxNorm. However, many poisonings involve naturally occurring substances not indexed in NDC or RxNorm (snake venom or toxins from wild mushrooms, for example). Many more poisonings involve inhaled gases (e.g. carbon monoxide), illicit recreational drugs, industrial chemicals, household cleaning agents, and other non-therapeutic chemicals not indexed in NDC or RxNorm. A specific value set for substances could include a subset of RxNorm codes (e.g., ingredients and branded drugs) and a combination of codes from other non-drug terminologies. Additionally, these codes must be used in a way that clearly establishes the context as poison exposure vs. pharmacotherapy.

Limitations

The findings of this study are observational in nature, describing information that is currently shared using telephone communication. In current process re-design efforts, we are obtaining clinician input about additional, potentially helpful information types as well as prioritization of information types. As a single site study, the findings possibly include some information types that are idiosyncratic to the region (intermountain west) or poison control center and emergency departments studied. However, the communication process used by this poison control center is highly similar to the process used by other U.S. poison control centers, and the specific information types found in this study appear to reflect universal aspects of emergency care for poison exposure. Consequently, the findings provide a reasonable basis for standards development and process improvement efforts. Comparison of information content according to ED characteristics was outside the scope of this study. However, the emergency departments served by the poison control center are diverse and include both small, rural hospitals and urban academic medical centers. Additionally, information content may also have varied during surge conditions.[5] The primary purpose of our study was to inventory information types, and the presence of an information type in a single transcript was sufficient for inclusion in the inventory.

Conclusion

Given evidence of inefficiencies and safety vulnerabilities in the current telephone-based process of ED-PCC communication and information sharing, new models of collaboration must be considered. We are currently developing a health information exchange supported collaboration process, designed to support dynamic, real time, bidirectional communication between EDs and PCCs to support care of poison exposed patients. This study identified the subset of health information that should be included in such a process. Moreover, the results indicate that telephone-based communication about poison exposed patients entails the sharing of information types that are not currently represented in standard clinical terminology systems. In order to accomplish standards-based health information exchange between EDs and PCCs using data coded according to a standard clinical terminology system, additional terms must be proposed and adopted. Corresponding information models, such as CDA templates, require development and specific value sets must be identified.

An Analysis of Medication Adherence of Sooner Health Access Network SoonerCare Choice Patients

Nicholas A. Davis, PhD[1], David C. Kendrick, MD, MPH[1]

[1]University of Oklahoma School of Community Medicine, Tulsa, OK

Abstract

Medication adherence is a desirable but rarely available metric in patient care, providing key insights into patient behavior that has a direct effect on a patient's health. In this research, we determine the medication adherence characteristics of over 46,000 patients enrolled in the Sooner Health Access Network (HAN), based on Medicaid claims data from the Oklahoma Health Care Authority. We introduce a new measure called Specific Medication PDC (smPDC), based on the popular Proportion of Days Covered (PDC) method, using the last fill date for the end date of the measurement duration. The smPDC method is demonstrated by calculating medication adherence across the eligible patient population, for relevant subpopulations over a two-year period spanning 2012 - 2013. We leverage a clinical analytics platform to disseminate adherence measurements to providers. Aggregate results demonstrate that the smPDC method is relevant and indicates potential opportunities for health improvement for certain population segments.

Introduction

Medication adherence generally describes whether patients fill their medication prescriptions at the designated frequency (e.g. monthly). Other related concepts include *compliance* (taking the medication as directed) and *persistence*, which deals with the overall duration of a drug therapy. While these terms are sometimes used interchangeably in the literature, *adherence* is commonly applied when measuring patient use of one or more concurrent prescriptions.

The rate at which patients fill new prescriptions is called *primary adherence*. An acceptable level of medication adherence, considered high adherence, has been generally established at 80% or above[7]. However, some medications, such as antiretrovirals for HIV/AIDS, may require a higher threshold at 90% or greater[17]. Non-adherence occurs whenever patients fail to fill their prescriptions entirely, or delay the act of filling. In recent years, non-adherence is an area of active research and mounting concern for many parties in the healthcare industry, including clinicians, healthcare organizations, and payers[7]. As stated by former US Surgeon General C. Everett Koop, "Drugs don't work in patients who don't take them."

Several studies have been published that demonstrate an association between medication adherence and health outcomes. In cardiovascular disease patients, high adherence to antihypertensive medications has been associated with higher odds of blood pressure control compared with patients having medium or low adherence[10]. Non-adherence to cardiovascular drugs has been linked with increased risk of morbidity and mortality[11]. Low adherence to heart failure drugs has been associated with an increased number of cardiovascular-related emergency department visits[12]. Patients with chronic diseases such as hypertension and diabetes have an alarmingly high rate of non-adherence, 28.4% and 31.4%, respectively[13]. Medication non-adherence is prevalent among patients with diabetes mellitus[14] and psychiatric illness[15]. Among patients with psychoses, the mean rate of adherence is 58%, and among those with depression the mean rate is 65%[15].

With a growing percentage of the population taking prescription drugs, medication adherence has been called "the next frontier in quality improvement"[8]. According to a recent Mayo Clinic study of drug prescriptions in a representative sample of the US population (n=96,953), over 68% of the study participants were taking at least one prescription drug[9]. Additionally, the study found that the percentage taking prescription drugs is rising, from 44% in 1999-2000 to 48% in 2007-2008[9]. Thus, adherence is an issue affecting the majority of US citizens.

In addition to the adverse effect on health outcomes, non-adherence also has a severe economic impact. Several studies have shown the increased costs to the healthcare system for patients with low adherence rates[14,16]. A recent estimate of the impact of non-adherence is $170 billion annually in the US alone[13]. Thus, medication non-adherence is a major impact to our national health outcomes and economy, and clinical interventions to improve adherence are critical.

In this study, we seek to characterize medication adherence behaviors of Oklahoma Medicaid patients whose providers also participate in the Sooner Health Access Network (HAN) by using pharmacy insurance claims data from the Oklahoma Health Care Authority (OHCA), with an aim to understand opportunities across demographic and drug categories. In addition to utilizing existing clinical analytics tools, we have developed an alternative method and corresponding software for calculating adherence. We present the results from initial analyses on the OHCA Medicaid pharmacy records and identify room for improvement across a number of patient demographics. Leveraging this data on local medication adherence rates may enable clinicians to have a positive impact on patient health outcomes.

Background

After a review of the literature on medication adherence, *proportion of days covered* (PDC) arose as the preferred method used to calculate adherence. A closely related and often-used method is *medication possession ratio*, or MPR. One particular improvement with PDC over MPR is its more conservative estimate of adherence. For example, a patient who fills a prescription early during the measurement interval may result in an "extra fill" in the calculation, leading to an overestimated medication adherence. MPR has been criticized for its tendency to overestimate the true rate of adherence. Additionally, PDC correctly accounts for cases where patients switch medications during a calculation interval, and there is overlap between the prior and new medication. PDC has been endorsed by the Pharmacy Quality Alliance (PQA), Centers for Medicare and Medicaid (CMS), National Committee for Quality Assurance (NCQA) and National Quality Forum (NQF)[17,18] as the preferred method for calculating medication adherence.

Whereas MPR sums the days supplied for a medication over the measurement interval, PDC employs the concept of time arrays to reflect the dates encompassed by each prescription fill. For example, a thirty-day supply on June 1st would generate a time array that would cover June 1 - 30. After all time arrays have been created for a particular medication or class, these can then be aggregated and used to determine the number of days that were covered by at least one array. This comprises the numerator of the measure. The denominator of PDC is the number of days between the first prescription fill of the medication and the end of the measurement period. This number is typically expressed as a percentage, so is multiplied by 100 prior to display. Below is the equation used to calculate adherence according to the PDC method:

$$\text{PDC} = \frac{\text{Number of days covered by at least one drug in the class}}{\text{Number of days in measurement period}} \times 100$$

Additionally, when medication adherence is calculated across an entire population, or a segment of a population, the rate may be expressed as a performance measure. In this approach, each individual patient's adherence is formulated using the method described above. The population's or segment's adherence rate is then calculated by counting the number of patients with a PDC greater than or equal to 80%, and then dividing by the total number of eligible patients.

The School of Community Medicine at the University of Oklahoma (OUSCM) Tulsa was established to address the tremendous disparities in health outcomes and healthcare access in Oklahoma. OUSCM has closely tracked the shift in payment models from strictly "fee for service" to the more risked-based shared savings models. OUSCM has committed to supporting a shift in delivery models from individual physicians practicing largely autonomously to patient-centered medical home teams[3], which employ a team of care providers (including clinicians, nurses, social workers, pharmacists and other staff) to maximize the efficacy and efficiency of a patient's treatment. A key strategy in the school's mission is the application of health information technology (HIT) to addressing these issues. HIT can help clinicians to provide timely, equitable, and affordable treatment options.

Crucial in the deployment of HIT is the adoption of electronic health records (EHRs). While EHRs provide compelling advantages on an individual patient basis, they are often not designed to enable an aggregate view of

population health and care team management outcomes. Thus, an often-required parallel component in the deployment of HIT systems is the creation of a data warehouse and analytics tools for storage and analysis of patient EHR data.

Complementary to the OUSCM clinical data available from the EHR is the availability of insurance claims data from the Oklahoma Health Care Authority (OHCA)[1], Oklahoma's Medicaid Agency. In 2009, OHCA converted their largest covered population, SoonerCare Choice members, into a Patient Centered Medical Home delivery model and in 2010 added the Health Access Network program to provide support for the Medicaid providers and their patients transitioning to the PCMH model. The largest of three health access networks, the Sooner Health Access Network (HAN)[2], is operated by a team from OUSCM and offers care management services, PCMH tier advancement support, quality improvement, and health data analytics support to Medicaid providers throughout Oklahoma. The HAN receives claims data feeds for the Medicaid patients attributed to the Medicaid providers enrolled in the HAN. OHCA sends claims data of three types in three different formats: UCE 1500 for professional fees; UB 92 for facility fees (i.e. hospitals and hospital-based ambulatory and lab fees), and character-delimited plaintext files based on the NCPDP format for pharmacy claims. The HAN analytics team processes the claims data onsite. Pharmacy claims data are stored in a SQL Server 2008 database built for this purpose. Updated records for the pharmacy data set are sent monthly from OHCA, and this comprises the data used for this research in medication adherence.

OUSCM utilizes Pentaho, an open source Java-based business intelligence (BI) platform, for its clinical analytics system. Pentaho provides analytics, reporting, and health performance dashboards. Pentaho is a component of an enterprise data warehouse that stores historical data on care management, quality indicators, research studies, and clinical and insurance data sources. The clinical and claims data feeds arrive in their native formats and must be processed in a sequence of steps. Via Pentaho Data Integration (PDI), HAN's business intelligence developers construct intricate data extract, transform, and load (ETL) pipelines using a GUI-based visual design tool. As described in Methods, this environment was augmented to create an ETL workflow and analytics dashboard for medication adherence data.

The following materials and software were used for this research:

- Sooner HAN SoonerCare Choice pharmacy claims data on 133,757 patients, for a total of 3,926,135 individual records. This was filtered to 2012-2013 data and using the algorithm described in Methods.
- RxNorm database version August 5, 2013 Full Update release version
- NPPES National Provider Identifier (NPI) database, July 2013
- R 3.0.2 and RStudio 0.98
- Pentaho 4.5 GA Release, including Analysis Server, Pentaho Data Integration, Schema Workbench
- SQL Server 2008 R2 and Oracle SQL Developer 4.0

Methods

While PDC has been defined concisely as described above, there remains a degree of freedom when employing the algorithm. Specifically, the duration of the measurement period used in the denominator is left to the researcher to determine. Some studies use a period of one year or six months, but this is usually chosen to be appropriate to the particular population segment in question. One challenge with conventional PDC durations is the selection of the measurement period to accurately calculate adherence for a variety of medications and patients. In the literature, studies often calculate medication adherence separately for patients in different segments, such as disease categories. For our purposes, it is desirable to calculate adherence across several segments at once, so that the behavior of the adherence calculation can be studied and its correlation to clinical outcomes evaluated.

Therefore, we set out to calculate adherence *en masse* using a robust approach. We employ the last prescription fill date (the day the patient filled their prescription at a pharmacy) for each medication corresponding to an individual patient. Our approach is a slight modification of the standard PDC method described above that we term Specific Medication PDC, smPDC. While it is true that the patient possesses a full cycle of medication at the last fill date, we have no mechanism, such as a subsequent fill event, to accurately determine whether the patient has indeed taken the medication. A reasonable proxy is the end of a measurement period (i.e. the last prescription filled by a patient occurs prior to the end of measurement), but the assumption required is that the patient has taken the medication.

Thus, to be conservative and avoid an overestimated adherence, we select the last fill date as the end of the measurement period. By utilizing the last fill date, we avoid an unnecessary gap near the end of a static measurement duration (e.g. end of calendar year) that can occur if a patient discontinues a medication. This gap may result in an adherence calculation that underestimates the true value of medication adherence. In addition, the termination of a prescription may be the result of a change in the patient's enrollment status or their PCP leaving the HAN program, but this information is missing from our OHCA pharmacy data set.

A patient may fill a prescription early by a few days. When this occurs, the patient possesses a quantity greater than a single day's supply on the days prior to the end of the original prescription. This would extend the true count of the days covered by a medication by the number of early fill days. The standard PDC algorithm neglects these early fills days in calculating adherence, but there is a modified version that accounts for early fills. Using Specific Medication PDC, medication adherence is calculated as follows:

$$\text{smPDC} = \frac{\text{Number of days covered by at least one drug in the class}}{\text{Number of days between last and first fill}} \times 100$$

An example will serve to illustrate the method. Our patient, Mitch, has a prescription of a renin-angiotensin inhibitor for a cardiovascular condition. Each prescription is a 30 day supply (one pill per day), with refills provided on a monthly basis. Mitch fills the first prescription on March 15, a second on April 18, a third on May 18, and the final on June 23 as shown in Figure 1. To calculate Mitch's adherence to the renin-angiotensin inhibitor, we first determine the duration (representing the denominator in the equation above). Duration is calculated using the number of days between the first and last fill date, in this example between March 15 and June 23, which is 100 days. The numerator is determined based on the number of days covered by the prescription, which is 30 * 3 = 90. Thus, Mitch's adherence to the medication over the duration is 90/100 * 100 = 90%. This can also be calculated in an alternative manner by taking perfect adherence, 100 days, and subtracting the gaps (representing non-adherence) in the prescription fills as illustrated in Figure 1. 100 - 4 - 6 = 90, which coincides with the 90% adherence previously calculated.

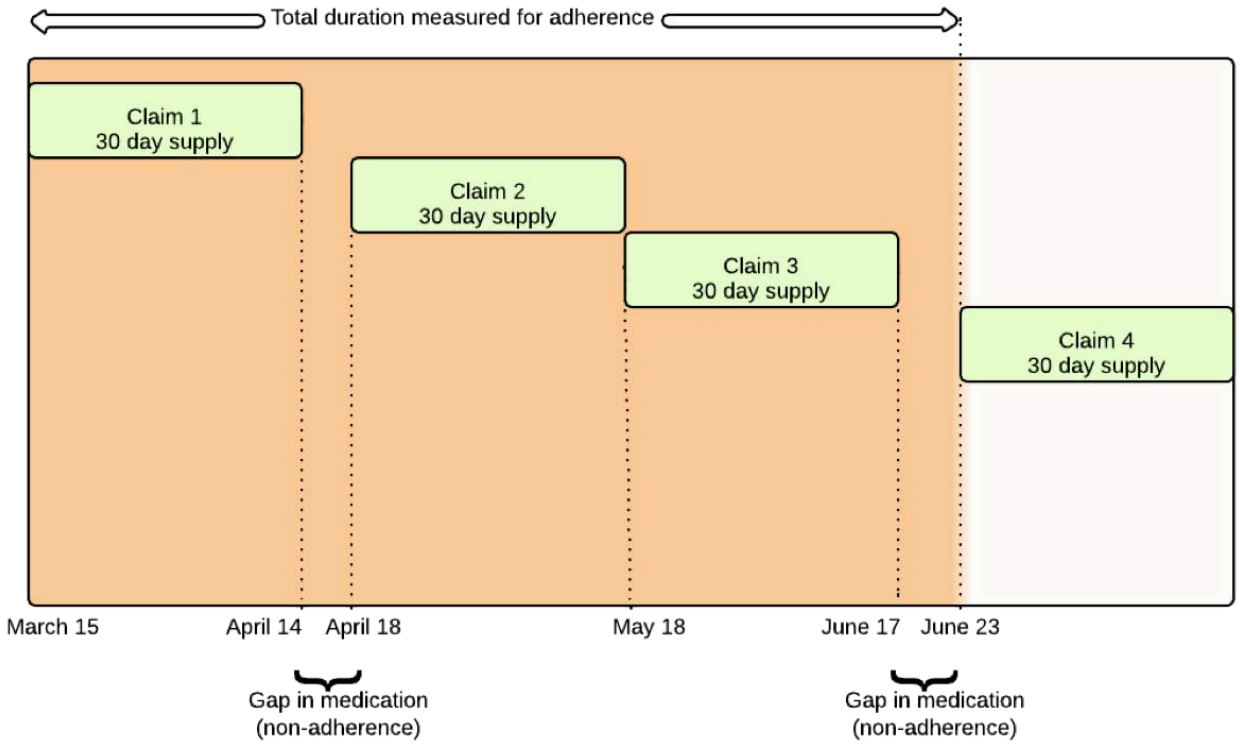

Figure 1. Example medication adherence calculation diagram

A series of filters is applied to the original OHCA pharmacy claims data set. Patients with two or more fills for a particular medication are selected from the entire set of records. A least two prescription fills are required for each patient/medication combination in order to determine the duration between successive prescriptions using the smPDC method. Patients with a single prescription fill of a particular medication are thus excluded from the analysis. Next, records that occur in the 2012 - 2013 timeframe are preserved and the remainder filtered. This two-year study period focuses the analysis on the most current full subset of prescriptions. To be included, the initial prescription fill must occur on or after 1/1/2012 and the last prescription fill on or before 12/31/2013.

Additionally, the claims records received from OHCA included denied claims and reversals. Reversals occur when an original paid claim is later modified or reversed to a denied status. If a claim is denied, it is unlikely that the patient has been issued the medication from the pharmacy (otherwise the pharmacy would be ineligible for reimbursement from Medicaid). Reversals are essentially updates to an existing record, and usually involve correcting clerical errors on a previous claim. For instance, the pharmacist may inadvertently specify the wrong quantity of pills. Reversals are discrete records, thus the final paid claim is used when one or more reversed claims exist for a particular prescription. We exclude both denied claims and reversals from the analysis.

To complement the Medicaid pharmacy claims data set, a couple of external data sources were integrated into the OUSCM enterprise data warehouse. RxNorm[19] from UMLS is used to relate a specific drug code (NDC or National Drug Code[6]) descriptor to an RxNorm concept identifier. RxNorm is further used to identify a VA drug class for each medication, using an approach similar to the algorithm described in Parthak et al[5]. Although each pharmacy record has an existing class provided by OHCA, the VA drug class is more granular in its categories, and is also familiar to clinicians at OUSCM. Provider details are also incorporated from the CMS NPPES National Provider Identifier (NPI) database. The prescribing provider NPI is a data element in the OHCA pharmacy records, and this is used to capture additional details including the first and last name of the provider. Both RxNorm and NPI data sources have been loaded from the provided source files in a SQL Server database and integrated in the analysis.

R is used to perform the initial adherence calculations using the smPDC method. R is an open source statistical framework and language with a multitude of add-on packages and libraries providing external functionality, with the added benefit of being used by a large community of researchers and scientists. R lends itself to trivial parallelism in many cases as well. The pseudocode of the medication adherence calculation is as follows:

1. Select data from SQL database using RODBC package. Denied claims and reversals are excluded, as are patient/medication combinations with fewer than 2 prescriptions. Data elements include patient ID, sex, age, drug code, drug name, drug quantity, days supplied, drug class, provider NPI. Additional data sources are joined and returned in the SQL query, including RxNorm, NPI, and OHCA drug class.
2. Trim the beginning and end of string columns from the raw data (inconsistent extra spaces confound the matching algorithm)
3. Partition the filtered data for parallel processing by patient ID and drug code (data is "embarrassingly parallel")
4. Run parallel algorithm (parallelized for a multicore machine) using mclapply. For each partition of the data:
    a. Calculate medication adherence
        i. Use smPDC as described above
        ii. Exclude durations <= 7 days (filter spurious records with fills within a week of each other for the same patient/medication)
        iii. Exclude first fills before 1/1/2012 and last fills after 12/31/2013
        iv. Set any medication adherence value to 1.0 (100%) if calculated value > 1
    b. Use early fills to extend the number of days covered

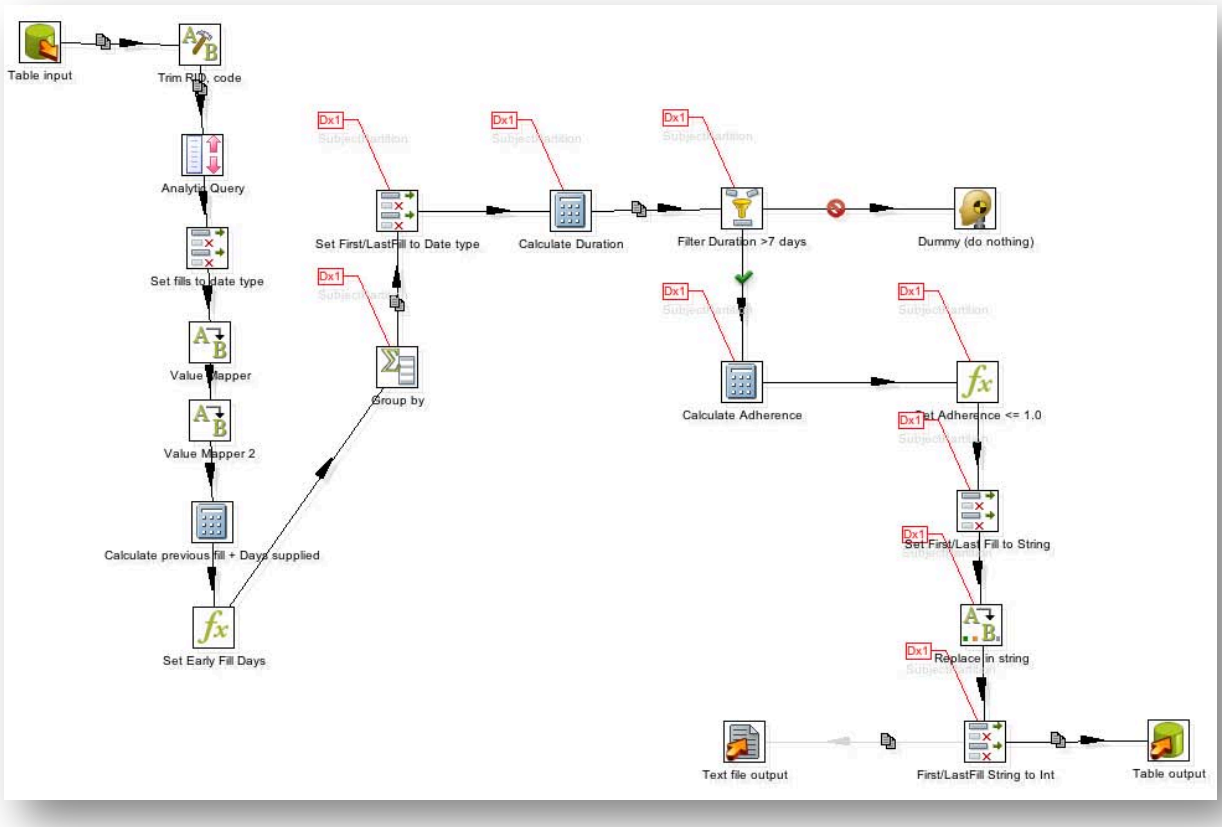

Figure 2. Pentaho Data Integration (PDI) transformation

As OUSCM clinicians, administrators, and staff use Pentaho for clinical reporting and analytics on patient treatment, quality of care, and other areas, we sought next to implement the code in this existing environment. The R code was ported to Pentaho Data Integration (PDI) for selection, filtering, and calculation of adherence results. A PDI transformation was created to perform this ETL step and write the results to a table in a SQL database. Figure 2 shows the resulting transformation used to calculate adherence, and matches the pseudocode previously described. This transformation is subsequently incorporated in a PDI job, which is then scheduled to run on a monthly basis to concur with the availability of the pharmacy claims data from OHCA. Note that this recurring workflow is no longer restricted to the two-year study period used for this research. Thus, historical adherence trends can be observed.

Schema Workbench, a GUI component of the Pentaho suite, is lastly used to create a Data Source that provides an interactive dashboard for medication adherence in Pentaho Analysis Server. The tool connects to the table storing the medication adherence results from the PDI calculations, as well as a number of existing data sources. Relevant data elements are included to allow exploration of the data by a number of attributes. Calculated measures are used to provide a mechanism to determine the mean adherence across a segment of patients or other categories.

Results

OHCA pharmacy claims data records exist from 1994 to the present, received on a monthly basis by the Sooner HAN. While the time span of these records is significant, > 97% of the data is very recent, from 2009 onward. In the unfiltered, original data there are over 3.9 million individual records for approximately 134,000 unique patients. After filtering the denied and reversed claims, as well as patient/medication combinations with fewer than two prescriptions, 2,206,026 records remain. A further filter for the two-year period from 2012 - 2013 produces 961,883 records covering 55,795 patients. This subset of data provides the basis used to calculate medication adherence for all 56K patients using the smPDC method.

Each medication is linked to a corresponding RxNorm concept identifier (RXCUI) using the RxNorm tables. The UMLS RxNorm source files provide the schema and data for a series of nine tables. RXNSAT (Simple Concept and Atom Attributes) is used to match a National Drug Code (NDC) from the OHCA pharmacy claims data to a corresponding RxNorm Concept Unique Identifier (RXCUI). A matching concept is identified for 97.8% (940,882) of the records in the filtered data.

Based on the identified RXCUI, we then match a drug with its VA drug class name. Each pharmacy record arrives encoded with a drug class code, assigned by OHCA, represented as an integer from 0 - 99, for a total of 100 categories. These codes are mapped to a table with class names, provided from OHCA as a data dictionary. The OHCA drug classes are assigned from First Data Bank (FDB)[4]. There are 411 distinct VA drug class categories in the RXNSAT table, providing a finer classification granularity for medications. For the matching algorithm, three tables are used: RXNSAT, RXNCONSO (Concept Names and Sources), and RXNREL (Related Concepts). Of the filtered data set, 97.2% (935,426) of the records map to a corresponding VA drug class.

Provider details are incorporated to allow mapping to prescribing physicians. Each pharmacy record contains the prescribing provider NPI, which is leveraged to identify the physician's first and last name. Nearly all records (>99.9%, 961,344) have a value for NPI. In the source table for this data, NPI, several rows are missing values for provider first and last name. Despite that, 99.7% (959,035) of records from the filtered data set have matching provider names when joined from the NPI table based on the prescribing provider NPI.

From the input filtered data set (~962K records/56K patients), the algorithm further filters out prescriptions of the same patient/medication with a duration less than or equal to seven days. With this filter applied in the medication adherence calculation, the patient count is 46,568. The adherence calculations are written to an Adherence table that includes patient ID, drug code, first and last prescription fill dates, duration, OHCA and VA drug class names (two distinct columns), provider NPI and first and last names, and of course the calculated adherence score. Adherence has a total of 138,686 rows, with each row representing a unique patient/medication combination.

Table 1. Medication adherence calculated with smPDC by segment, 2012 - 2013

Segment	Sample size (n)	Mean adherence
All	46,568	56.08%
Sex		
Female	28,364	56.33%
Male	18,197	55.64%
Unknown	7	56.47%
Age		
< 18 years old	27,602	48.23%
18 - 25	5,573	54.29%
26 - 35	5,791	60.33%
36 - 45	3,265	65.24%
46 - 64	4,302	68.36%
65+	36	73.56%
Race		
American Indian/Alaskan Native	3,428	57.06%
Asian	526	50.84%
African American	9,766	53.04%
Native Hawaiian/Pacific Islander	96	52.11%
White	29,731	57.40%
Drug class		
Psychostimulants-Antidepressants	7,439 (12,728)	61.61%
Narcotic analgesics	8,246 (13,396)	54.19%
Glucocorticoids	5,833 (7,305)	51.21%
Antihypertensives	3,253 (4,409)	61.79%
Anticonvulsants	3,733 (5,883)	63.59%

Table 1 shows the results of the calculations. The mean adherence for each segment is presented in the far right column, with the sample size in the second column and the segment in the first. Adherence results are calculated on segments by sex, race, age, and a few of the top drug classes as ranked by quantity of prescriptions. Overall, mean adherence is ~56% for the filtered data set. In the second column, under drug class segments, the number in parentheses indicates the total number of patient/drug combinations for each drug class. Each patient/drug combination will have at least two prescriptions, as this is required to calculate medication adherence using smPDC.

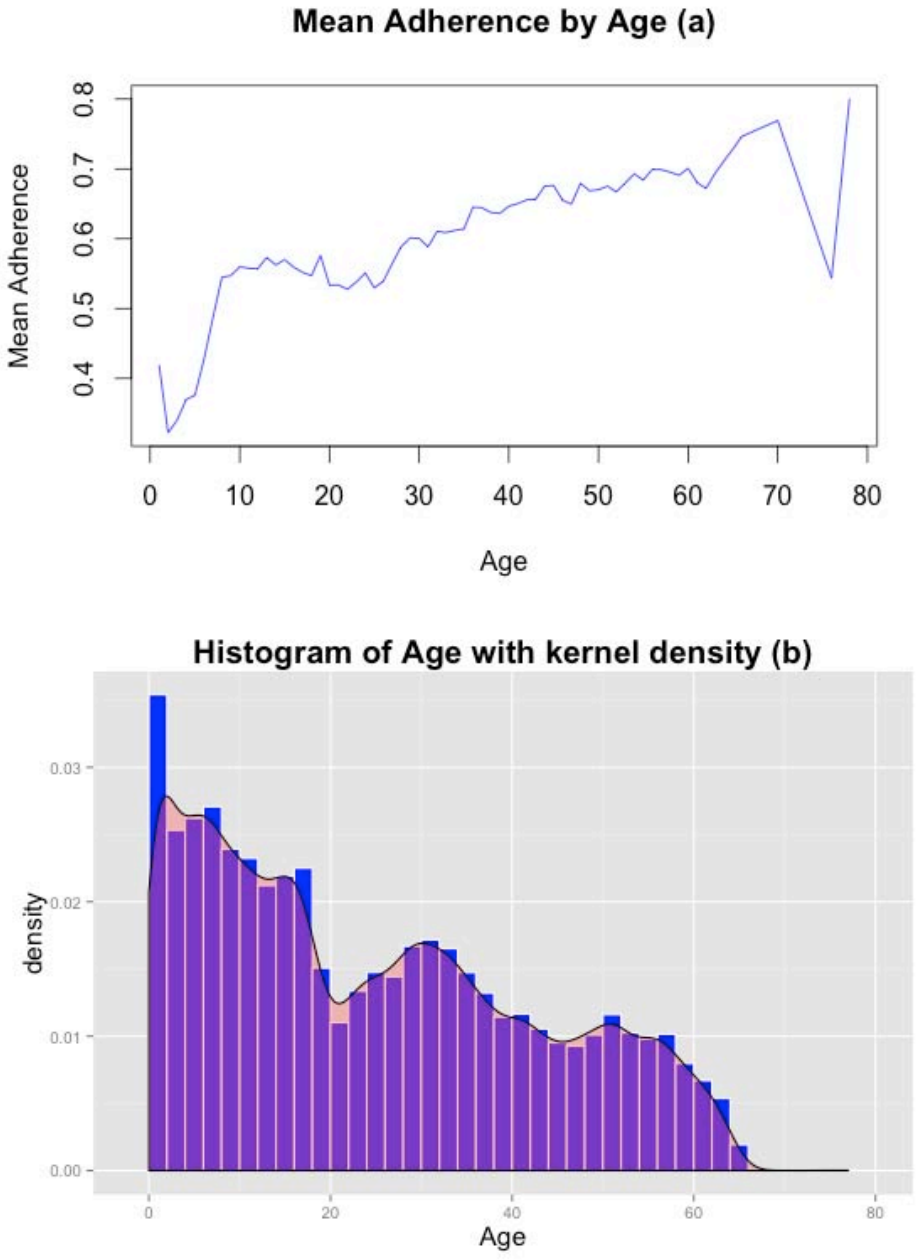

Figure 3. Mean adherence by age (a) and histogram and kernel density curve of age (b)

To capture the trend of adherence rates for various ages, the mean adherences are calculated for each discrete age in the filtered data set. Figure 3a displays a graph of mean adherence by age. Mean adherence generally increases with age, with a slight dip in the early- to mid-twenties. A local minimum is reached at age 75, with a sharp

increase to the global maximum of 80% adherence at age 77. Figure 3b shows a histogram of the population by age, using bins of 2 years. The largest segment of the population by age is clearly 0-2 years, with a local maximum at 6-8 years. After age 18, a sharp decline is seen in the number of patients, followed by additional local maxima at 30-32 years and 50-52 years.

Discussion

With an overall mean medication adherence of ~56%, the results illustrate that adherence rates can be calculated using these methods, and that there may be opportunity for improvement in adherence rates across all populations. Across genders, the adherence rates were essentially the same for males and females (~.7% greater adherence for females). As seen in both Table 1 and Figure 3, medication adherence increases with age across the population. The youngest age groups 0-2, 2-4, exhibit the lowest adherence rates out of any of the segments measured in this study (42% or lower). Among the drug classes, patients with high blood pressure and epileptic seizures display the highest adherence (61.79% and 63.59% for Antihypertensives and Anticonvulsants, respectively). The lowest adherence among the most frequently prescribed drug classes is seen in the Glucocorticoids (51.21%), used in inflammatory disorders such as asthma, and not generally intended for long term use.

There are a few ways to account for patient age in this study. Date of birth is the actual value present in the original data, thus the age is a calculated value. Originally age was calculated based on the age of the patient on the prescription fill date. This presented a dilemma, as patients with multiple prescriptions over the two-year study period would naturally have a birthday (and perhaps two) during the measurement period. Patients with multiple ages confound the calculation of mean adherence across age-based segments. Thus, a decision was made to set the value of the age of a patient to individual's age on 1/1/2013, or the midpoint of the study period.

Another challenge present in the data occurred with the labeling of sex for individuals. While greater than 99.99% of the patients had a consistent value set for each prescription record, a small number (7) of patients had sex codes for both male and female. It is unclear if this represents legitimate cases or is a clerical error. Nonetheless, these individuals were placed into the Unknown category shown in Table 1.

In this study, all drug classes were taken into consideration for the analysis. Future research will further characterize medication adherence for chronic illnesses, such as diabetes and cardiovascular disease. Additionally, some medications are prescribed as PRN, or take as needed. There are no indicators within our data set of whether a medication is prescribed as PRN. However, medications from certain drug classes are often prescribed as PRN, which could be used as a proxy for PRN medications. It is also possible that the rate of chronic drugs vs. PRN medications increases with age as well (not explored in the current analysis). While some of the code and queries used in this research are specific to the HAN Medicaid data set, the tools are generalizable and may be used to calculate medication adherence in any similarly structured pharmacy claims data set.

While the present results are focused on the two-year measurement period, medication adherence is calculated for all years and accessible to authorized OUSCM clinical staff and researchers via the Pentaho web-based portal. In the Medication Adherence environment, users can explore adherence by individual patient, provider (e.g. a clinician can view his or her patient's adherence results), drug class, and a number of additional dimensions. Aggregate information is also available for researchers interested in population health statistics.

Conclusion

We have presented the results of the medication adherence rates for a subset of Oklahoma Medicaid patients enrolled in the Sooner Health Access Network. Prior to this work, our community medication adherence rates remained elusive. Armed with this information, health care managers can now begin the task of working with clinicians to improve these rates across a broad range of population segments, beginning with the most critically non-adherent patients. Future initiatives of our research include selecting specific chronic conditions or disease categories for study and working closely with clinicians and clinical teams to generate periodic reports for patient teams. Ultimately, the goal is for medication adherence rates to appear in each patient profile, which will require integration of adherence calculations in the existing EMR user interface. This will allow providers to determine which patients exhibit low medication adherence during patient encounters and thus have a positive impact on patient health outcomes.

Abstract

An opportunity exists for meaningful concept extraction and indexing from large corpora of clinical notes in the Veterans Affairs (VA) electronic medical record. Currently available tools such as MetaMap, cTAKES and HITex do not scale up to address this big data need. Sophia, a rapid UMLS concept extraction annotator was developed to fulfill a mandate and address extraction where high throughput is needed while preserving performance. We report on the development, testing and benchmarking of Sophia against MetaMap and cTAKEs. Sophia demonstrated improved performance on recall as compared to cTAKES and MetaMap (0.71 vs 0.66 and 0.38). The overall f-score was similar to cTAKES and an improvement over MetaMap (0.53 vs 0.57 and 0.43). With regard to speed of processing records, we noted Sophia to be several fold faster than cTAKES and the scaled-out MetaMap service. Sophia offers a viable alternative for high-throughput information extraction tasks.

Introduction

There is a pressing need for clinical concept extraction and concept indexing to unlock currently obscured information from large corpora holding clinical narratives. Natural language processing (NLP) tools such as MetaMap[1], cTAKES[2] and HITex[3] have traditionally been used for concept extraction and have performed well in the clinical domain. However, these have not been scaled-up to handle big data while preserving processing speeds. Large health care systems such as Kaiser Permanente, Mayo, Vanderbilt and the US Department of Veterans Affairs (VA) would have need for scaling up their concept (information) extraction tasks. As an example, the VA maintains a fast growing corpora of 2.6 billion clinical notes through a secure research environment (Veterans Informatics and Computing Infrastructure, VINCI[4]). Using currently available tools running on several multi-core servers, we estimated that it would take multiple years to create concept indexes for the notes available in VINCI notes to facilitate further information extraction and retrieval.

For clinical, health services and genomic research, there is a critical and ongoing need for NLP tools to mine the free text of medical records to supplement structured data queries to identify patient cohorts and phenotypes. In developing these tools, researchers consider several criteria: usability, maintenance, efficacy (in terms of recall/precision/f-score), ability to incorporate and use local lexica (or terminology), high throughput performance and adoption within the NLP community. While no currently available tools satisfy all criteria, we set out to develop a tool which would be useful for high throughput while maintaining efficacy.

We report the development of Sophia which is a UIMA-AS[5] based UMLS[6] concept extraction annotator. Sophia is now a key component of the v3NLP Framework used by VINCI for information extraction tasks. Sophia shares some methodologies found in MetaMap and cTAKES, but includes some attributes that cTAKES does not, and also excludes some functionality that MetaMap has. More importantly, Sophia is designed for fast processing, while most prior efforts emphasize extraction accuracy.

State of the Art in Extracting UMLS Concepts

There are a number of open source NLP tools and techniques specifically developed to extract UMLS concepts from clinical text. Among them, cTAKES and HITex are well represented in the field. MetaMap and SAPHIRE[7] were tools initially designed for UMLS concept extraction within the bio-literature domain that have been adapted for use with clinical text by several organizations. There are a number of non-open source successful efforts to extract UMLS concepts within clinical text include MedLEE[8], MedKAT[9] and KnowledgeMap[10].

Many of these efforts are built upon two frameworks adopted or developed for use within the NLP field: GATE[11] and Apache-UIMA. A relevant component common to these two frameworks is the notion of a pipeline

composed of a sequence, or end-to-end chaining, of atomic modules often referred to as annotators. An annotator adds stand-off highlights, mark-ups, labels or annotations related to the original text. The annotations from one module are used as input to a downstream annotator. A phrase chunker annotator, for example, depends upon part-of-speech annotations added via an upstream annotator in a pipeline. Efforts built upon the UIMA platform have the potential for being scaled out through the replication of pipeline instances via a related framework: Apache UIMA's Asynchronous Scale-out[12] (UIMA-AS). The UIMA-AS framework provides for pipeline component replication in addition to the full pipeline instance replication to address bottleneck annotators.

Methods

Sophia Annotator Defined

The Sophia annotator identifies UMLS Concepts using a lookup algorithm to match longest spanning matches to an index of known UMLS concepts. A conscious decision was made to find longest spanning matches rather than shortest spanning or by including all possible matches. Longest spanning matches reduce the ambiguity issue by finding the most specific match, for instance finding *chest pain* rather than *chest* and *pain*. While including the constituent components such as pain and chest might be useful for building google-like search indexes to aid retrieval techniques, the first iteration of Sophia does not include this capability because such a capability was not part of the motivating use cases.

The lookup algorithm relies on exact match retrieval to keys in the index, rather than uninflected or stemmed key retrieval. An exact match retrieval looks up the words as they appear in the sentence to find keys in an index. Within the sentence the *patients were transferred*, exact match retrieval would look up the words patients, were, and transferred within a dictionary. Within an uninflected lookup algorithm, each of the words within the sentence would be transformed into the uninflected keys: patient is transfer. These uninflected keys are what would be looked up within an index that holds the uninflected forms. The index includes all possible fruitful variants[13] for a given UMLS concept to insure that valid matches will be found. Fruitful variants for a given term includes spelling variants, inflections, synonyms, acronyms and abbreviations, acronym and abbreviation expansions, derivations and combinations of these transformations such as the spelling variants of synonyms. The burden of computation to make a match is shifted from the cost of normalizing words in the text to be looked up, to having a larger index where the variant expansion cost was taken up at index creation time. An early MetaMap paper[14] showed that this technique increases match precision or accuracy over stemming normalization techniques.

The lookup algorithm works on a window that initially includes all the tokens of a sentence as the longest span to find. Subsequent lookups drop successive tokens from the beginning of the sentence until a match is made. The algorithm does not rely on phrasal boundaries on the grounds that there are important UMLS terms that include multiple phrases, particularly those that include multiple prepositional phrases (*of*, *with*, *without*, *with/without*). Techniques that rely on phrasal barriers to determine the window size sometimes miss the longer, less ambiguous, more specific matches. Both MetaMap and cTAKES have post phrase identification to re-join specific kinds of prepositional phrases to the adjoining noun phrases to partially ameliorate this condition.

No phrasal boundaries are necessary for Sophia's lookup technique. As a consequence, no part-of-speech tagger is necessary to identify phrasal markers, eliminating two common up-stream annotators commonly found in other concept extraction systems.

The Sophia lookup algorithm evolved from the SPECIALIST Text Tools[15]. The SPECIALIST Text Tools lookup dropped tokens from the beginning side of the sentence where-as the Sophia algorithm drops tokens from the ending side of the sentence. While neither version is perfect, dropping tokens from the ending side of the sentence favors having the head of a term as the last token matched. For example, the prior version would have matched *heavy chain* and *smoking* from the sequence *heavy chain smoking* whereas the current version would match *heavy* and *chain smoking*, given the situation where the index includes *heavy chain*, *chain smoking*, and *heavy* as keys (and not *heavy chain smoking*).

The index entry key creation is important to the overall Sophia scheme. Each UMLS string has a set of lexical variants generated to create keys in the Sophia index. These lexical variants include spelling variants, inflections, un-inflections, synonymy, derivations, acronym or abbreviation expansions and acronyms and abbreviations. Fruitful combinations of each of the above mentioned variants are also generated including derivations of spelling variants, derivations of synonyms, and derivations of derivations. These variants are generated from a configuration of the LVG tool[16] distributed by the National Library of Medicine called the

fruitful variants flow. This tool over-generates variants for Sophia's purposes. Variants that are generated from terms that, themselves are acronym/abbreviation are most likely fallacious. For instance, generating spelling variants to the acronym *A.I.D.S.* generates the term *AIDS*, applying (un) inflections to that term creates *AID* (already fallacious), and applying either inflectional or derivational suffixes such as *ing* will lead to additional fallacious terms including *aiding*.

A post-processing filter is applied to prune out any variant generation combination that includes acronym/abbreviation or acronym/abbreviation expansion plus any additional mutation. Long sequences of synonyms or derivations are likewise pruned out.

The Sophia Pipeline

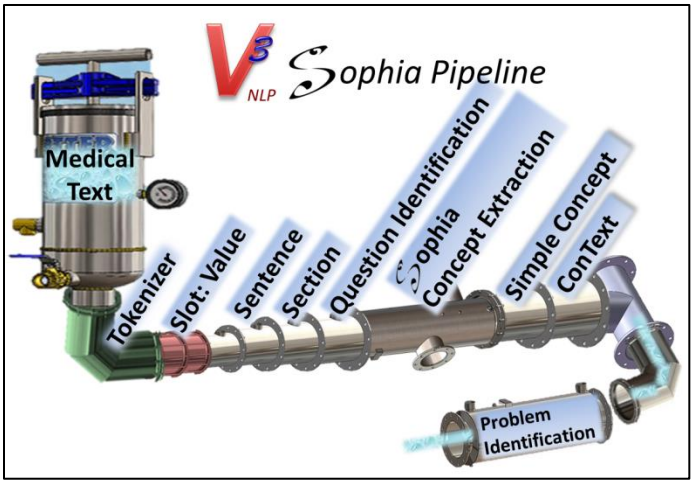

Figure 1. v3NLP Sophia pipeline

To evaluate Sophia against MetaMap and cTAKES, we created a pipeline that includes the prerequisite upstream annotators, the Sophia annotator, and needed downstream annotators (the Sophia Pipeline). The pipeline is built upon the UIMA-AS framework and is expected to be configured to utilize the resources of well-endowed production hardware to provide big-data concept extraction across the Veteran Administration's 2.6 billion clinical records.

The Sophia annotator works on the tokens within sentence or utterance boundaries. As such, the Sophia annotator requires upstream token and sentence annotators to identify words and sentences. Sophia was developed with the v3NLP framework, which includes token and sentence boundary annotators. V3NLP's sentence boundary annotator takes advantage of an annotator that identifies *slot:value* structures (they have a special kind of sentence grammar), and an annotator that identifies section headings. Since many clinical notes include question and checkbox boiler-plated sections, an annotator was added to recognize questions and their related checkbox structures to correctly handle concept assertions within these entities. The Sophia Annotator will blindly find UMLS concept mentions. The conText[17] assertion annotator is run downstream of the Sophia annotator to provide assertion attributes to the concepts found. Figure 1 shows a skeuomorphic representation of the Sophia pipeline with a medical problems identification annotator at the tail end of the pipeline. The problems identification component was added here to extract medical problems from clinical text as an extrinsic evaluation.

Evaluation

The Sophia Pipeline, MetaMap Pipeline and cTAKES were evaluated in an extrinsic task to identify medically significant problems mentioned in clinical text. The evaluation includes a span comparison compared to a human reference set and the throughput performance, i.e., how many records per second were processed. This paper provides the basis for baseline efficacy and performance metrics of the software devoid of the deployment environment.

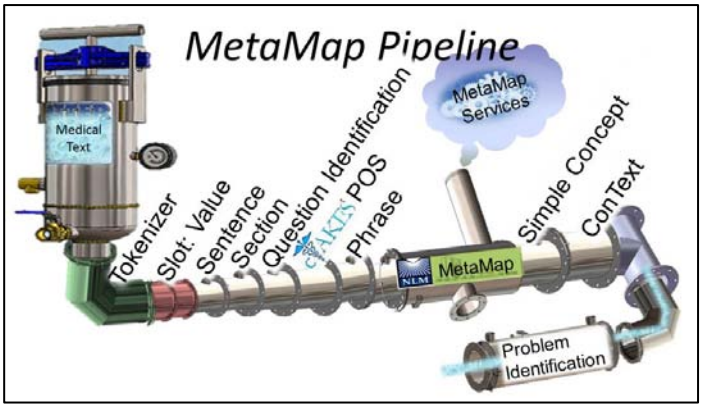

Figure 2. MetaMap pipeline

Span Evaluation

A gold standard reference corpus with span level clinically significant utterances was developed through a Consortium for Healthcare Informatics Research[18] (CHIR) Information Extraction and Modeling task from the Veterans Administration. Human annotators highlighted problems (as defined by the i2b2/VA 2010 Challenge[19]) in 145 clinical records in a corpus chosen at random from the 100 most frequent VA document types by the annotation team that annotated the i2b2/VA 2010 Challenge. Assertion attributes of negation, conditional, and subject were also annotated for these problems.

A MetaMap pipeline and a Sophia pipeline were created for this effort. Each of the pipelines included the problem identification annotator after the concept extraction annotation. The problem annotator filtered to concepts that were of the proscribed problem semantic type. The conText annotator was also applied to add assertion attributions. The conText annotator marked concepts with asserted, negated, conditional, applies-to the-patient, and historical attributions.

Figure 2 shows the MetaMap pipeline used for this evaluation. The cTAKES part-of-speech annotator and a phrase annotator were added and the Sophia annotator is replaced with the MetaMap annotator. The MetaMap annotator is a wrapper around a client that goes out to a MetaMap service running on external machines. This annotator gathers and uniques the phrases for a given record, then makes one request out to the MetaMap service. The MetaMap service runs MetaMap in the *term processing mode*. The MetaMap service is a restful service that includes 60 instances of MetaMap. The service treats each incoming term as a new request to the next available MetaMap process. Even with this environment, 86% of the processing time taken within the MetaMap pipeline is taken within this one annotator when analyzed via the UIMA CPE tool.

The cTAKES application was run separately on the 145 records. The output was fed into a post processing v3NLP pipeline that converted the cTAKES UMLS concept annotations to the CHIR model's *CodedEntries*. The same problem annotator was applied. cTAKES includes assertion attributions.

The span level comparison was done with overlapping matching spans compared to the reference standard on asserted problems associated with the patient.

Both the MetaMap server and Sophia indexed using the 2011AA Level0+9 configuration. cTAKES uses the 2011AA SNOMED concepts. The evaluation used an f-score computed as

$$F\ Score = \frac{2(precision * recall)}{(precision + recall)}$$

where

$$precision = \frac{true\ positives}{(true\ positives + false\ positives)}$$

$$recall = true\frac{positives}{(true\ positives + false\ negatives)}$$

Efficacy Results:

Table 1 shows MetaMap, cTAKES, and Sophia compared to the 145 record reference standard. The evaluation was a span-only evaluation, where credit was given for partial matches. cTAKES has the overall better F-Score at 0.568, followed closely by Sophia at 0.531. MetaMap had an overall f-score of 0.431. Sophia performed better at recall with a metric of 0.71 followed by cTAKES at 0.66. MetaMap had a recall metric of 0.38. cTAKES and MetaMap had a precision metric of 0.5 vs Sophia's .422. Sophia's precision was noticeably lower because of a plethora of false positives for this task. Those false positives from Sophia that were reviewed indicated that many could have been considered medical problems associated with the patient but the annotators chose not to mark them as such.

Table 1. Problem span comparison

	TP	FP	FN	Recall	Precision	F-Score
MetaMap	436	436	717	0.380	0.500	0.431
cTAKES	757	760	391	0.660	0.500	0.568
Sophia	823	1125	325	0.717	0.422	0.531

Differences between Sophia, MetaMap and cTAKES

There was a large overlap between the systems. It cannot be construed that those concepts unique to one system or another are fallacious. Of interest is how well each system identified multi-word spans. The more tokens involved in the match, the less ambiguity is left for downstream processors to deal with. Table 2 shows the Sophia pipeline compared to MetaMap and cTAKES, using MetaMap and cTAKES as reference standards.

Table 2. Problem span comparison using MetaMap and using cTAKES as the reference standard

	TP	FP	FN	Recall	Precision	F-Score
Sophia compared to MetaMap reference standard	1000	1238	169	0.855	0.45	0.587
Sophia compared to cTAKES reference standard	1496	1117	562	0.727	0.57	0.641

Many of the differences found included how each system chunked phrases, with no clear indication of whether either system did better or not. Table 3 shows instances where MetaMap picked up multi-word concepts but Sophia chunked them into separate concepts and instances of where Sophia picked up multi-word terms that include phrasal barrier markers.

Table 3. Multiword matching differences between MetaMap, Sophia and cTAKES

MetaMap	Sophia	cTAKES
right sided facial weakness	facial weakness	facial weakness
multiple old infarcts	infarcts	Infarcts
	hard of hearing	
	change in bowel habits	
	lives with family	
	unable to sit	
	Sensitive to touch	

The largest category of differences between Sophia and cTAKES was that CTAKES annotated terms found in section headings that Sophia did not. A concept mention within a section heading would not indicate that the mention is related to the patient. For instance, a section heading Pain Management would not automatically indicate the patient has or does not have pain; only that there is a section in the document that includes a section with pain in the name. The reference standard did not include annotations from within section headings. The Sophia pipeline includes a sectionizer that marks section headings to be ignored. Table 3 shows multi-word terms that Sophia suggested that were missed by cTAKES.

Time Performance

The Sophia pipeline, the MetaMap pipeline and the cTAKES assertion aggregate annotator were run against two corpora on a development virtual machine (VM) provided by the VA to securely process clinical records. The CHIR reference standard has a shorter average character length than other available corpora. The i2b2 2010/VA Corpus[i] provided an additional benchmark to a corpus with known attributes within the NLP community. The fastest of 3 runs are reported here (Table 4). The throughput numbers are meant to be interpreted as a means to rank the relative performance between the three systems. The performance time of these systems on well-

[i] Parts of the Sophia pipeline were used within an entry in the i2b2 2010 VA Challenge. The whole corpus was used for additional training to improve pipeline components after the challenge. This training invalidates any efficacy evaluation to this corpus.

endowed production servers are vastly different than the VM's provided for development purposes or current desktop machines. cTAKES and Sophia performance time on the i2b2 corpus on the a core i7 desktop was 4 times faster than the development virtual machine, and the MetaMap performance time was 2 times faster on the same corpus on the core-i7 using a less endowed MetaMap server.

Sophia has a significant initialization cost to load all the keys into an in-memory hash. This initialization is the same whether kicking off one instance or 100 due to the way the hash is shared across server threads. The impact of this initialization becomes less as more records are processed. Table 5 shows the initialization cost and the average per-record cost with and without taking into account the initialization cost. The initialization cost with MetaMap is hidden behind the running MetaMap service that was employed. CTAKES does have an initialization time of 36 seconds vs Sophia's 40 seconds observed on a desktop core i7 with solid state drives.

Table 4. Time performance in milliseconds to run Sophia, MetaMap and cTAKES on two corpora of records

	# of Records	Sophia	MetaMap	cTAKES
i2b2 2010 VA Corpus	349	1,395,271 (23.24 min)	4,804,951 (80.08 min)	24,524,827 (408 min)
Problem Reference Standard Corpus	145	343,384 (5.7 min)	478,824 (8 min)	3,060,000 (51 min)

Table 5. Time performance to run Sophia on two corpora of records, reported in milliseconds

	# of records	Initialization in milliseconds	Average milliseconds per Record	Average milliseconds per record w/out initialization	Total milliseconds
i2b2 2010 VA Corpus	349	187,013	70,271	69,735	24,524,827
Problem Reference Standard Corpus	145	185,664	2,351	1,079	343,384

This time evaluation is not perfect. The number of external CPU's and threads employed by the MetaMap services makes it difficult to replicate the same MetaMap pipeline performance if moved to an environment that does not employ the VA's MetaMap services. Even with these constraints, the single threaded Sophia annotator out-performs the MetaMap annotator by a factor of 7 and out-performs cTAKES by a factor of 18.

Pipeline Performance Analysis

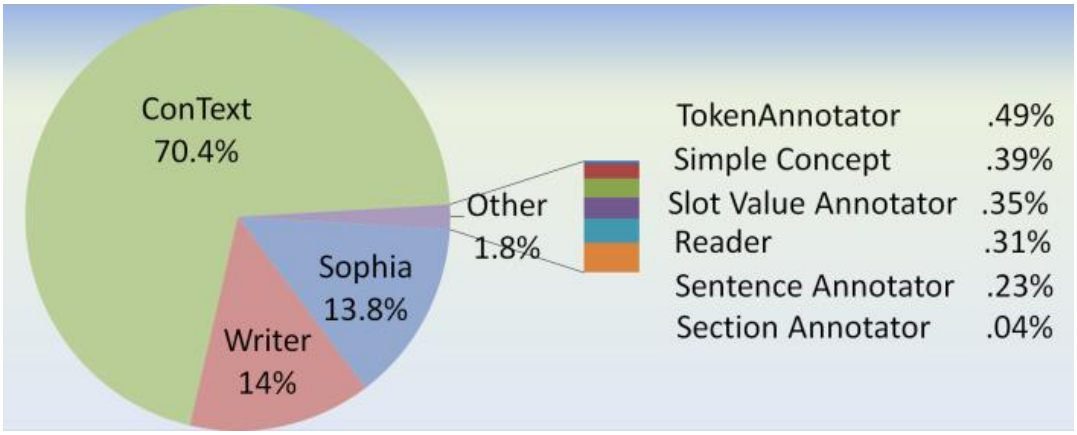

Figure 3. Sophia pipeline proportion of each annotator's processing

A pipeline performance analysis was performed to analyze the time contribution for each of the components within the Sophia, MetaMap, and cTAKES pipelines. The UIMA Component Processing Engine (CPE) was employed to break down each of the component times. See the pie charts in figures 3-5 of the relative amount of time each component consumed. It is the assertion component that takes up the most time (70%) within the Sophia pipeline, and the second highest amount of time (27%) in the cTAKES pipeline, yet it is a mere 9% within the MetaMap pipeline. Within Metamap and cTAKES, other components consume much more processing relative to the assertion module. Efficiencies to conText should be explored before improving performance elsewhere for the Sophia pipeline.

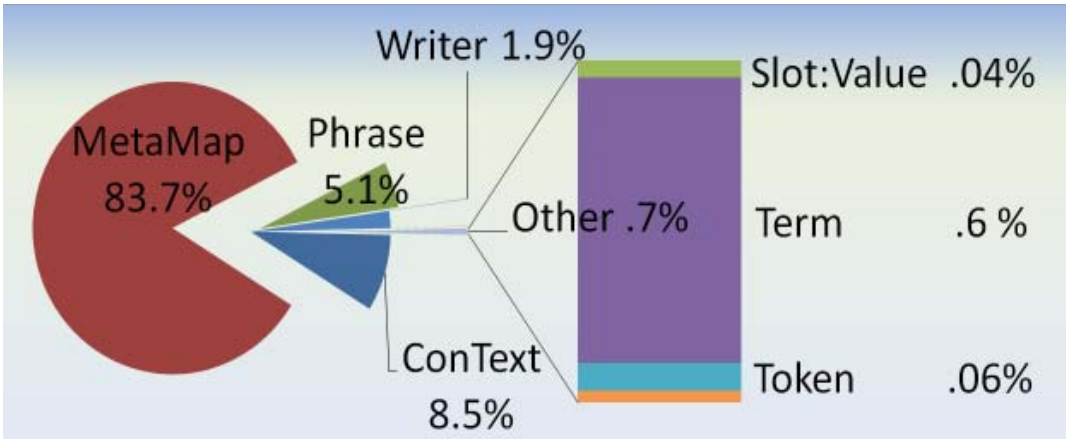

Figure 4. MetaMap pipeline proportion of each annotator's processing

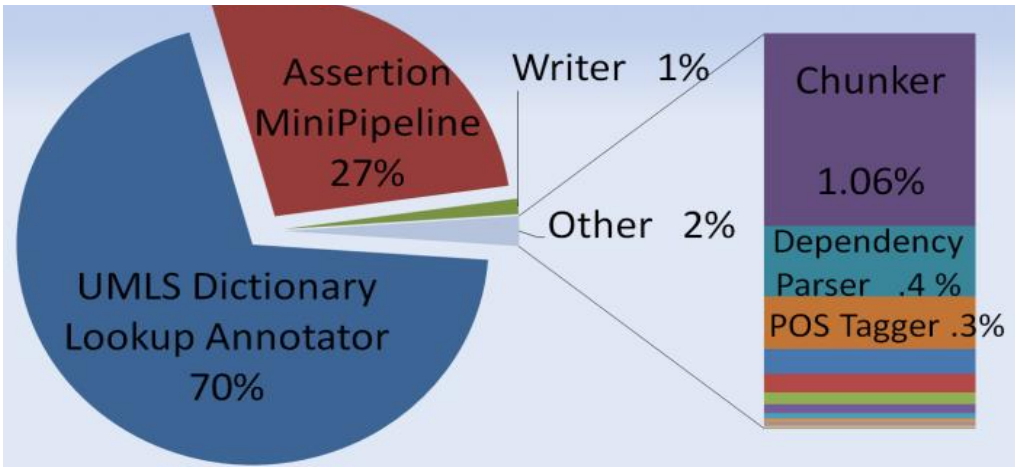

Figure 5. cTAKES pipeline proportion of each annotator's processing

Some efficiency had been built into Sophia's conTEXT wrapper, by spawning off a pool of threads to handle the conTEXT processing. This change contributed a 30% performance improvement compared to using no additional threads.

Discussion

Inspired by currently available tools and with the objective of improving total throughput performance in NLP tasks, we developed Sophia as an expedient UMLS concept extraction annotator. The Sophia pipeline, as configured as a single end-to-end UIMA application for evaluation purposes significantly out performs both MetaMap and cTAKES in throughput. Components of each of the pipelines were examined to further elucidate the bottleneck components. For the Sophia Pipeline, assertion is the most time consuming component, even with some efficiency built around the ConText methods. Evaluation using the extrinsic task of finding clinical problems showed that Sophia has a similar over-all f-score to cTAKES, and out performs MetaMap. Furthermore, Sophia had a better recall than both cTAKES and MetaMap on this task.

The techniques within Sophia are an evolution of the techniques embedded within MetaMap. Sophia borrowed heavily from NLM's SPECIALIST Text Tools™, which were included in the first Java implementation of MetaMap Technology Transfer (MMTx). The Text Tools included the lexical lookup, the part-of-speech tagger and the phrase identification components of MetaMap. Sophia's lexical lookup is a direct descendant to the Text Tools™. Sophia differs from MetaMap in that it does not do the brute force mapping that was included in MMTx; it keeps only the longest spanning matches from the variant table, that is, it does not compute partial matches; it does not do part-of-speech tagging or phrase identification; and it combines the concept information within the variant and lookup table, rather than relying on tables to do the lexical lookup, then lookup in tables to find the variants, followed by lookup in tables to find the concept information for each match.

MetaMap's strength is in the evaluation and ranking it achieves once candidate concepts are pulled from the index. It is in this evaluation where MetaMap churns away. It is the most computationally expensive part of the algorithm, by far. Neither Sophia nor cTAKES includes such an evaluation component. This evaluation component allows MetaMap to retrieve and rank quality near matches that don't quite cover, or cover too much (partial matches, concept gaps and over-matches) from the corpus text. Neither cTAKES nor Sophia retrieves partial matches, concept gaps or over-matches. This increases coverage for information retrieval tasks. If one limits to exact matches (those that have 1000 as the final mapping score within MetaMap), results, in theory, should be equivalent. MetaMap's ranking takes into account the cognitive distance it took between seen text and a UMLS Concept. Sophia retains the cognitive distance but does not use it. Even with this ranking mechanism, MetaMap still returns ambiguous concepts when the ambiguity is at the lexical level. Embedded within MetaMap are techniques to limit ambiguity where it can without having to call upon the services of Word Sense Disambiguation (WSD). Such techniques include stop word filters, the ability to filter by semantic type, truncating by frequency hit cut offs and the like. MetaMap has an add-on WSD service to help ameliorate this facet as well. The Sophia pipeline considers all its ambiguous retrieval results to be a WSD issue that should be addressed properly in a downstream process or annotator, where both local and global context can be utilized.

In comparing Sophia, MetaMap and cTAKES methodology, the Sophia annotator shares many attributes with the cTAKES dictionary lookup annotator, and the *Dictionary Lookup Annotator UMLS* aggregate engine. Both are UIMA based, both include similar windowed lookup techniques. Whereas cTAKES uses LVG's normalization to a normalized index of UMLS strings, Sophia looks up unadulterated tokens in Sophia indexes that are generated via LVG's fruitful variants flow using UMLS Strings as its input. This algorithm was developed as part of MetaMap[1], and had become an LVG function in the early 2000's. Sophia relies on a post filtering of this flow to prune off unnecessarily aggressive or likely to be fallacious variants.

CTAKES matches to the SNOMED vocabulary subset of the UMLS. Sophia indexes to the level 0 + 9 UMLS terminologies which include MeSH and SNOMED. Both the cTAKES and Sophia pipelines were designed for use within the clinical setting, and as such, utilize tokenizer, sentence and section annotators and downstream annotators to add negation, conditional, hypothetical, or not-relating-to-the-patient context.

Sophia relies on sentence annotations created from upstream annotators within a UIMA pipeline. In this way, Sophia is similar to the cTAKES Lookup annotator functionality. Sophia adds *Clinical Statements* filled with *CodedEntries* to each annotated document. Clinical Statements are roughly equivalent to cTAKES *EntityMentions* and *EventMentions*, and even more roughly equivalent to MetaMap's final mappings. A *CodedEntry* is equivalent to cTAKES' *UMLSConcept*, and roughly equivalent to MetaMap's *Candidate Concept*.

Whereas MetaMap and cTAKES formulate candidate phrases for lookup using similar techniques, Sophia does not. MetaMap and cTAKES break text into phrases before concept lookup by first tokenizing into sentences, then doing part-of-speech annotation, followed by phrase detection prior to phrase-to-candidate concept lookup. Sophia, in contrast, relies on upstream annotators to label sentences. Sophia looks up longest matching terms within the sentence, similar to MetaMap's lexical lookup algorithm. Like MetaMap's lexical lookup, Sophia's term lookup uses a longest spanning match, which is an evolution of the algorithm embedded in the SPECIALIST Text Tools, which was embedded in MMTx, the java implementation of MetaMap. It should be noted that MetaMap has the ability to do both longest and shortest spanning matches. Sophia's lookup mechanism has two new attributes not found in the SPECIALIST Text Tools. First, it starts its matches from left to right, using an index where the token keys are reversed. This is done to favor picking up right headed noun phrases. Second, UMLS Concept information is embedded within the indexes, so further lookup is not needed.

Whereas MetaMap first looks up terms within the SPECIALIST Lexicon, then uses those terms for phrase barrier determination, then looks up the phrase tokens to find UMLS concepts from an index of UMLS Concept variants, Sophia looks up terms in the UMLS Concept variant table directly without need for part-of-speech or phrasal boundaries.

An early UMLS principle was to keep knowledge resources like the SPECIALIST Lexicon and the UMLS Metathesaurus separate to keep semantic components out of the SPECIALIST Lexicon and to keep syntactic components out of the Metathesaurus. This allowed maintenance cycles for these resources to be de-coupled. This principle carried forth to continue to decouple the syntactic processing from the semantic processing via first finding terms, , then phrases, then concepts within those phrases, as MetaMap, and to some extent, cTAKES does. Finding multi-word terms, particularly if they come from the SPECIALIST Lexicon, and particularly if they decrease ambiguity, greatly helps phrasal boundary detection from part-of-speech taggers that tag at the single token level of granularity. MetaMap uses the MedPost part-of-speech tagger, which was trained using a corpus that had sparse coverage of the majority of multi-words found in the SPECIALIST lexicon, and from the UMLS Metathesaurus. Term lookup followed by part-of-speech tagging on those words and terms within MMTx is used to make phrasal barrier decisions.

Sophia does away with the need for phrases and consequently, parts-of-speech. The term indexes and the UMLS Concept information are folded into one, indexed off the same key. That's not to say that other annotators shouldn't be run to keep around both part-of-speech and phrasal information. A consequence of ignoring phrasal boundaries within Sophia, longest matching terms that span across phrasal boundaries are retrievable within Sophia, but would be missed via MetaMap and cTAKES.

Although not incorporated here, the Sophia Pipeline, in practice, is often augmented with a local concept annotator combined with a file of local terms and their categories to address tasks where the UMLS lacks coverage. This is a capability included within the v3NLP framework that is not easily replicated within MetaMap or cTAKES.

Future Work

Future versions of Sophia will be integrated into v3NLP's scaled-out architecture, where the slower annotators are replicated as multiple instances behind services, and called via wrappers around clients to these services. The next version of Sophia will be updated to the latest version of the UMLS.

The next version of the Sophia pipeline will include annotators to filter out non-salient false positives including the units of measure, dates, and the like that MetaMap effectively filters out. Further analysis will be spent to understand those multi-word instances that Sophia missed, and vice versa.

Assertion attribution will be looked at further to choose what assertion modules perform the best in respect to time and efficacy.

There is on-going interoperability work to enable v3NLP annotators, Sophia being one, with cTAKES to enable the use of cTAKES annotators within v3NLP and vise-versa.

Availability

Sophia is available via an Apache license, and is distributed from the http://v3nlp.utah.edu/sophia. End users are required to validate their own UMLS license via an application that validates UMLS licenses through the National Library of Medicine's UMLS Terminology Services (UTS) before unlocking the content of indexes that contain UMLS derivative content within this distribution.

Conclusions

Sophia has been developed as an expedient UMLS concept annotator. The Sophia pipeline out performs both cTAKES and MetaMap in recall and has an f-score that is only 0.04 different than cTAKES. The pipeline runs 18 times faster than cTAKES and 7 times faster than the scaled-out MetaMap services. For those information extraction applications where fast throughput is needed and/or recall is favored over precision, the Sophia pipeline is an acceptable solution.

Abstract

Unintentional injury is a leading cause of death worldwide, and the number one cause of child death in the United States. The American Academy of Pediatrics promotes safety recommendations to decrease child injury risk, however the majority of educational programs delivering these strategies are school-based or in community campaigns. Mobile technology provides an opportune platform to deliver pediatric injury prevention programs given its massive global reach and underrepresentation within the current mobile health market. This paper describes the development of iBsafe, a novel mobile safety game application designed to prevent injury in 5- to 6- year old children. Our multidisciplinary team utilized a step-wise approach to create an innovative child game application which is based in behavioral theory and promotes evidence-based safety recommendations. Results and future directions for iBsafe aim to interactively educate children on how to be safe and ultimately improve their safety behaviors.

Introduction

Unintentional injury is a leading cause of death worldwide[1] and in the United States (US), the number one cause of child death and nonfatal injury.[2] Each year, nearly 10,000 children under 18 years of age die from injuries, and over 8 million suffer non-fatal injuries.[2,3]

Haddon's Matrix – a conceptual framework of etiologic factors – has been used to guide unintentional injury control.[4] Using this framework, injury experts have identified factors that contribute to the risk of unintentional injury and aid in developing evidence-based and expert-guided strategies to decrease this risk. The American Academy of Pediatrics (AAP) and other safety organizations espouse such prevention recommendations, which are often aimed at parents and children, and are categorized by the child's age or the cause of injury.[5] Child safety programs designed to promote these recommendations are typically delivered in classroom curricula or community campaigns which can be time consuming, costly and often have narrow scope and limited penetration.

More recently, there has been growing support and evidence for the use of behavioral science theories and models to help understand and prevent injury risk.[6-8] Computers or games that utilize some or all of these tenets within their design and development have the potential to educate and change the behavior of the user.[9-11] Within the field of health care, a variety of game interventions have been effective in teaching medical education,[12] and interactive games have increased child understanding and management of the heath conditions.[13]

The rapidly expanding field of mobile technology is a potential platform to deliver injury prevention programs with extensive reach. Currently, there are over 6 billion mobile device subscriptions worldwide, representing nearly three-quarters of the world's inhabitants.[14] In the US, approximately 240 million individuals use mobile devices and nearly 160 million people own smartphones.[15] Half of all children under 9 years of age have access to mobile devices in their home and nearly 30% of US parents download applications for their children to use. Additionally, the majority of child time using these devices is spent playing games,[16] presenting an unprecedented opportunity to seed injury prevention messages in the form of game play.

Mobile health (mHealth) is increasing in popularity with health organizations, providers, and consumers. In 2013, there were more than 40,000 health-related applications in the Apple iTunes App Store representing an estimated 660 million downloads. Of these, 16,000 were consumer/patient-targeted healthcare applications, ranging in services from prevention and wellness, diagnosis, finding health care providers, health care education, prescription refills and compliance. Furthermore, 50% of consumer oriented healthcare applications targeting specific demographic groups were for children's health. [17]

Despite this rapid growth of mHealth and the burden of child unintentional injury worldwide, mobile applications related to injury prevention remain underrepresented and few interactively address child injury prevention. Thus the goal of this project was to systematically develop a mHealth tool for child unintentional injury prevention. Given that most children access mobile devices to play games, we believe there is a significant need to develop a safety game that gives children vital prevention information and offers an alternative to other non-educational mobile game play. We aimed to develop this mobile device game application, founded in behavioral theory, using a multidisciplinary team and evidence-based AAP recommendations.

Application Development

Development Team

A multidisciplinary team of experts developed this intervention. Our team included: three pediatricians (two child injury prevention experts [CD and WP] and one child prevention intervention expert [MMG]); a child behavior specialist with expertise in prevention programs for children [RA]; a professional graphic designer and former industry child game programmer [BM]; a human-computer interaction design professional [HY]; two informatics and design experts [JD and BJ]; two masters-level design students; an educational professional specializing in learning with gaming education and multimedia applications [JE]; and a media design/ software development company specializing in interactive technologies for health care, behavioral research and education [TJ].

Behavioral Theory

Social cognitive theory (SCT) is a behavioral theory which has been used within the field of injury to help guide intervention designs and measures.[6,7] SCT theorizes that to understand, predict and change human behavior, one must look at the interaction between the person, environment and behavior. It posits that individuals learn vicariously through observing and modeling other's behaviors and through social reinforcements. For this modeling to be effective the behaviors must keep the observer's attention and be memorable; the ability of the observer to adopt the behaviors relates to his/her self-efficacy and motivation. [6-8,18,19]

Based on these premises, we developed a modified conceptual model of SCT (Figure 1) to link child unintentional injury prevention and gaming. We proposed that central to the prevention of child unintentional injury are the child's safety knowledge and applied behaviors, both of which could be achieved within the our mobile safety game experience and further translated to the environment by the reciprocal nature of the constructs. Specifically, the interactive game centers around three main determinants: Personal, such as knowledge and expectations; Environmental, such as the influence of others and the environment; and Behavioral, such as skills and practice. The interactive game creates an engaging Environment in which the child learns vicariously through their character's behaviors (modeling) and the subsequent rewards and consequences (reinforcements) of these behaviors. Self-efficacy is achieved within the simulated Environment as the child becomes more knowledgeable about safety, which translates to the child's real-life Personal knowledge and expectations. Motivation to adopt safe Behaviors in the real world is reinforced by the child's experiences within game play itself.

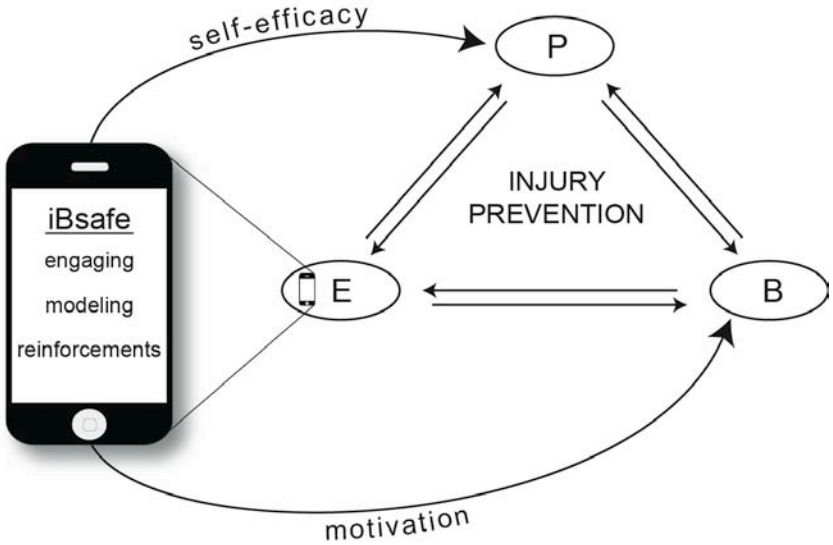

Figure 1. iBsafe Conceptual Model

User Group and Injury Mechanism Selection

There are many different causes of child unintentional injury and associated risks vary by child age and developmental capability. Ideal games should be developed with these factors in mind. Our first priority was to identify our user group and specific injury causes we aimed to address.

Knowing that younger children bear much injury burden, we chose to develop a game for kindergarten-aged children. This 5- to 6-year-old population represents approximately 500 deaths and over 700,000 nonfatal unintentional injuries in the US each year.[2,3] Of these, about 2,000 are seen in the nation's emergency departments (ED) every day and their associated annual direct and indirect costs are estimated to be nearly $3.5 billion.[20]

Two of the top ten leading causes of non-fatal injury in 5- to 6-year-old children are bicycle injuries and dog bites.[3] Compared to the rate of these injuries among the general population (17.3

per 1,000 and 11.5 per 1,000, respectively), bicycle injury and dog bite rates among 5- to 6-year-old children are nearly double (36.7 per 1,000 and 22.6 per 1,000, respectively).[3] Together these two injury mechanisms account for over 50,000 ED visits and 1,000 hospitalizations of 5- to 6 year-old children each year, with annual costs approximating $250 million.[20]
Therefore, our team elected to address the topics of bicycle safety and dog bite prevention in our child safety application. We created and named our application iBsafe for "Interactive Bike and Bite Safety".

Injury Content
Many AAP bicycle injury and dog bite prevention recommendations exist for 5- to 6-year-old children.[21-25] These recommendations are expert-guided or supported by scientific evidence. Using these recommendations and the existing literature as a guide, we selected 10 specific safety strategies to be the learning objectives of the iBsafe game (see Table 1). These objectives are concepts or actions that a 5- to 6-year-old child is capable of independently understanding and performing.

Table 1. Injury prevention strategies.

Bike	Dog
Always wear a helmet	Never approach or touch a dog that is eating or chewing on bones/toys
Always wear helmet on the top of head	Never approach or touch a dog that is caring for puppies
Always click helmet straps under chin	Never approach a dog that is behind a fence
Never ride on the street	Never approach a dog that is tied
Always ride with an adult	Never run from an unknown dog

Mobile Device Output
In addition to delivering injury prevention strategies, we aimed to design and program iBsafe to facilitate the capture and recording of game scores and frequency of use. Such data is stored within the Apple iPod touch® device's "sandbox" which can be downloaded to a host computer or uploaded to a server.[25] This step would allow us to better understand and analyze player game utilization during iBsafe testing.

Game Design and Application Programming
Design and programming of the game application occurred from November 2011 – October 2013. The principal developer (CD) oversaw all phases of iBsafe development. Collaborators and consultants in their respective areas of expertise were involved throughout the entire process. The following stepwise framework was used:

1) *Surveying current game applications and vetting potential game designs (~ 1 month).* In this step, our group reviewed multiple game applications on the market for children aged 3-9 years. We assessed applications for playability of our ultimate user group, analyzing games for the typical 5- to 6-year old child's development and comprehensibility. From this step, we selected a game design that would allow the player to use screen-touch and device motion play. This review also revealed that no game applications addressing child bicycle or dog bite

safety in our user age group were publically available on the Apple iTunes App Store.

2) *Determining the schematic design on paper (~2 months).* This step entailed the creation and review of our game's schematic design. During this iterative process, we identified and selected character and player graphics; design of game play using streets, sidewalks, houses, yards and dogs; and the visual scoring schema.

3) *Creating the game script (~ 1 month).* Game script creation was a concerted process harmonizing the premise of our conceptual model, teaching the injury prevention strategies and interactively engaging the user group based on their level of cognitive development. The script was designed to emphasize injury prevention strategies multiple times while engaging the user with different scenarios and multiple levels of play.

4) *Programming initial prototype (~8 months).* Programming of the initial prototype was an iterative process. Given that our ultimate user group is a young child, we chose to develop the game for an iPod touch using the iOS platform. Unity game development software was used for game programming. We held regular meetings to assess the current status of the prototype, and ensure consistent progress and maintenance of a common vision and goal.

5) *Prototype completion, incorporation of device output, and internal usability testing (~12 months).* Final programming of the prototype, completion of schema, and incorporation of device output was led by the principal developer and our mHealth developer company. Internal usability testing was performed by mHealth experts, select individuals in the team, and children aged 5-6 years. We asked individuals to "think-aloud" during internal usability testing and asked the children to give general game feedback.

Results and Discussion

We have developed iBsafe – a novel interactive mHealth game application for child safety. The development of this application used a unique multidisciplinary approach involving experts in the fields of child injury prevention, child behavior, intervention development, informatics, game education, design, programming, and usability. Furthermore its development was based on our innovative iBsafe conceptual model, which posits that unintentional child injury prevention requires children to have safety knowledge and apply those behaviors, both of which can be modified in the game experience and translated to real environment. Specifically, the interactive game provides a safe, engaging environment where the child learns by being presented with bicycle and dog bite risks; knowledge and behaviors learned during game play can be further translated to real life.

Figure 2. iBsafe game start screen.

Figure 3. iBsafe character selection screen.

The full iBsafe (Figure 2) game experience entails 67 scenes, 5 levels and 1 bonus level. It commences with the user selecting one of the 6 child characters to represent the player for the remainder of the game (Figure 3). Throughout the game, the player interacts with multiple simulated environments testing and teaching the evidence-based bicycle safety and dog bite prevention strategies. These environments include: a simulated street environment, inside and outside of homes, a dog shelter, and a park.

Specific to bicycle safety, the player is encountered with challenges in which he/she must prepare to and safely ride a bike, recognize characters that are not riding safely, and finally teach others how to be safe while riding bikes. Figures 4 and 5 are example bike safety screen shots.

Figure 4. iBsafe bike safety screen 1.

Figure 5. iBsafe bike riding screen 2.

Specific to dog interactions, the player encounters challenges in which he/she must choose safe interactions when exposed to both familiar and unfamiliar dogs in different scenarios (such as eating, behind a fence or tethered, caring for puppies), as well as situations in which he/she must teach others how to be safe around dogs. Figures 6 and 7 are examples dog safety screen shots.

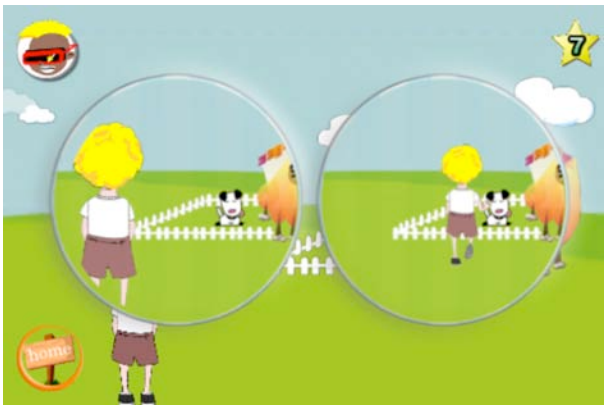

Figure 6. iBsafe dog safety screen 1.

Figure 7. iBsafe dog safety screen 2.

Scoring for game play involves attaining points (represented by stars). There is no maximum score threshold within game play. To gain points and advance to the next level, the player must answer challenges (questions) correctly and perform tasks safely. The player gains one point for every correct answer and loses one point for every incorrect answer; the player gains points for riding their bicycle safely and loses points for riding the bicycle unsafely. The game ends when the player completes all 67 scenes or if the player is hit by a car while riding the bicycle.

Data surrounding every point gained or lost during game play is tracked and can be uploaded as a comma separated value file from the device or onto a server. These data include: a time stamp, character chosen, game and level, current game score and device game high score (see Figure 8.)

Game Number	Level Name	Time stamp	Level	Character	Attempts	Successes	Current Score	High Score
1	Get Ready to Ride	11/19/2013 21:08	0	character3	FALSE	1	0	0

Conclusions and Future Directions

We developed iBsafe – an interactive mHealth application – to teach and promote child safety. Development of this application is innovative in four distinct ways. First, it addresses two major child injury mechanisms (bicycle and dog bites injuries), for which there is a significant prevention need. This need is evidenced by the burden of these injuries among children and their associated costs. Second, it utilizes an innovative approach – an interactive game developed and founded in behavioral theory – to educate well-established safety skills, which allows the child user to explore and encounter simulated scenarios of risk in a safe environment. Third, it employs the rapidly expanding technology of mobile devices - specifically applications - to deliver the injury prevention intervention, which can be easily disseminated and applied on a large scale. Lastly, to our knowledge, it is the first interactive mobile device game application aimed at injury prevention for kindergarten-aged children. Given the preponderance of US children using mobile devices to play games, we believe there is an extraordinary market for a safety game application that gives kids vital prevention information and is an engaging alternative to other non-educational mobile game play.

Future directions for iBsafe entail testing it for effectiveness and acceptability in our user population and subsequently expansion into an iBsafe mHealth application series to include other leading causes of child unintentional injury. Our hope is that the iBsafe mobile application game series will interactively educate children on important injury prevention strategies, be supported by sound, scientific evidence, and ultimately, help keep kids safe from harm.

Abstract

Patient engagement has been identified as a key strategy for improving patient outcomes. In this paper, we describe the development and pilot testing of a web-based patient centered toolkit (PCTK) prototype to improve access to health information and to engage hospitalized patients and caregivers in the plan of care. Individual and group interviews were used to identify plan of care functional and workflow requirements and user interface design enhancements. Qualitative methods within a participatory design approach supported the development of a PCTK prototype that will be implemented on intensive care and oncology units to engage patients and professional care team members developing their plan of care during an acute hospitalization.

Keywords: participatory design, plan of care, communication, health information technology, patient engagement, nursing informatics.

Background and Significance

Acute care hospitals have been long recognized as complex, dynamic, and fast-paced environments characterized by suboptimal communication.[1, 2] Providing tools to support communication, patient activation and engagement can improve patient outcomes and lower healthcare costs.[3] Engaging patients in their recovery plan and providing them with information they need to be informed participants in that plan are key strategies for adverse event and error prevention.[4] The Meaningful Use legislation includes incentives for providing patients with timely information including the use of secure electronic messaging for providers to communicate with patients about their health status.[5] However, there is limited literature describing tools to activate patients and engage them in their plan of care during an acute hospitalization.

In our previous work we found that by providing all care team members including patients and family with information about a patient's risk for falls and a personalized prevention plan, the rate of patient falls was reduced by 22%.[6] Our team has also found that effective patient education can reduce the incidence of preventable adverse drug events.[7] Others have found that interactive educational tools can improve patient adherence with their treatment plan and improve patient outcomes.[8] Based on these findings, in prior work our team conducted focus groups and interviews with patients, family caregivers, and professional providers to identify the core set of information needed to engage in their recovery during an acute hospitalization[9] and determined the following core information requirements: 1) plan of care, 2) tailored patient education, 3) communication of safety alerts, 4) diet restrictions and 5) medications. We built an electronic Bedside Communication Center (eBCC) prototype to activate patients and to bridge the communication gap between the healthcare team and patients during an acute care hospitalization. We then conducted initial usability testing with hospitalized patients on medical units and found that overall patients and family found the eBCC both useful and easy to use.[10] However, they identified some gaps in the functionality including the ability to message their care team and the ability to directly participate in developing the plan of care. The purpose of this paper is to describe the participatory design process that our team is using to engage patients, family, and health care professional stakeholders in the development of a patient-centered toolkit (PCTK) that will be implemented on intensive care and oncology units to engage patients and family in their plan of care during an acute hospitalization. The research questions are:

1) What are the workflow requirements needed to support patient involvement in developing the plan of care and direct communication with providers?

2) What are the content/user interface requirements needed to support patient involvement in developing the plan of care and direct communication with providers?

AHRQ Conceptual Framework of Patient and Family Engagement

This project is informed by the AHRQ conceptual framework of Patient and Family Engagement[11] that defines the organizational and individual characteristics and behaviors that are antecedents to patient engagement. The framework identifies anticipated outcomes of patient engagement needed to ultimately achieve the triple aim of improving the patient experience, improving the health of populations, and reducing the cost of healthcare.[12]

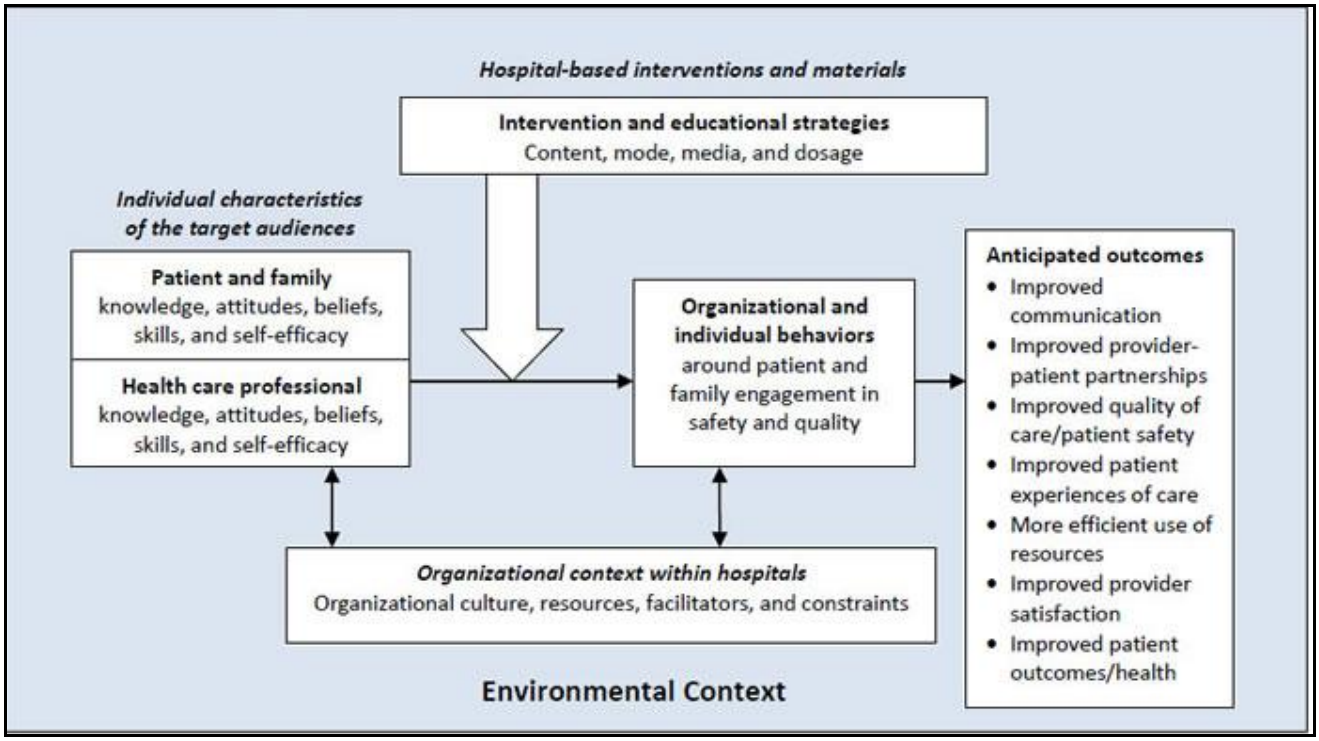

Figure 1: AHRQ Conceptual Framework of Patient and Family Engagement

According to this framework, the PCTK intervention will be effective if it facilitates patient, family, and health care professional engagement in the specific behaviors needed to support safety and quality. Therefore the PCTK should focus on organizational and individual behaviors (patient, family and health care professional) that are acceptable to each stakeholder and that are feasible within the hospital setting. Engagement with stakeholders is needed to identify the specific behaviors that are acceptable and feasible and to develop a PCTK that can be used by all stakeholders in the context of acute care workflows.

Research Methods

Our specific aim was to identify the workflow and user interface requirements needed to support patient involvement in developing the plan of care and communicating with providers related to that plan during an acute hospitalization. We used an iterative participatory design approach to develop the plan of care and provider communication features of the PCTK. The study was reviewed and approved by the Partners HealthCare Human Research Committee and was conducted at Brigham and Women's Hospital (BWH), an academic medical center in the Northeastern United States. We used a combination of individual interviews and group interviews to engage patients, family, and professional health care team members in development and refinement of a series of prototypes. Participants included former patients and their family members, and nurse and physician providers who cared for patients on the intensive care and oncology units at BWH. Interviews were conducted at the bedside with hospitalized inpatients and family members. Group interviews were conducted with discharged patients and family and with professional care team members in conference rooms at BWH. Inclusion criteria for patients included current or past inpatient admission (patient or family member) in an intensive care or oncology unit or a professional care team member working on those units, over 18 years of age, awake and alert, able to understand and speak English, able to provide feedback on their experience and on the PCTK prototype.

Iterative Participatory Software Development. We started with a PCTK prototype that we developed previously for patients hospitalized with an acute medical condition.[9, 10] An iterative participatory software development process (see **Figure 1**) was used to engage stakeholders in developing a series of prototypes; each incorporating what we learned related to the user's (patient/family and professional care team member) role and behaviors in plan of care workflow and associated communication. Through this process we aimed to identify workflow and system usability constraints that were then addressed in subsequent prototypes to produce a PCTK

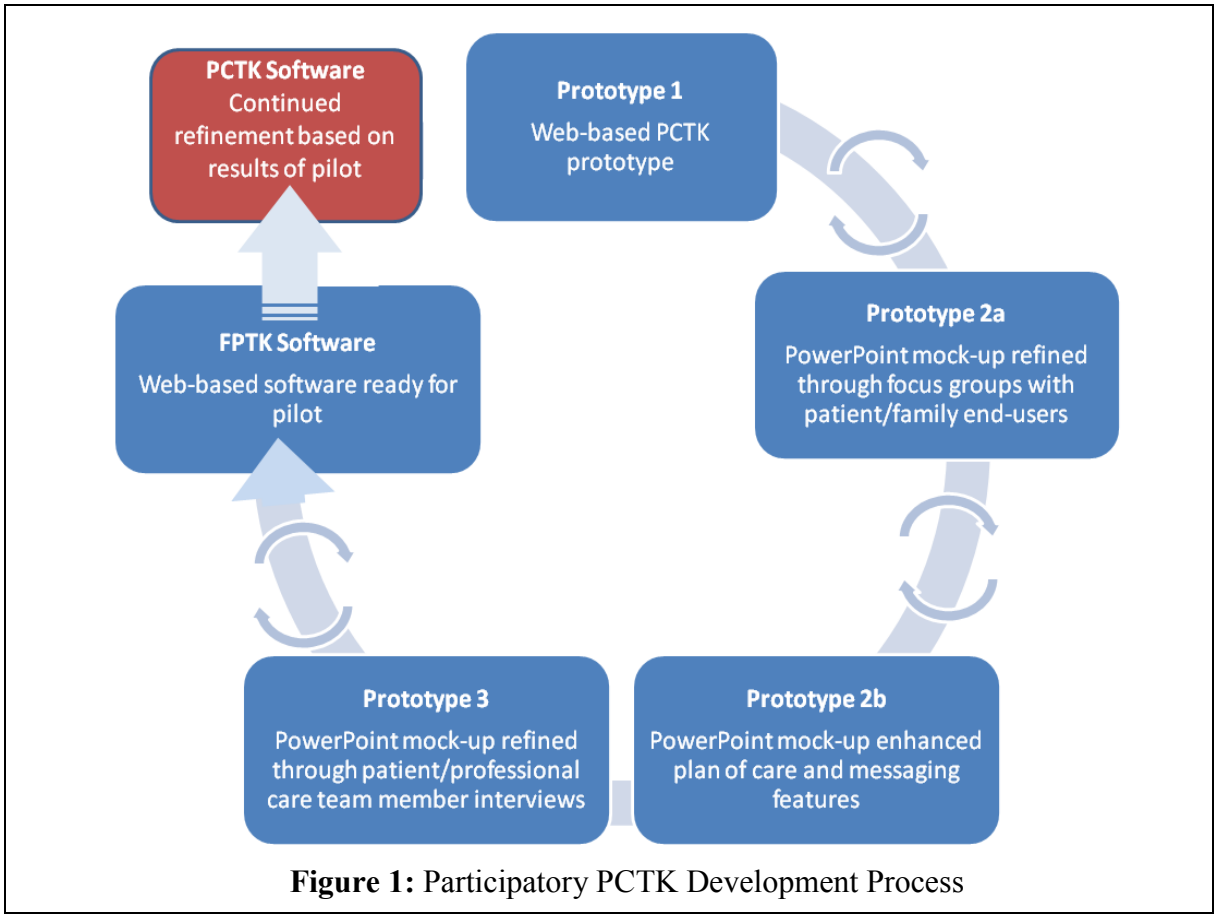

Figure 1: Participatory PCTK Development Process

that would enable patients, family, and professional care team members to collaborate and communicate in regards to the plan of care.[13, 14]

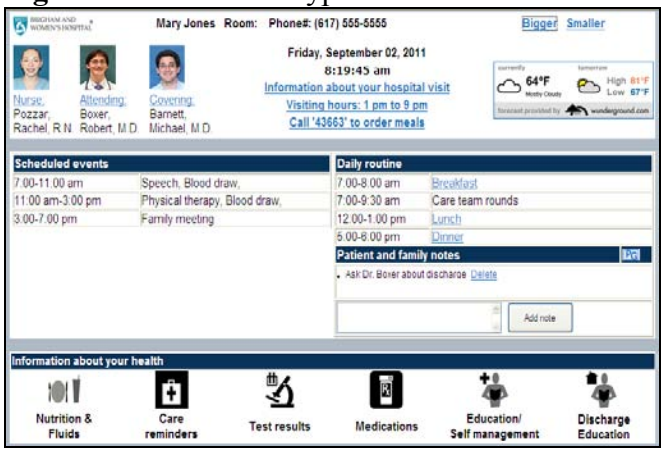
The types of interviews conducted to engage end users in development and refinement of the PCTK are as follows:

1. *Bedside interviews with patients and family (Round 1):* We started with the prototype developed in our previous research (*Prototype 1* see **Figure 2**).[9, 10] Prototype 1 was accessed via the internet on a secure mobile tablet and tested for usability at the bedside with hospitalized medical patients and family members.

2. *Patient/Family Advisory Council group interview:* Group interview with former oncology and intensive care patients and their family members using PowerPoint mock-ups (*Prototypes 2a, 2b*) followed by individual interviews to verify requirements and user interface enhancements.

3. *Professional care team group interviews:* Series of interviews conducted over 6 months with professional care team members to identify existing workflows and opportunities for integrating the toolkit into workflow and to identify opportunities for secondary use of data to populate the PCTK. PowerPoint mock-ups (*Prototypes 2a, 2b*) and the web-based software (*Prototype 3*) were informed by these interviews.

Figure 2: PCTK Prototype 1



4. *Bedside interviews with patients/family (Round 2)*: Individual interviews were conducted on oncology units using an interview guide and Prototype 3 to identify patient/family preferences related to participation in development of the plan of care and to vet the features and workflows defined by professional providers. Prototype 3 was accessed via the internet on a secure mobile tablet.

5. *Meetings with clinical and administrative leaders and stakeholders:* In addition to engaging, patients, family, and professional providers, we met with clinical and administrative leaders and stakeholders to ensure that our project fit in with the BWH organizational informatics strategy.

Interview guides were used to structure each group and individual interview to ensure that outstanding questions related to plan of care workflows, communication and the user interface were addressed. Investigators took detailed notes during the interviews and debriefed at weekly research team meetings where notes were reviewed, emergent themes identified, and requirements refined. Changes were incorporated into PowerPoint mock-ups and iteratively revised by the research team. Mock-ups were then shared with interview participants to validate new requirements and to vet the refinements made to the user interface.

Results

1. *Bedside interviews with patients and family (Round 1):* Eight patients and three family members participated in the first round of bedside interviews. Sessions were conducted on general medical units. While detailed results have been reported elsewhere[10], two related findings were that patients and family requested additional functionality to support their participation in the patient plan of care and for communicating directly with providers on issues related to their plan.

Resulting Mock-up: Distinct plan of care and communication features added to the prototype.

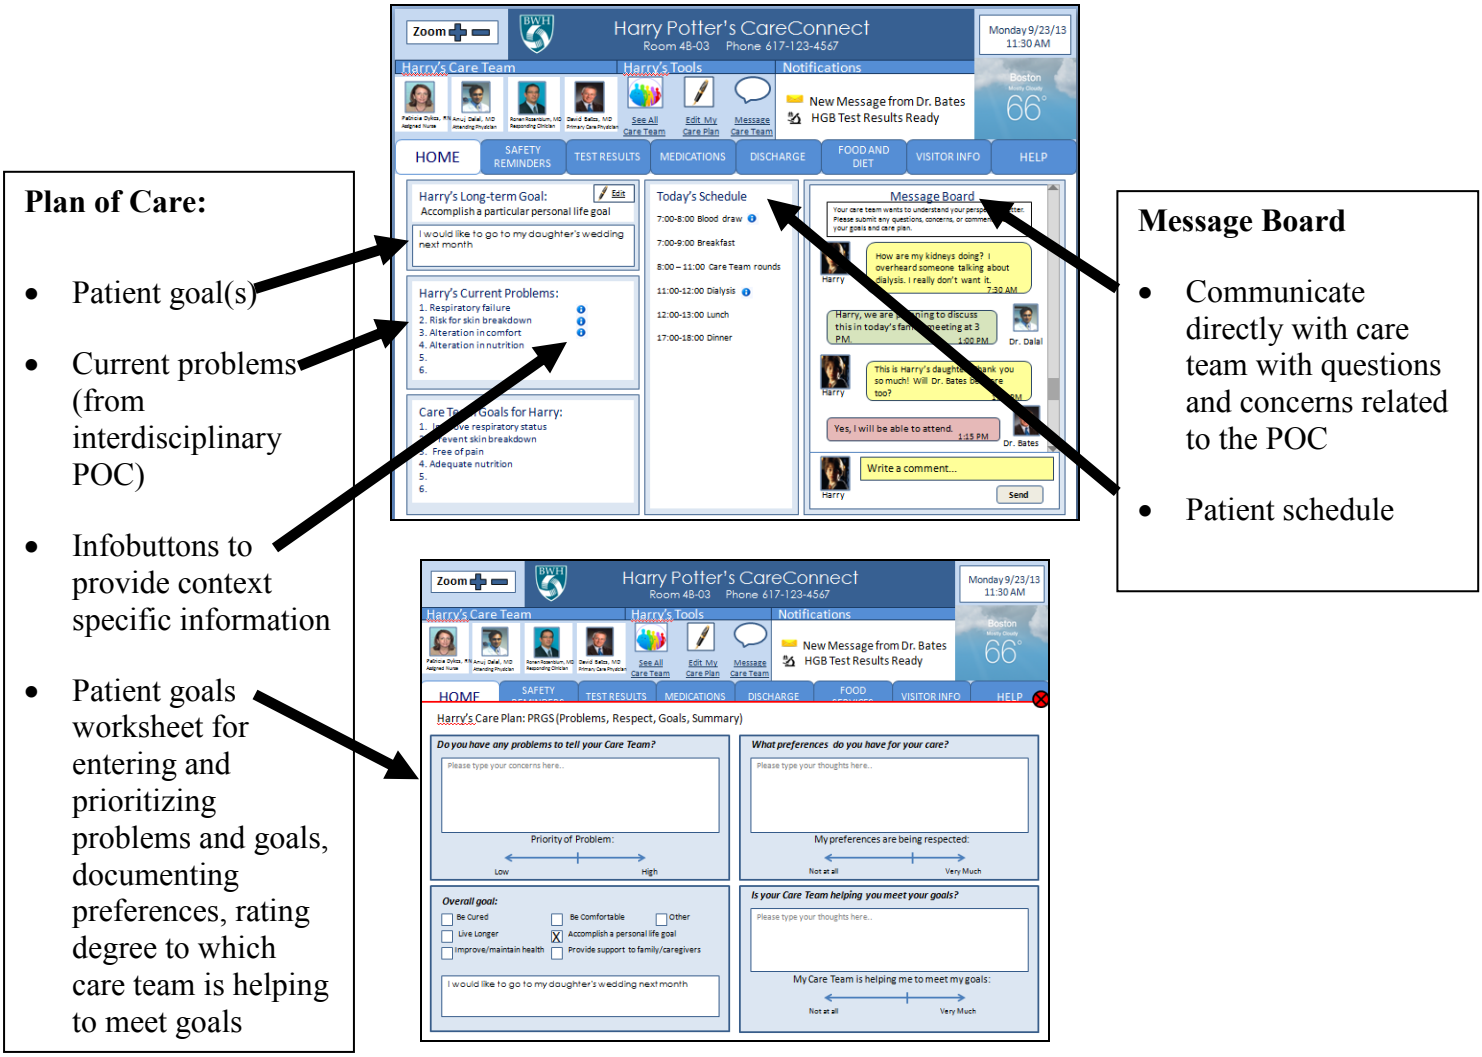


Figure 3: PCTK Prototype 2

2. *Patient/Family Advisory Council group interview:* Discharged patients and family members participated in a group interview and follow-up individual interviews. A total of 12 patients/family members participated in the group interview. Individual follow-up was completed with one patient and one family caregiver to further explore and validate the themes identified in the group interview. While the majority of participants said that they liked the idea of providing patients and family access to information to help them participate in their POC, many said that the user interface was too busy and could be confusing for patients who are not technically savvy.

3. *Professional care team group interviews:* A total of 18 Nurses and 10 physicians participated in a series of group interviews. Overall participants said that they thought that the PCTK would be useful for some patients but they were concerned that the user interface would be difficult to navigate for older patients.

Resulting Mock-up: User interface simplified.

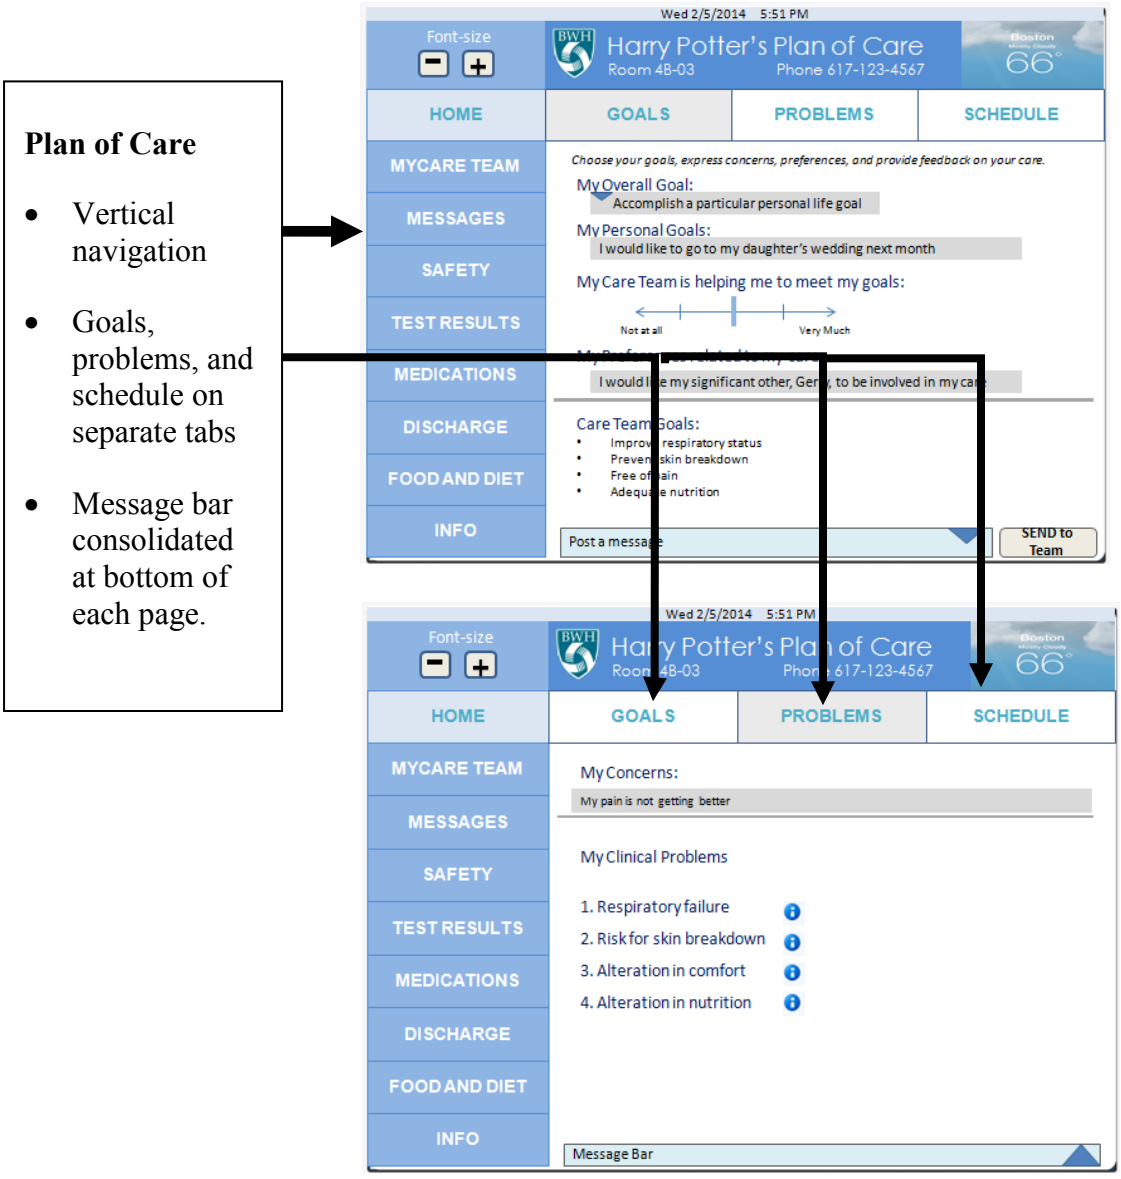

Figure 4a: PCTK Prototype 3 (Patient Goals and Problems)

Patient Schedule

- Consults, tests, meals, rounds
- Infobuttons to provide context specific information

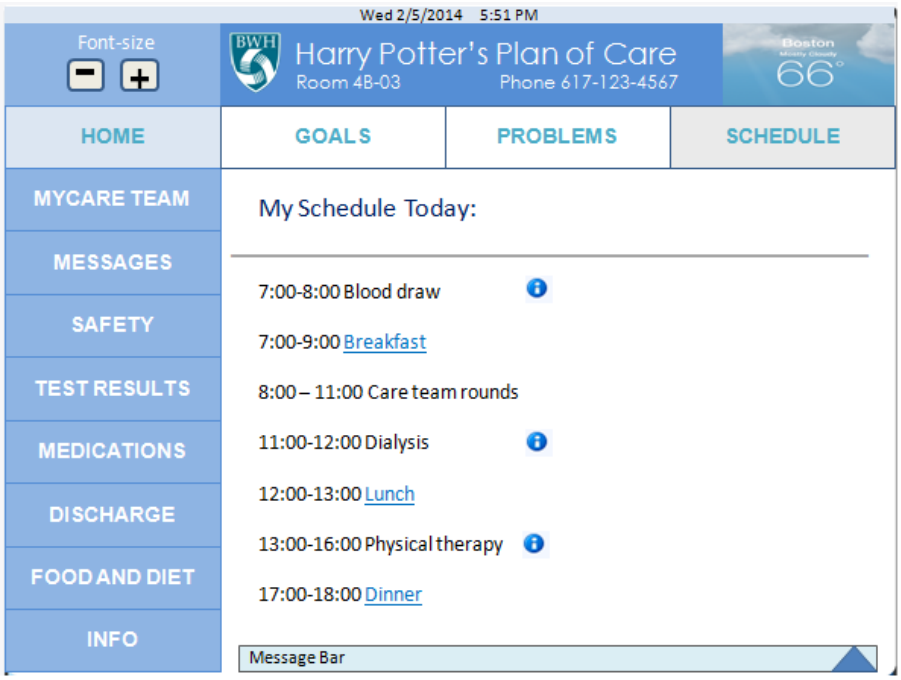

Figure 4b: PCTK Prototype 3 (Patient Patient Schedule)

4. *Bedside interviews with patients/family (Round 2)*: A total of five patients and two family members participated in the second round of bedside interviews. **Table 1** includes a summary of patient/family preferences related to participation in development of the plan of care and the features and workflows defined in group interviews by professional providers.

Plan of Care Elements and Workflow	Personally would use (n=7)	Thought others would use (n=7)	Favorite Element
Personal goals for hospitalization	86%	100%	
Feedback to care team on how well they are helping to accomplish goals	71%	100%	
Preferences for care	57%	100%	
Care team clinical goals	86%	100%	
Concerns related to care	71%	100%	
Medical problem list/Infobuttons	100%	100%	
Outpatient providers access to hospitalization plan of care	71%	100%	
Schedule	100%	100%	
Care team names/Pictures/Roles	86%	100%	14%
Messaging capability re: plan of care	86%	100%	
Safety dashboard/Infobuttons	71%	100%	
Test results/Infobuttons	100%	100%	28%
Medications/Infobuttons	100%	100%	28%
Food and Diet	100%	100%	
Discharge check list	86%	100%	
Did not answer	0%	0%	30%

Table 1: Patient/Family feedback related to Plan of care elements and workflow

5. *Meetings with clinical and administrative leaders and stakeholders:* Based on our meetings with clinical and administrator leaders stakeholders we learned that the 18 inch touch screen devices that we planned to install at the bedside were not feasible given the organizations plan to install bedside devices for providers as part of a larger electronic medical record implementation. We made a decision to go with mobile devices and to implement the PCTK on the iPad Air. As a result, we had to re-configure the user interface to optimize use on a mobile tablet device with a much smaller screen size. This new set of requirements led us to rework the user interface to accommodate the smaller screen size and to address the usability issues identified by patients, family, and professional stakeholders.

Discussion

We used an iterative participatory design approach to develop the plan of care and provider communication features of the PCTK for use with intensive care and oncology patients and family members. Participatory design is based on the classic principles of user centered design including: 1) Early focus on users and tasks; 2) Empirical measurement; and 3) Iterative design and development.[15] In our earlier work, we involved end users (patients and family members) and other stakeholders (professional care team members) in identifying the core set of information needed to engage patients in their plan of care.[9, 10] In this project, we continue to work with patients, family, and professional care team members to broaden our understanding of the information, tools and tasks associated with involving patients in the plan of care development process. Interestingly, through this approach, a set of information needs identified from our prior work was confirmed as useful by *all* patients and family members that participated in interviews: medical problem list, schedule, test results, medications, and food and diet. In addition to information needs identification, our approach enabled the identification of communication needs. We found that patients and family desire tools to help them communicate their goals, problems, concerns, and care preferences. They also would like to communicate directly with their professional care team members when questions and concerns about their plan of care arise. The rapid prototyping method was an effective way to involve patients, family and stakeholders in identifying usability problems and gaps in functionality that could be a barrier to use if not corrected. Our team has usability evaluation studies with *clinicians* to identify explicit information and communication needs in the context of a documentation workflow for goals of care[16]but to our knowledge this is the first study to define *patient and family* information and communication needs in the context of a documentation workflow for patient-centered care planning.

The initial prototype lacked specific tools to allow patients and family to document their personal goals, concerns, problems and preferences for care. It did include a space for patients and family to write questions that they could later share with the care team, but patients and family told us that this was insufficient; they wanted to directly communicate with their care team members. We added the care planning tools and a message board to the next prototype but soon learned from patients, family, and care team members that the user interface was too busy and that it would be difficult for older patients or patients who are not computer savvy to use. We simplified the user interface and the care planning tools in the next version of prototypes and have received positive feedback about patient and family intention to use the toolkit.

In addition to the feedback from stakeholders, our choice of hardware had an impact on the user interface. Specifically, changing from a mounted 18-inch touch screen device to an iPad Air forced us to reconfigure the interface from a horizontal to vertical tab, rearrange/remove content from the home screen, to rethink our navigation, and to leverage mobile optimized web-content. This was a difficult change to make but due to our ongoing communication with stakeholders, the issue was recognized early in the project when these types of changes could be made at a minimal cost.

In our most recent bedside interviews there was a limited sample of seven participants. Patients told us that they would use the care planning tools if they were available today and that they thought other patients would use it as well. Patients and family also reaffirmed the value of the additional information available from the PCTK such as pictures and roles of care team members, medications, test results, a discharge checklist, food and diet information, tailored information about their condition and their safety risks. Patients identified having access to their medications, schedule and laboratory results with Infobutton links to Medline Plus and other valid and reliable consumer literature as favorite features. One patient remarked, “I would like to have access to my medication

schedule when the nurses are giving me my medication because all of the medications have such strange names--- I like to keep track of what they are giving me". Another family member remarked, "This is useful because you know the first thing we do when we get home is Google what these things mean." We did have one patient who told us that although she could see how the PCTK could be useful for others that she would not use it. She said that she has the "right to ask for her paper chart" and that if she wanted information, she would request it. Given the emerging and mixed evidence of associations between engaged patients and a decrease in medication errors, these findings could inform our approach for measuring the impact of the PCTK on levels of patient engagement and adverse harm events.[17]

As we refine the PCTK software, we will continue to engage patients and family in using the software and in providing feedback on the user interface. As we have done in previous projects[18], we plan to implement the PCTK with our clinical nurse and physician champions and a subset of patients one month before go-live to ensure that we address any additional workflow or software issues before the tools are available to all patients on the oncology and intensive care units.

There are several limitations associated with this work. Our project is being conducted on a limited number of units in a single hospital. Our qualitative work has involved a limited number of patients and family and our findings may not reflect the views of other patients and family who have had similar or different experiences at BWH or at other hospitals. We consider ongoing patient, family and stakeholder involvement in the development of software as essential to designing software that is usable, useful and that will promote patient engagement in their plan of care. We will continue to engage patients and other stakeholders in this process as we further refine the PCTK software. In addition, we recognize that not all patients or family want to use computers or other devices to access information while in the hospital. Furthermore, some patients do not want to participate in developing their plan of care. The PCTK is meant to enhance current resources. A range of tools are likely needed to support hospitalized patients with different preferences and technical abilities.

Conclusion

While it is recognized that using technology to facilitate patient and family involvement in the plan of care could improve quality, safety and cost outcomes, their involvement to date is variable and evidence in this area is limited. Tools and processes are needed to provide hospitalized patients access to information about their condition and a set of tools to engage them in development of their plan of care. We found that many patients and family want to be knowledgeable about their condition and that they see value in tools that will help them to communicate their goals, problems, concerns, and care preferences. We also found that many patients, family members, and professional care team members are willing to participate in developing tools that will ultimately improve patient care and that they welcome the opportunity to make this contribution.

Abstract

The Reportable Condition Knowledge Management System (RCKMS) is envisioned to be a single, comprehensive, authoritative, real-time portal to author, view and access computable information about reportable conditions. The system is designed for use by hospitals, laboratories, health information exchanges, and providers to meet public health reporting requirements. The RCKMS Knowledge Representation Workgroup was tasked to explore the need for ontologies to support RCKMS functionality. The workgroup reviewed relevant projects and defined criteria to evaluate candidate knowledge domain areas for ontology development. The use of ontologies is justified for this project to unify the semantics used to describe similar reportable events and concepts between different jurisdictions and over time, to aid data integration, and to manage large, unwieldy datasets that evolve, and are sometimes externally managed.

Introduction

Public health surveillance, investigation and intervention are essential for the prevention and control of communicable and non-communicable diseases. Toward that end, every jurisdiction in the U.S. publishes a list of "reportable conditions" that function as a communication tool between public health entities and reporting entities. When a reportable condition is identified, reporters (e.g., hospitals, laboratories) are required to report the event to public health authorities [(1-5)]. Timely and accurate reporting is critical to identify, investigate, and control public health threats.

Accurate, timely and complete reporting of reportable conditions depends on reporters having correct and current information about a) the list of conditions that are reportable for the jurisdiction where they or their patients or clients are located, b) criteria that make a condition reportable, c) how quickly a report should be sent, d) what information should be included in a report, e) the preferred method to send a report, and f) where the report should be sent. This is referred to as the "who, what, when, where, and how" of reporting. Automated detection and electronic reporting depends on having this information available in machine-processable form to be stored as rules within a clinical decision support system, and used by an EHR or LIMS. Currently, this information is scattered across many different websites and documents[(2)]. It is difficult for human users to navigate, and the information is not usually presented in a manner suitable for machine-processing. The Reportable Condition Knowledge Management System (RCKMS) is positioned to provide a solution for this challenge by providing a single entry point to manage and access reportable condition specifications.

The RCKMS project is managed using a phased approach and is supported by the Centers for Disease Control and Prevention (CDC). The current phase (2014-2015) targets an authoring framework and administration screens that will capture reporting specifications, transform them to executable rules, and store them in an open source clinical decision support tool. Prior work included a view/query interface, accompanying printable reports, a user login/profile management interface, and subscription management capability. Jurisdictional reporting specifications were collected from six jurisdictions for three conditions, and default (or base content) was defined for 13 conditions, along with recommendations for resolving underlying issues in the Council of State and Territorial Epidemiologist (CSTE) Position Statements[(6)] that limit their use in defining computable criteria.

The RCKMS project promotes adherence to standards and reuse of existing authoritative resources. In keeping with this philosophy, the team participated in the Office of the National Coordinator's (ONC) Standards and Interoperability (S&I) Health eDecisions (HeD) pilot as an artifact provider. For the HeD pilot, an output file of reporting specifications was produced for pertussis reporting requirements that was both human-readable and machine-processable. Project members participate in other S&I initiatives related to the reporting lifecycle (e.g., Public health reporting Initiative, Data Access Framework, and Structured Data Capture), and the project will

continue to assess adoption options as standards evolve. Finally, RCKMS will use, not replace, existing value set repositories managed by the CDC (e.g., PHINVADS[7]) or the National Library of Medicine (e.g., VSAC[8]).

Objective

Given the breadth and complexity of the data needed to automate the reporting process on a national level, the RCKMS Knowledge Representation Workgroup was tasked to a) explore the need for ontologies to support RCKMS functionality, and b) develop recommendations for ontology development if indicated.

Methods

The RCKMS Knowledge Representation workgroup convened weekly to bi-monthly by phone and web conference from April through September 2013. The workgroup included members from various backgrounds representing those a) who may author content or query for and use the system output; b) who have developed knowledge management systems or components that may address parts of the overall problem; and finally, c) ontology developers from outside of the reportable condition domain.

The workgroup represented a diverse set of members from within and beyond the reportable condition community, enabling a wide variety of viewpoints to be expressed. The processes and resources currently involved with public health reporting, available tools, other exploratory projects, and the prototype RCKMS were presented to the workgroup. Meetings were recorded for those who missed them, and consensus was gathered iteratively through discussion and email. The resulting artifacts provide a comprehensive survey into the kinds of knowledge management needed to automate much of the currently manual processes.

Specifically, the workgroup participated in the following tasks:

1. *Evaluate Content:* The workgroup reviewed a variety of topics to understand the scope of content required and available for RCKMS, including the existing pilot application, other ontology and knowledge representation projects, related national initiatives, existing terminologies applications, and research that may contribute toward solving the defined problems. The workgroup surveyed the domain of public health reporting and described and evaluated the status of resources necessary for the RCKMS project.
2. *Define user stories and identify required data resource linkages:* The workgroup reviewed user stories submitted for the following stakeholders groups: Public Health epidemiologists at all levels of public health, knowledge curators or terminologists, clinicians, researchers, electronic health record vendors, laboratorians, and public health officials. The user stories were grouped according to the area of RCKMS affected. Next, the workgroup identified the need to represent linkages between resources necessary to meet the requirements observed in the user stories.
3. *Assess candidate knowledge domains for ontology development:* The following questions were developed by the workgroup and used to evaluate whether ontologies were needed to manage one or more of the sub-domains of information in RCKMS. Selected sub-domains were identified as candidates for ontological representation when the questions below were affirmative.

    - How complex are the relationships between the data?
        - How many different types of relationships exist in the area under consideration?
        - Is there a standard discernible structure that exists between the data?
            - Is there an inheritance of qualities between pieces of data?
            - Are there conflating ideas in the data that should be separated?
    - Is there a logical structure to the data?
    - Are users interested in questions that can more easily be answered if the data relationships are ontology-based?
    - Does the data change over time?
        - Are new concepts added that need to be classified?
        - Is the structure of the data rearranged over time?
    - Do we need to standardize the way more than one group describes or uses the data to share a common understanding?
    - Are there concerns about the quantity and maintenance of the data?
        - Is there sufficient data to warrant the time, effort and cost to implement an ontology?
        - Is maintenance of the data a manual burden/bottle neck?

    - Is the speed of response to change an issue?
- Does reasoning need to be done against the data structure?
    - Is there a need to enable tooling to validate rules?

4. *Develop recommendations:* Recommendations to advance the integration of ontologies into the RCKMS project were drafted based on input from the group, and refined iteratively over a course of meetings and comments submitted by workgroup members.

Results

Evaluate content

The workgroup identified domains of knowledge necessary for the RCKMS project and existing external coded resources for coded concepts represented in RCKMS. For each domain of knowledge, we described existing data sources, problems and recommendations for use and incorporation, and the relevance for RCKMS.

The workgroup identified the following three knowledge resources for RCKMS, representing data that needs to be managed for the project:

- *State reporting rules:* Reporting rules are available in HTML or PDF documents on state/county/city/tribal websites. While this information is authoritative, it is not computable. In addition, under the current paradigm, reporters are not notified of changes so it is time consuming and inefficient to remain current. Within RCKMS, there will be an authoring interface that will allow jurisdictions to manage their reporting specifications and make this information available in both human-readable and machine-processable formats. RCKMS will also support notification of changes to be sent to reporters who subscribe to receive changes for conditions or by jurisdictions.

- *Reporting logic for national surveillance:* The logic is available in Position Statements published as PDF documents on the CSTE website[(6)]. While this information can be used as a default to encourage uniformity, the reporting logic in the Position Statements is not uniformly adopted across jurisdictions. A detailed CTSE report concerning the content is available from the Public Health Data Standards Consortium[(9)]. Within RCKMS, criteria described in the Position Statements can be used as base content that can be copied and directly used by a jurisdiction, or modified to address jurisdiction-specific requirements.

- *Nationally notifiable conditions*: Once conditions are reported to a state or other jurisdictional public health agency, case definitions are used to determine which reports should be forwarded from the 'local' public health agency to the CDC for national surveillance. The logic for defining a confirmed or probable case (i.e. case definitions) for each condition tracked on a national level is available in HTML on the CDC website[(10)]. In addition, the coded concepts for these nationally notifiable events and other selected relevant value sets of coded concepts are available on the PHIN VADS website managed by the CDC[(7)]. While the nationally notifiable conditions are similar to reportable events, they do not include all conditions and criteria for reporting in a given jurisdiction. In addition, the conditions change over time, but the reasons for change and relationship between current and previous conditions are not captured.

The workgroup identified concepts in RCKMS that can be represented using coded values from existing external resources. For example, the following major domains of concepts, resources for coded values and key requirements were identified by the workgroup:

- *Clinical condition* (the name of a disease or health condition under surveillance)
    - Coded values: Subsets from SNOMED-CT® /ICD-9 CM/ ICD-10 CM
    - Requirement: Allow jurisdictional reportable conditions to link to clinical condition.
- *Lab test names* (described as test names and often test methods)
    - Coded values: LOINC®
    - Requirement: Support default value sets for lab test names, and allow jurisdictions to update these to meet jurisdiction-specific needs.
- *Lab test results* (specifically for results that are organisms or positive or negative)
    - Coded values: SNOMED-CT® for organisms
    - Coded values: SNOMED-CT® or HL7/PHIN VADS codes for positive/negative value sets

    - Requirement: Support default value sets for lab test results, and allow jurisdictions to update these to meet jurisdiction-specific needs.
- *Clinical observations*
    - Coded values: LOINC®
    - Requirement: Align with the new agreement between LOINC® and SNOMED®(11)
- *Clinical values/findings*
    - Coded values: SNOMED-CT® concepts for nominal and ordinal values
    - Requirement: Support default value sets for clinical findings, and allow jurisdictions to update these to meet jurisdiction-specific needs.
- *Jurisdiction context* (Name of jurisdiction and designation of geographic coverage)
    - Coded values: Federal Information Processing Standard Code (FIPS)
    - Requirement: Flow of reporting within jurisdictions must be represented to assist reporters in identifying to whom a report should be sent, for example, if it should be sent to a local health department, the reporter, must be able to determine which local health department and if it is based on the residence of the patient, the site of care delivery, or the location of the servicing laboratory.

Define User Stories and identify required data resource linkages

The workgroup reviewed user stories provided by the following stakeholders groups: epidemiologist working at a state or local health department, CDC epidemiologist, knowledge curator/terminologist, reporter, researcher, EHR vendor, laboratorian, and public health official. We grouped user stories according to the area of RCKMS that may be affected by the user story. Each set of stories includes a variety of stakeholders but similar data structure needs.

1. *User stories addressing relationships between reportable events by jurisdiction:* Story example: "I am the epidemiologist for the communicable diseases branch of my health department and I would like to see the reporting specifications for all conditions in our neighboring jurisdictions to compare against ours. In order to compare the criteria for a given reportable topic, there needs to be a way to link similar reportable events with different names or different criteria for the topic." Resource example: Show the criteria for reporting pertussis-related events from a lab or clinical setting for the following spatial contexts: Utah and Colorado. The system would need to know that pertussis and whooping cough were the same.

2. *User stories that require understanding about the relationship between semantic changes in reportable events.* Story example: "I am an epidemiologist defining a new or updating a reportable event and need to decide which subset of a condition should be made reportable. To improve consistency across jurisdictions, I want to search through the RCKMS to see related conditions from other jurisdictions and be able to view hierarchical relationships across related conditions." Resource example: In Utah, the condition 'Hantavirus infection and pulmonary syndrome' was retired and replaced by 'Hantavirus pulmonary syndrome'. In Colorado however, the change has yet to be made. What is the relationship between the two terms and the nationally notifiable condition used for national surveillance?

3. *User stories related to linking national surveillance to reportable events.* Story example: "I am the CDC epidemiologist with the National Notifiable Disease Surveillance System (NNDSS) and I need to know if states are collecting information, in other words does the state include relevant reportable events in their jurisdiction to assert that a given state is reporting Nationally Notifiable Conditions (NNCs) for their jurisdiction. Currently, this knowledge is manually derived from CSTE's State Reportable Condition Assessment (SRCA), which is retrospective and difficult to interpret." Resource example: Each year, CDC's NNDSS needs to know if each nationally notifiable condition is or is not reportable in each jurisdiction. This requires knowledge of each reportable condition in each jurisdiction and to understand whether or not it should map to a specific nationally notifiable condition for the surveillance year.

4. *User story that combines semantic changes over time and national surveillance.* Story example: I am a researcher reviewing notifiable condition reports for Shiga toxin-producing Escherichia coli over the last 10 years. I want to take into account changes in naming and classification at the national level as well as differences in how jurisdictions report the disease so my data is inclusive of all the reports that are applicable. Resource example: Three notifiable conditions (*Enterohemorrhagic Escherichia coli (EHEC) shiga toxin+ (serogroup non-O157), Enterohemorrhagic Escherichia coli (EHEC) O157:H7, and Enterohemorrhagic Escherichia coli (EHEC) shiga toxin+ (not serogrouped))* were retired in 2006 and replaced by the supertype *Shiga toxin-producing Escherichia coli (STEC)*.

5. *User stories related to criteria and mappings to code systems.* Story example: "I am a terminologist and I need to select the LOINC® codes that meet the epidemiologist's description of criteria using the organism, method and specimen source. How do I find all the relevant codes, and how do I reselect the codes as new versions of LOINC® are released." Resource example: What lab test codes should be included in the value sets corresponding to the selection logic for tuberculosis where the epidemiologist has specified a target organism, laboratory method and specimen types to be used in the logic?

6. *User story that extends #5 and combines with earlier user stories.* Story example: "I am a terminologist, and a reportable condition is being updated into two reportable conditions. I need a report to show all vocabulary that was referenced by the condition so I can determine how the references may need to be updated based on the split (or combination, or reclassification)." Resource example: Ehrlichiosis, human monocytic (HME) is being replaced by two new events: *Erlichia ewingii* and *Ehrlichia chaffeensis*.

The workgroup then reviewed an existing concept map previously created by one of the authors (CJS) that shows many of the concepts represented in reporting requirements (Figure 1). The concepts were extracted from the websites and PDF's described above, and were organized to be illustrative. The major concepts of interest are shaded. The concept map was useful for illustrating subdomains of content and some of the linkages required between concepts. The workgroup articulated several relationships between concepts, some of which are shown in the additional blue boxes (Figure 1).

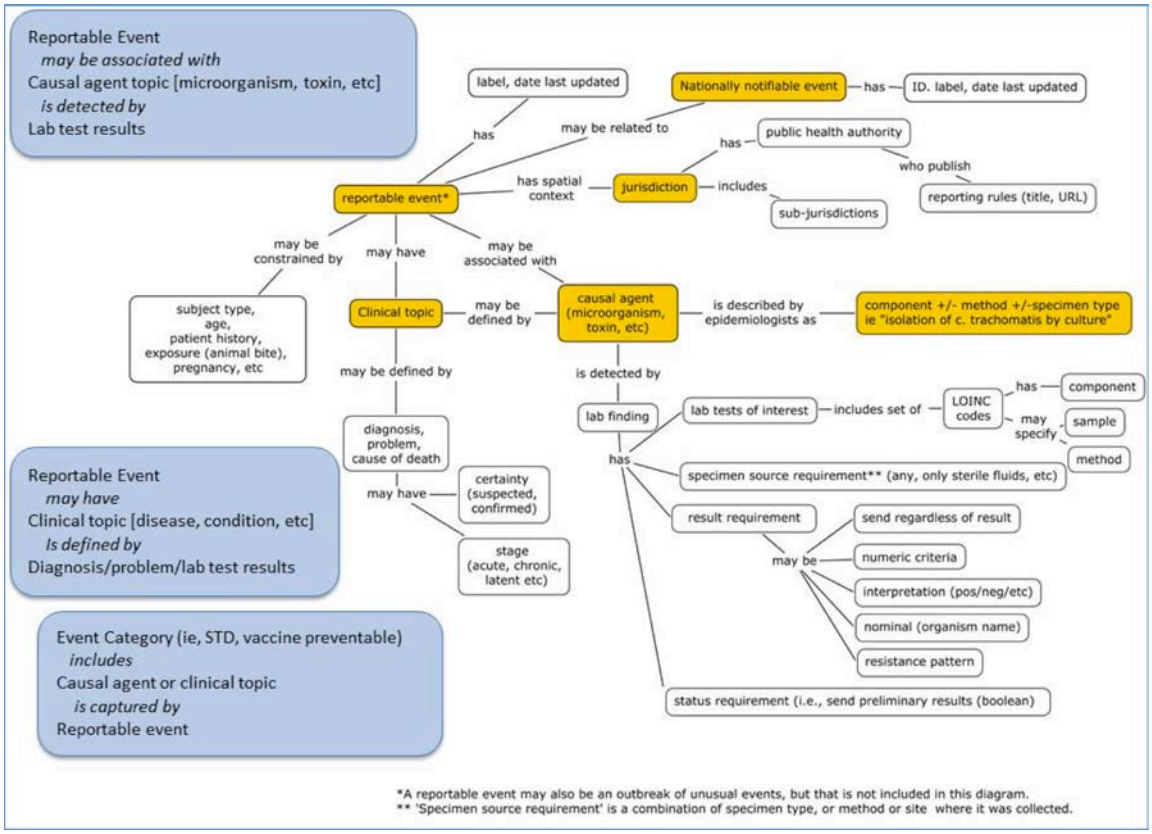

Figure 1. Map of selected concepts needed to represent reporting requirements and identify candidate areas for use of ontology to manage RCKMS knowledge (Key concepts shaded. Newly-identified relationships in boxes).

There are existing resources such as SNOMED-CT that link diseases and causative agents, but most of the linkages required for clinical and laboratory reporters to know 'what", "when", "where" and "how" to report to jurisdictional public health authorities do not exist in computable format sufficient to meet the user stories. For example, there are no existing resources to support queries based on a user's need to see reportable events related to a diagnosis ("show me all the influenza reportable events, such as the criteria for pediatric deaths or influenza hospitalizations"), or jurisdiction ("show me what is required to be reported in New York City and New Jersey"). In addition, while a

Reportable Condition Mapping Table was published in 2011 that lists LOINC® and SNOMED-CT concepts for Electronic Laboratory Reporting, the mappings were created through a manual, labor intensive process that requires manual updates as source data is updated, and the Mapping Table does not represent state reporting requirements[12].

Assess candidate knowledge domains

Using the criteria defined in the methods, the workgroup evaluated three subdomains of information within RCKMS. Ontologies were considered as tools to manage the following knowledge: reportable events, jurisdiction relationships, and reporting logic. The ontologies would be used for both standardizing the authoring of content and for querying RCKMS data. The findings are summarized in Table 2. The assessment illustrates a strong need for the use of ontologies to manage information about reporting logic and reportable events. There is not strong evidence for a need to manage jurisdiction information in an ontology. The hierarchical structure of jurisdictional information can be managed using mapping tables.

Table 2. Evaluation of candidate domain areas for ontology development based on criteria for ontology use.

Sub-domains of RCKMS knowledge		
Reportable event	**Jurisdiction**	**Reporting logic (particularly laboratory-based logic)**
1. How complex are the relationships in the data?		
Complex relationships between reportable events, conditions and reporting criteria. Also, need to track semantic changes over time.	Simple relationships	Complex relationships between selection criteria and value sets.
1(b). Is there an inheritance of qualities between the data?		
Within a single jurisdiction, events tend to be mutually exclusive. When attempting to aggregate across jurisdictions or over time, inheritance becomes an issue	Cities/Counties inherit state-based rules and sometimes include additional reporting rules of their own.	Lab tests have inherent hierarchical structure.
2. Is there a logical structure to the data?		
Yes, events are about conditions, and have defining criteria. Events evolve over time and have relations to previous events. Jurisdictional events can be related to national events.	Yes. Spatial structure and reporting flow structure.	Yes
3. Are users interested in questions that can more easily be answered if data relationships are ontology-based?		
Yes - see user stories 1,2,3,4,6.	No user story described a need.	Yes - see user story 5.
4. Does the data change over time?		
Yes, jurisdictional and national reportable events change yearly (or more frequently).	Stable	Yes, updates to reporting criteria occur yearly or more frequently. LOINC® files are updated every 6 months
5. Are there multiple user groups, and need for a common understanding?		
Yes. Authoring and reporting users. Also, national and jurisdictional reportable event developers.	Yes. Authoring and reporting users.	Yes. Authoring and reporting users. Multiple other uses for value set creation.
6. Is maintenance of the data a manual burden and creating a bottle neck?		
Yes, Large manual burden. Currently, the State Reportable Condition Assessment[13] provides some capacity, but only retroactively with several year delay. No logical relationships used to manage tracking of event development, or mapping between national and jurisdictional events	No. Small burden	Yes. Large manual burden. Updates to selection criteria or underlying data sources (i.e., LOINC®) result in large manual undertaking to produce new value sets.
7. Does reasoning need to be performed to utilize the knowledge?		
Yes, traversal of terms in a well-developed ontology could aid in surveillance questions.	Reasoning can be performed over existing spatial relations	Yes, tests can be described logically and reasoned into

Reasoning may be valuable.	(e.g.,"What events should be reported for X city in Y county in Z state?")	hierarchical structure for management of value sets.

Recommendations and Discussion

The workgroup evaluated the knowledge needed and the resources currently available to effectively address the user stories and necessary linkages between resources. Two areas of the reportable condition domain were agreed upon by the workgroup as candidates for ontology development. The undertaking of ontology development for a large project like RCKMS is not to be taken lightly and the workgroup made recommendations regarding implementation and ontology management.

Recommendations for domains to be managed using ontologies

The following areas of RCKMS knowledge were recommended to be managed using ontologies.

- *Reportable Events:* An ontology of reportable events would allow RCKMS to meet the surveillance and querying requirements. The concepts to be managed by this ontology are the events, the relationships between active and retired events, the relationship between national and state-defined events and the criteria associated with given events. A reportable event ontology is a complex undertaking that involves management of concepts from the national and jurisdictional level. This is of high priority. The surveillance use cases require RCKMS to be able to track conditions over time, but the events that capture the conditions change. The querying use cases need to be able to evaluate what is currently reported, with what was previously reported, and to do so across changes at the state/local jurisdiction level, as well as at the national level. Therefore, the ontology would need to relate the reportable events to their criteria, and how they relate to each other. A key component of this reportable event ontology will be defining the relationships that exist between terms such as *replaced by*, that allow us to understand the evolution of the usage of a condition.
- *Reporting Logic:* An ontology to manage reporting logic, particularly to select value sets using LOINC®, would provide consistency when authoring RCKMS content. The base content for this development may come from information already gathered by CSTE, including Position Statements and their associated technical implementation guides, and information gathered from the State Reportable Condition Assessment (SRCA). The technical implementation guides were a onetime effort and have not been updated since 2008 to reflect updates that may have occurred to CSTE Position Statements for Notifiable Conditions. After the initial population of terms, there will be a phase of jurisdictional curation. The content will need periodic updating as the referenced datasets (e.g., LOINC® are updated, and reporting logic sets are updated by each jurisdiction. These updates will be jurisdiction specific. Previous work[14-16] successfully demonstrated the use of ontologies to hierarchically query the LOINC® database, and highlighted issues that must be resolved: 1. LOINC® cannot effectively be queried hierarchically in its present form. 2. The component axis of LOINC® is not suited for epidemiological queries. 3. There are data restriction issues relating to public access of the hierarchical structure in LOINC®

Recommendations for ontology management

- *Allocate adequate resources to support the stages of ontology development***.** The first stage; exploration of necessity, has been completed by this workgroup. The use of ontologies is justified for this project to unify the semantics used to describe similar concepts between different groups, to aid data integration, to allow logical inference over data and to manage large, unwieldy datasets. Ontology development needs a team approach: It is a specialist task and requires both domain knowledge and understanding of ontology technology and the existing data infrastructure and the semantics of the data. Creation of ontologies will be undertaken by knowledge curators with the assistance of technologists. The knowledge curators will be domain experts in the field of public health, who have some training in the ontology development. The technologists will be familiar with ontology development and application, and be trained in the use of an ontology management system. They will also be familiar with databases and the existing data. They will utilize input from a variety of sources to drive development (e.g., spreadsheets, textual information). To ensure that the ontologies accurately represent the semantics of the domain, a process of oversight and curation will be utilized. Testing and deployment tasks will be undertaken by the technologists and IT team. Maintenance will be vital to continue to support the community after development and deployment. This will involve updates coming from external data sources such as LOINC® and updates from public health data (national and jurisdictional). Maintenance should be less labor intensive, but longer running than the initial development.

- *Use a hybrid approach to ontology development for the RCKMS.* There are three high level strategies for ontology development: top-down, bottom-up and hybrid; each approach has pros and cons and is suited to a different entry point in the process of elucidating and codifying ontologies. *Top-down* ontology development starts with defining and then extending top level core concepts, from very general terms, to very specific. This approach forces the developer to identify the key foundational concepts and their relationships from the beginning, and often leads to a comprehensive ontological model of the data. Existing foundational ontologies may be used (for example, Basic Formal Ontology, BFO[17]) to form the basis of the domain ontology. This method is good for consensus building among multiple groups. *Bottom-up* approaches to ontology building use pre-existing data sources as the starting point of development and take the reverse approach of specific to general term development. This is well suited for data integration projects, but often produces an incomplete model of the domain. The *hybrid approach* takes a pragmatic approach to the modeling problem – in that it uses both of the previous approaches to come to a consensus view. It is suitable for projects where there is need to harmonize the semantics used by the community and help provide conversion to heterogeneous datasets. The problems being addressed by RCKMS are wide, and there are elements that are best suited to both top-down and bottom-up development. There are many existing resources used in this project, such as each jurisdiction's reportable event criteria, that may best be handled with a bottom up approach. It would however, be of great benefit to this community to develop a comprehensive domain ontology that is rooted by a foundational ontology. There is also evidence that suggests that using a foundational ontology does not slow development and improves interoperability and quality [18].

  The ontologies developed for this project have the potential to provide a valuable resource to other investigators in the wider biomedical community. To enable and promote reuse, it is recommended that an upper ontology be used to place the terms developed into a wider context. An upper ontology such as BFO provides very high level terms upon which more specific ontologies can be developed. For example, there is a division between continuants and occurants, and between dependent and independent continuants. This upper level specification of the world forces the specific ontology developer to frame the new terms with the organizing principles in mind. The agreement imposed by the upper level ontology promotes reuse and interoperability of ontology terms. Providing consistency in the definitions of relationships used in the ontologies enables inference and reasoning over the ontologies. The Open Biomedical Ontology group's Relations Ontology [19] provides a starting place to obtain and then extend relations for the ontologies built for RCKMS. Another option to promote the reuse of the ontologies developed here would be to host them on the National Center for Biomedical Ontology's BioPortal website [20].

Recommendations for ontology development

The workgroup had specific recommendations regarding the management of ontology development: It is recommended that the ontology development be transparent, open source and versioned, preferably with a versioning system such as SVN and hosted via a collaborative site such as Google Code.

The project should provide a system to capture change requests to the ontologies. It is envisioned that there will be two mechanisms for development and change to the ontologies. The first is batch sets of changes relating to the updates of other datasets (new terms in LOINC®, yearly updates to selection logic by a jurisdiction). The second mechanism for change is via a developer working in a given knowledge area discovering the need for a new concept. These term requests should be tracked and managed in a way that is transparent and traceable. Many ontology projects use a term request tracker to document this process.

Where applicable, existing ontologies and knowledge representations should be used. The necessary terms can be imported into the RCKMS ontologies and strategies need to be in place for updates of existing terms. Some tools such as Ontofox [21] exist for Web Ontology Language (OWL) ontologies that allow this process to be managed.

The knowledge captured by the RCKMS project has the potential of being vast and complex. Large ontologies are not uncommon in the biomedical domain. Bada et al. evaluated the Gene Ontology for elements of success and concluded that **clear goals**, **simple intuitive structure**, **early use**, **community engagement**, and **continuous evolution** were the key factors [22]. The following questions have been addressed to find solutions that will work for the particular requirements of RCKMS:

- *Clear Goals***:** One large all-encompassing ontology or several small ontologies? A practical solution to the knowledge management issues presented to this workgroup has led to the delineation of two areas for focused ontology development within the scope of RCKMS. They include:

a) An ontology about reportable events
b) An ontology to query LOINC® and develop value sets for selection logic

These two areas are sufficiently distinct from each other to warrant separate ontologies, developed by expert content leaders.

- *Intuitive structure: Separate ontology and data.* There are several examples in biomedicine of large ontology projects where the data is captured separately from the ontology; the Gene Ontology Consortium [23] being a good example. The ontology development is managed independently from the annotation of the ontology terms to the data. In this way, a few developers maintain control of the content of the ontology while annotators manage the data. This is a good model for the RCKMS where a small number of terminologists or content managers will be responsible for the terminology, but a larger group of interested parties will use the ontology – for example with the authoring use cases. This proposed work must capture the knowledge necessary to automate the processing of public health data. This knowledge falls into several domain areas. While it is possible to incorporate ontologies into systems, and reason over and query them on the fly, it is also equally feasible to manage the knowledge separately in an ontology, and export the reasoned statements from the ontology to the system. Separation of the ontology from the system has the benefit of easier maintenance, less software complexity, quicker response time when queried, and would offer a quicker path to operationalize within the current architecture.
- *Community engagement.* Key stakeholders (in the downstream use of the knowledge) must be involved in the development of the ontologies.
- *Early use.* RCKMS should provide ontologies and annotations to public health community for use as early as possible. The ontologies and systems developed should be promoted and disseminated to the wider community, while providing a forum for feedback. There must be a visible, accessible website for RCKMS documentation, including links to the ontology resources and documentation to allow community use and feedback. The ontology should be released in formats digestible by current tools.

Conclusion

Currently the management of knowledge surrounding reportable conditions is a manual task, for both those providing the rules and those interpreting the rules. The tasks of authoring are manually driven, as base content for conditions is not maintained electronically. Surveillance of conditions over multiple jurisdictions is an onerous manual task, as there is no connection between the national reportable event, and what is reported locally. Reporting has a large manual component as the jurisdictional rules must be interpreted and implemented locally – requiring each reporter, for example to decide which positive LOINC® tests to report for a given condition. Given that the content of external resources and reporting rules change periodically, the amount of manual mapping and updates is considerable. The RCKMS aims to provide efficient, automated solutions to these problems.

Complex information is required to support RCKMS and provide computable, viewable and usable information for reporters to know what, where, when and how to report to public health. Ontologies have been applied successfully to manage the knowledge of other large domains within the biomedical informatics community, and the workgroup concluded would be an appropriate tool for to manage reportable condition knowledge. Ontologies are indicated for two specific domains of content: selection logic criteria and reportable events. The undertaking of ontology development for a large project like RCKMS is not to be taken lightly, and ontology development should be transparent, open source, and versioned using strategies that leverage existing ontologies and allow reuse of the knowledge developed for the RCKMS effort.

Acknowledgements

The RCKMS project is funded by the CDC, Office of Public Health Scientific Services (OPHSS). We would like to thank members of the RCKMS Knowledge Representation Working group for voluntary participation in weekly discussion during 2013. The Number Needed to Remind: a Measure for Assessing CDS Effectiveness

Jonathan Einbinder MD, MPH[1,2,3], Esteban Hebel, MD, MMSc[1,4], Adam Wright, PhD[1,2,3], Morgan Panzenhagen[3], RN, Blackford Middleton MD, MPH, MSc[1,2,3]

Abstract

Background: Clinical decision support (CDS) is associated with improvement in quality and efficiency in healthcare delivery. The appropriate way to evaluate its effectiveness remains uncertain.

Methods: We analyzed data from our electronic health record (EHR) measuring the display frequency of eight reminders for Coronary Artery disease and Type 2 Diabetes and their associated performance according to a predefined methodology. We propose two key performance indicators to measure their impact on a target population: the reminder performance (RP), and the number needed to remind (NNR), to evaluate the impact that Clinical decision support reminders have on the adherence to guideline derived CDS interventions on the entire patient population, and individual providers receiving the interventions.

Results: Data were available for 116,027 patients and a total of 1,982,735 reminders were displayed to a subset of 65,516 patients during the study period from January 1 to December 31, 2010. The evaluation framework assessed provider acknowledgement of the CDS intervention, and the presence of the expected performance event while accounting for patients' exposure to the CDS reminders. The total RP was 2.7% while the average NNR was 3.1 for all the reminders under study.

Conclusions: The proposed framework to asses of CDS performance provides a novel approach to improve the design and evaluation of CDS interventions. The application of this methodology represents an indicator to understand the impact of CDS interventions and subsequent patient outcomes. Further research is required to evaluate the impact of these systems on the quality of care.

1 Introduction

Meaningful use of health information technology is viewed as essential for effecting change in healthcare delivery.[1] Effective use of clinical decision support (CDS) is one of the components that help physicians and other health care providers treat patients according to evidence-based guidelines for care.[2–5]

Reminders are one common type of CDS usually triggered by patient data or information entered by the user. They are intended to prompt the healthcare provider about the appropriate interventions or to avoid certain actions to improve the patient individual care.[6] In the literature, reminders have been found to improve some preventive practices and compliance with clinical guidelines in regard to medication selection and diagnostic testing.[7]

However, some research has found that reminders achieve modest or no improvement in care.[6,8–10] In addition, current research has suggested that an overabundance of reminders may counteract their effectiveness and lead to user dissatisfaction.[11,12] Our approach focuses on the expected actions in preventive care that can be attributable to the reminder being displayed and acted upon from a population perspective. Existing evidence on the topic is conflicting and understudied.[13]

In research conducted by the CDS Consortium[14,15], we developed a CDS Dashboard to inform end users as to their use of decision support and compliance with CDS recommendations, and implemented it at the Partners Healthcare System. The CDS Dashboard also provides feedback to the research team about CDS performance characteristics, including usage and compliance rates, user performance for key metrics, compared to other users or reference benchmarks.

The purpose of this paper is to provide a better understanding of population based CDS performance measurement, to identify best practices for designing and implementing CDS, and to introduce two new quality measures, titled Reminder Performance (RP) and the Number Needed to Remind (NNR) for evaluating the effectiveness of clinical reminders in the context of the CDS Dashboards.

2 Methods

2.1 Study Setting

The CDS Consortium was funded by the Agency for Healthcare Research and Quality (AHRQ) to address the challenge of documenting, generalizing, and translating the CDS adoption experience at advanced sites to broader community settings.[14] The Consortium was created when investigators from Partners HealthCare (PHS) Information Systems (IS) formed an alliance with several other institutions intimately involved in creating and providing CDS tools and services in EHR's. Furthermore, a CDS rules service has been implemented to enable sharing of CDS on an advanced rules engine platform among consortium members.[16]

Within the AHRQ CDSC project, eight reminders were studied (Table 1) from January 1, 2010 to December 31, 2010. All were synchronous passive reminders triggered by opening the patients' electronic chart. For each reminder, we obtained data from the Longitudinal Medical Record including: patients who were eligible for the measure (the denominator), patients that had already or subsequently received the recommended action (the numerator), the reminders

displayed – when and to whom- as well as the provider acknowledgement to the reminder, and a coded response. This data was loaded into the Partners Quality Data Warehouse (QDW) and dashboards were constructed in Report Central[17] using Crystal Reports™.

Table 1 Reminders

Condition	Reminder	Measure	Reminder
CAD	CAD and no Aspirin	Patient has CAD and aspirin is on the medication list	Patient has CAD-equivalent on problem list and aspirin is not on the medication list. Recommend aspirin.
Diabetes	Diabetic overdue for HbA1c	Diabetes, HbA1c completed in the past 6 months	Patient with Diabetes Mellitus overdue for HbA1C
Diabetes	Diabetic almost due for HbA1C	Diabetes, HbA1c completed in the past 6 months	Patient with DM is due for HbA1C by <mm/dd/yyyy>
Diabetes	Diabetes overdue for Microalbumin/creatinine ratio	Diabetes, Microalbumin completed in the past year	Patient with diabetes overdue for urine Microalbumin/creatinine ratio
Diabetes	Diabetes almost due for Microalbumin/creatinine ratio	Diabetes, Microalbumin completed in the past year	Patient with diabetes almost due for urine Microalbumin/creatinine ratio by <mm/dd/yyyy>
Diabetes	Diabetic overdue for ophthalmology exam	Diabetes, Ophthalmology exam completed in past year	Patient with diabetes mellitus overdue for ophthalmology exam
Diabetes	Diabetic almost due for ophthalmology exam	Diabetes, Ophthalmology exam completed in past year	Patient with diabetes mellitus almost due for ophthalmology exam
Diabetes with Renal Disease	Diabetes Mellitus and Microalbumin/creatinine ratio >30	Diabetes, Microalbumin/creatinine ratio>30, and on ACE-inhibitor, ARB	Patient with diabetes mellitus, Microalbumin/creatinine ratio >30 and not on ACE-inhibitor, ARB. Recommend ACE-inhibitor or ARB

Detailed list of CDS reminders by condition.

2.2 Dashboard Design and Development

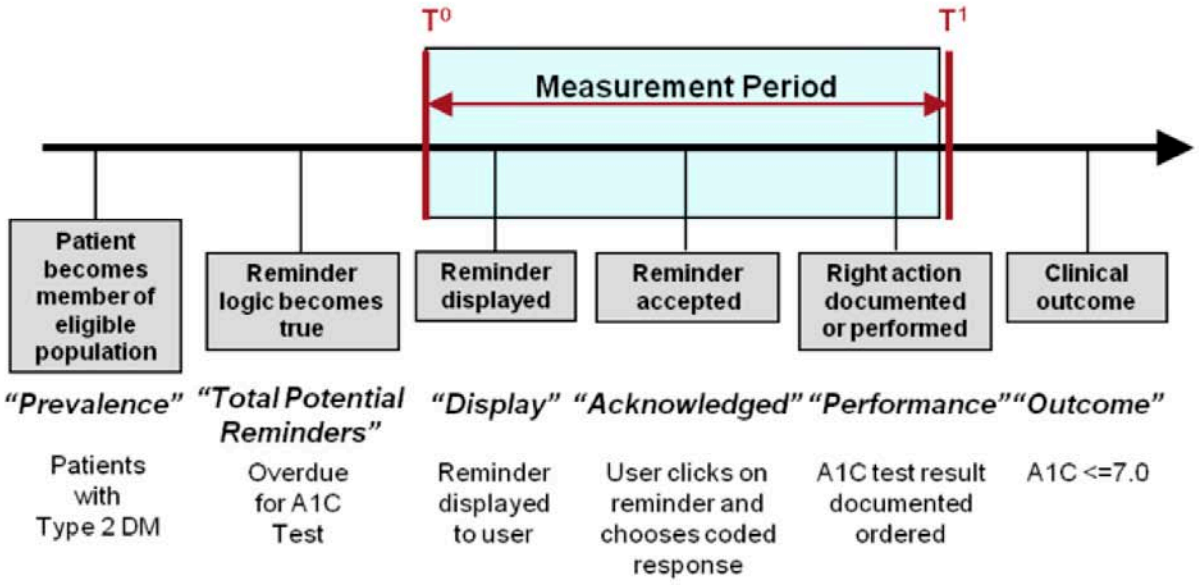
Two separate dashboards were built to target clinicians and CDS implementers (knowledge engineers). To accomplish this, the thoughts and requests of each type of user were considered and incorporated in the design process. Iterative designs were prototyped incorporating feedback from the CDS Dashboard Team, which was comprised of senior medical informaticians, senior knowledge engineers, and the principal investigator. It was determined that the clinician dashboard would present information regarding clinical performance for patients determined by the reminder logic (Table 2), which would then be organized by condition and compared to their peers. In comparison, the designer view was created to address reminder performance.

Table 2 CDS Reminder Performance logic per measure

Measure	Performance measurement
Patient has CAD and Aspirin is on the medication list	Patient has CAD and aspirin is on the medication list before the period start date and there is no stop date on the med entry that is before the period end date.
Diabetes, HbA1c completed in the past 6 months	Patient has an HbA1C entry < than the period end date and >6 months before the period start date.
Diabetes, Microalbumin completed in the past year	Patient has a MALCR entry entered < than period end date and >than 12 months before the period start date.
Diabetes, Ophthalmology exam completed in past year	Patient has an Ophthalmologic exam entry entered < than the period end date and > than 12 months before the period start date.
Diabetes, microalbumin/creatinine ratio>30, and on ACEI/ARB	Patient has an ACEI/ARB on their medication list before the period start date and there is no stop date on the medication entry that is before the period start date.

The designer view displays the level of acknowledgement of reminders, reminder performance by patient group, and specific data related to reminder effectiveness, including: reminder prevalence, reminder presentation, reminder acknowledgement defined as “the formal declaration of a reminder being received and acted upon” (Figure 1), CDS performance, and the NNR. Within the QDW, there are two ways of looking at each reminder – the first looks at the number of displays, defining a display event as the reminder being shown on the screen to an LMR user for a particular patient, where display events are counted by provider-patient-month. The second approach defines a reminder event at the patient level for the entire study period, i.e. the reminder being shown on a screen to any LMR user for a particular patient, treating each patient-year as one display event, while considering the patient compliant when the performance action was recorded within the following month from the reminder being displayed.

Figure 1 Timeline detailing the reminder lifecycle.



2.3 Proposed Measurement Framework

A measurement framework was developed to consider the lifecycle of an ambulatory EHR reminder (Figure 1). This lifecycle suggests the kind of events, actions and outcomes that can be used to define rates and measures to assess CDS effectiveness. Each stage of the lifecycle is associated with a particular measure: prevalence, logic, display, acknowledged, performance, or outcome. For each reminder, we defined the numerator and denominator for clinical performance. This refers to whether or not a patient who is part of the eligible population received the recommended action, independent of whether a reminder was displayed or not. Ultimately, the key to reminder effectiveness is the contribution the reminder makes to overall

clinical performance, i.e. when the reminder is displayed, how often the recommended action is subsequently taken. This can be expressed in a measure we call "CDS Reminder Performance" (RP) (Table 3).

2.4 Number Needed to Remind (NNR)

In 1988, Laupacis *et al.* proposed a measure of clinical benefit intended to capture value of certain clinical interventions – the number needed to treat (NNT)[18–20], calculating the inverse of the absolute risk reduction. Similarly, the Number Needed to Harm (NNH) reflects the number of patients that have to be exposed in order to harm one patient that otherwise would not have been harmed. We applied the same approach in an analogous fashion to reminders and proposed a new measure of reminder effectiveness called the "Number Needed to Remind" (NNR). Consequent with the NNT, the ideal NNR is 1, reflecting that every reminded patient will benefit from the reminder being displayed to one or more of their care providers.

The NNR corresponds to the number of patients reached by the reminder to result in one recommended action being taken or:

$$NNR_t = \frac{\text{total patients with reminders displayed over time t}}{\text{total patients with reminders and perfomance over time t}}$$

The denominator represents the number of patients to whom a reminder was followed by the appropriate performance event within 30 days of the end of the reporting period. The numerator corresponds to the cumulative count of patients with reminders displayed in each measurement period.

We used the performance data, including the NNR, to assess the effectiveness of each reminder and were able to gain some potential insights related to how well they function in the clinical setting. The logic to calculate the performance per each of the measures under study is explained in detail in table 2.

3 Results

During the study period, 1,982,735 reminders were triggered for the rules described in Table 1, being displayed to 12,327different providers. From the cohort of 116,027 patients included in the study, 65,516 of them were exposed to the one or more of selected reminders during the study period.

As a validation through example, we evaluated one reminder for diabetic patients who were overdue for their HbA1c after 6 months. During the study period the reminder was displayed 355,361 times (Table 3) to a total of 40,745 different patients (Table 4). Out of those patients, 16,549 (40.6%) of them had a performance event, defined as an HbA1c present in laboratory tests results database (Table 2) during the 30 days following the reminder being displayed. The RP for this rule would be the ratio of patients with performance over the total number of reminders displayed; for this particular example the RP for the Overdue HbA1c would equal 4.7 patients in performance per 100 reminders displayed. This indicator reflects the effectiveness of each reminder displayed on the expected performance. In contrast, when we calculate the inverse

of the patient performance we obtain a NNR of 2.5, reflecting the number of patients receiving the reminders in order to get one patient to comply with the defined performance measure (Figure 2).

Table 3, shows the number of reminded patients for whom the relevant performance action was found, and the total number of patients displayed with a reminder. The RP is the percentage of patients with reminder and performance over the total number of reminders displayed. Table 4 shows the reminders with performance for displayed patient reminders per month: NNR (the Number of patients needed to remind).

Table 3 CDS Reminder Performance for all patients' total reminders per month

Rule Name	***Reminder with Performance***	***Total Reminders***	***CDS Reminder Performance (%)***
CAD and no Aspirin on medication list	2,589	131,721	***2.0%***
Diabetes Mellitus and microalbumin/creatinine ratio >30 and no ACEI/ARB on medication list	1,668	57,678	***2.9%***
Diabetes overdue for Microalbumin/creatinine ratio	2,927	215,626	***1.4%***
Diabetes almost due for Microalbumin/creatinine ratio	11,864	82,385	***14.4%***
Diabetic overdue for HbA1c	16,549	355,361	***4.7%***
Diabetic almost due for HbA1c	13,751	70,024	***19.6%***
Diabetic overdue for ophthalmology exam	2,863	1,048,478	***0.3%***
Diabetic almost due for ophthalmology exam	1,947	21,462	***9.1%***
Total	***54,15***	***1,982,875***	***2.7%***

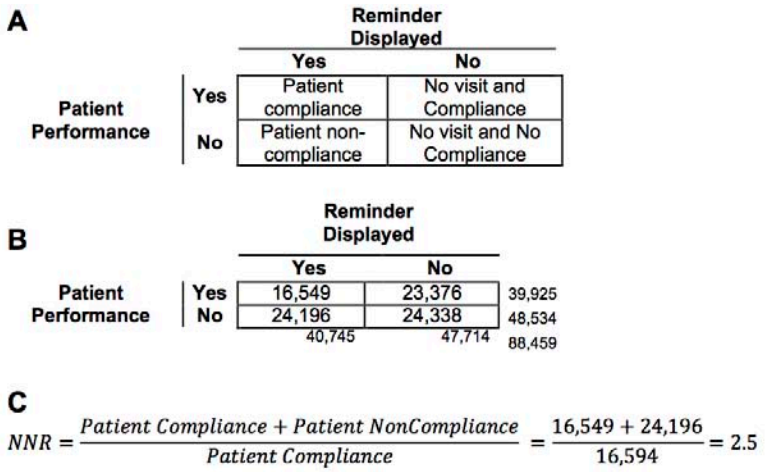
Table 4 Reminders with Performance for displayed patient reminders per month: NNR (the Number of patients needed to remind).

Rule	***Reminder with Performance***	***Patients with Reminders Displayed***	***Number Needed To Remind(NNR***
CAD and no Aspirin on medication list	2,589	*7,051*	2.7
Diabetes Mellitus and microalbumin/creatinine ratio >30 and no ACEI/ARB on medication list	1,668	2,949	1.8
Diabetes overdue for Microalbumin/creatinine ratio	2,927	*21,466*	7.3
Diabetes almost due for Microalbumin/creatinine ratio	11,864	*15,227*	1.3
Diabetic overdue for HbA1c	16,549	*40,745*	2.5
Diabetic almost due for HbA1c	13,751	*18,403*	1.3
Diabetic overdue for ophthalmology exam	2,863	*57,889*	20.2
Diabetic almost due for ophthalmology exam	1,947	*5,020*	2.6
Total	***54,158***	***168,750***	***3,11***

The evaluation of the CDS reminder performance by differentiating four scenarios in decision support performance, as explained in Figure 2, can distinguish patients in compliance with the performance measure from non compliant patients, while accounting for those patients affected by the reminder. From all eligible patients, considered the prevalence for the evaluated condition, only a fraction has a healthcare provider visit during a specified time frame, thus since the patient had no recent performance event (e.g. patient is overdue for HbA1c) and not having a reminder being displayed, produced the effect of patients without reminders and no performance.

The opposite scenario occurs when a patient is in compliance although no reminder was triggered. These patients could be in performance most commonly because of a proactive care team.

Figure 2 CDS performance evaluation framework for passive reminders for HbA1c to be completed every six months to the entire population of diabetic patients found in the Partners Healthcare System. (A) Distribution of all the active diabetic patients depending if they have received a reminder and whether they are in compliance with the performance measure. (B) HbA1c compliance among diabetic patients in Partners population. (C) Computation of the Number Needed to Remind based on CDS performance framework.



4 Discussion

Using routinely collected data in our EHR, we were able to examine the effectiveness of ambulatory care reminders for diabetes mellitus and coronary artery disease. Specifically, we measured the number of eligible patients that were receiving recommended care (clinical performance) and the effectiveness of the reminders displayed toward the healthcare providers (reminder performance). By identifying the patients with reminders displayed and those that received a suggested action, we calculated the Number Needed to Remind, i.e. the number of patients required to be reached by CDS reminders that are associated with one additional patient receiving recommended care. This measure, the NNR, may be useful for monitoring and differentiating the relative effectiveness of CDS rules.

The NNR measure clarifies the difference between the effectiveness of the reminder (RP, Reminder Performance) as an isolated entity from the Reminder effect on the patient level, and furthermore highlights the subtle differences in the reminder logic or documentation requirements that are associated with dissimilar performance. For example, looking at the almost due and overdue reminders for eye exam and HbA1c (Table 4), the “Overdue” reminder had a notably higher NNR than the “Almost Due” reminder. We speculate that this may be attributable to a number of factors that create a bias in the patient population that receives each reminder.

This unintended patient selection bias could be explained by the fact that to trigger an “Almost Due” reminder, a prior performance event needs to be present in the database and, more importantly, needs to be properly documented in a previous episode of care including a computable time stamp. Further, the “Almost Due” temporal logic allows for a higher degree of tolerance meaning that the reminder may fire in advance of a strict due date. In this case, the reminder will work better in those sites where providers document at the point of care and use the features in the EHR appropriately.

Advanced CDS may fail to achieve ideal care if it relies on incomplete or unstructured information that is considered difficult to acquire and maintain for the appropriate display of reminders and other forms of decision support. Here we can differentiate two scenarios. First, a lack of structured information will impede the display of the reminder or it will be displayed in a wrong clinical scenario. The second will occur when the performance event is not documented appropriately and the reminder will not stop triggering. The Ophthalmologic exam to diabetic patients (Table 1) is usually not documented as discrete data in the LMR – it is often free text in patient notes. Consequently, despite the performance action has been taken, the reminder keeps triggering and the corresponding performance evaluation cannot be reliably measured.

To evaluate the performance of CDS knowledge artifacts and compare them cross EHR interventions would enable a comparative effectiveness analysis of reminders implemented in different EHRs, locations or implementations. To evaluate the same rule and assess whether one implementation vs. another had a better NNR, or assess the variations in the NNR across EHR systems using the same reminders, would be revealing and could allow discovery of the appropriate design patterns that EHR and CDS interventions should follow.

In a recent study, a framework to evaluate the appropriateness of clinical decision support was proposed.[21] In contrast, our study examines the analytical component of the quality of care within the institution. Our approach seeks to examine the effectiveness of the knowledge artifacts as isolated entities as well as from the patient perspective and provide the tools that would enable to elucidate the reasons behind the poor performance that clinical decision support interventions may have. We believe that both approaches are complementary since the first event to be scrutinized in the clinical performance of decision support is whether the reminder is being displayed appropriately. We broaden the scope for this study and defined that improvement efforts should be driven by clinical performance.

Evaluation of Clinical Decision Support Systems is becoming increasingly important in those institutions that have chosen to use these systems to improve quality and safety. The development of accurate performance indicators will allow the comparison among different institutions, playing a key role on standardizing care in the near future. By setting a common ground and start comparing the effects of different reminder rules we will start discovering features and functionalities that can solve the issues we confront on a daily basis.

5 Conclusion

Healthcare information technology is changing the way that we treat our patients and CDS can play an important role to improve the quality of care that we deliver. We identified different measures that might be helpful to assess the performance of CDS, and described the potential interpretation in context. More research is required to develop a comprehensive CDS assessment framework, and to further evaluate these measurements. New indicators to accurately reflect the clinical performance of a CDS reminder are required, to concentrate the improvement strategies on specific aspects throughout knowledge artifact lifecycle. This study reinforces the importance of clinical performance evaluation as a key function in the CDS lifecycle that could increase effectiveness and finally improve care.

Characterizing the Sublanguage of Online Breast Cancer Forums for Medications, Symptoms, and Emotions

Abstract

Online health communities play an increasingly prevalent role for patients and are the source of a growing body of research. A lexicon that represents the sublanguage of an online community is an important resource to enable analysis and tool development over this data source. This paper investigates a method to generate a lexicon representative of the language of members in a given community with respect to specific semantic types. We experiment with a breast cancer community and detect terms that belong to three semantic types: medications, symptoms and side effects, and emotions. We assess the ability of our automatically generated lexicons to detect new terms, and show that a data-driven approach captures the sublanguage of members in these communities, all the while increasing coverage of general-purpose terminologies. The code and the generated lexicons are made available to the research community.

Introduction

As online health communities like forums, blogs, and mailing lists become increasingly prevalent, patients are turning to these resources for information exchange and interaction with peers [1]. Patients with breast cancer, in particular, rely on cancer-specific online health communities for both informational and emotional support [2–6]. While this type of social networking has become central to the daily lives and decision-making processes of many patients, there are still many research questions open. For many research activities, capturing domain knowledge about topics discussed in a community and organizing terms and concepts discussed into lexicon and terminologies is needed for knowledge discovery and information extraction [5,7]. Designing automated tools to build these lexicons is a challenging task, however, because the language used in online health communities differs drastically from the genres traditionally considered in the field of information processing and from the sublanguages already investigated in the biomedical domain [8,9]. Health community vocabulary is characterized by abbreviations and community-specific jargon [10], and posts are authored in a style-free and unedited manner, with often informal and ungrammatical language. In addition, the content of the posts is both emotionally charged and dense with factual pieces of information, indicating that specific semantic types of information, like emotions, are more prevalent than in traditional biomedical texts.

In the biomedical domain, there are several clinical terminologies available that provide candidate keywords for lexicons, such as names of diseases, procedures, and drugs [11,12]. There exist health-consumer oriented terminologies, but their focus is on health consumers rather than patients in online communities, which have a different level of health literacy and convey at once a larger and more granular vocabulary for health terms than general health consumers [13]. More recently, researchers experimented with crowdsourcing to identify medical terms in patient-authored texts, but show that further processing and supervised learning is still needed to achieve acceptable results [14]. Finally, like for methods trained in other genres, existing terminologies, whether clinical or health consumer, do not cover the many misspellings and abbreviations typical of a given online health community and require manual updating to capture new terms introduced into the sublanguage [15,16].

Automated creation of lexicons has a long history in natural language processing. Unsupervised named entity recognition, and the use of seed terms in particular as a starting point for lexicon building, is a practical and promising method because it does not require a corpus, manually annotated with examples of terms [17]. Instead, seed terms are leveraged by looking for candidate terms with high context similarity to the seed terms. In the biomedical domain, such an approach has been used to identify disease names in medical mailing lists [15], recognize clinical and biological terms [18,19]. The approach is rooted in the Distributional Hypothesis, which states that words with similar contexts tend to have similar meanings [20]. In the biomedical domain, distributional semantics has been used for a wide range of tasks, such as matching MEDLINE abstracts to terms in an ontology [21], automatic generation of synonyms for gene and protein names [22], evaluation of language incoherence in patients with schizophrenia [23], and identifying semantically similar concepts in clinical texts [24,25], to name just a few [26–28].

In this paper, we describe an unsupervised method to generate lexicons representing the sublanguage of an online health community focusing on specific semantic types. Starting from a seed set of terms, all in the same semantic category (like medication names), it computes a typical context in which terms of that category occur. The context representative of a semantic category is then leveraged to identify new terms, which can augment the lexicon. To assess the value of our method and the generated lexicons, we ask the following research questions: (i) Can the method identify new terms to augment a seed set, and if so how accurately? (ii) How well does the method perform on generating lexicons for different semantic categories? And (iii) how stable is the method with respect to the quality of the underlying seed set?

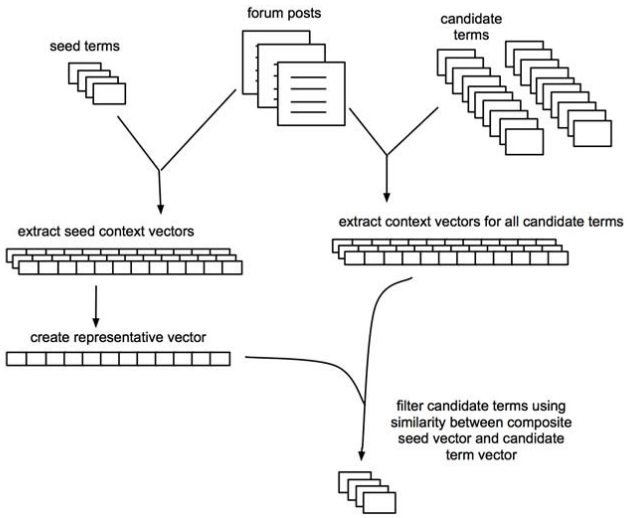

Figure 1. Overall pipeline to identify in an online health forum the terms representative of a specific semantic category.

Methods

The procedure for detecting terms in a forum that are representative of a specific semantic category is outlined in Figure 1. A seed set is gathered (either from an existing lexicon or from a small manually created one) representative of a given semantic category. Seed terms and their context, as defined from their occurrences in the online forum, are aggregated into a representative context vector, which reflect the typical context for terms in the category. As such, the representative vector acts as an implementation of the distributional hypothesis, where a word is defined by the context in which it is conveyed. To identify new terms for the semantic category, candidate terms from the forum are selected and an individual context vector is defined for each. Determining whether a candidate term belongs to a semantic category is achieved by computing the similarity between its individual context vector and the semantic category's representative vector. If a candidate term is used with words and patterns similar to the ones of the semantic category, it is likely the candidate term belongs. In our methods, we focus on three semantic categories of interest: (i) medications, (ii) signs and symptoms, and (iii) emotions and mental states.

Dataset

Following ethical guidelines in processing of online patient data, we focus on a popular, publicly available breast cancer forum with a large number of participants and obtained IRB approval. Posts from the publicly available discussion board breastcancer.org were collected [29,30]. At the time of collection, there were more than 60,000 registered members posting in 60 sub-forums. Our dataset consists of the most popular sub-forums. The extracted corpus for our analysis contains 26,153 threads corresponding to 253,231 posts. Overall, the corpus has 25.8M words for a vocabulary of 145K unique words. When considering only words that appear at least twice in the corpus, the vocabulary consisted of 75K words.

Lexicon Building

Choosing Seeds and Candidates. For each semantic category, we use an existing lexicon or a manually curated list of terms to gather a set of seed terms that are known to belong to the target category (e.g., medications). Using the forum corpus, we also extract a large number of candidate terms that may or may not be members of the target

semantic category. We customize our framework to our three semantic categories: medications, signs and symptoms, and emotions. The creation of these sets is described in Seed and Candidate Sets section below.

Table 1. Feature types used in the vector space model.

preceding word	A cell for each word in the vocabulary, indicating the number of times it appeared directly before the target term
word at -2	A cell for each word in the vocabulary, indicating the number of times it appeared 2 words before the target term
following word	A cell for each word in the vocabulary, indicating the number of times it appeared directly following the target term
word at +2	A cell for each word in the vocabulary, indicating the number of times it appeared 2 words after the target term
word within 3	A cell for each word in the vocabulary, indicating the number of times it appeared within 3 words before or after the target term

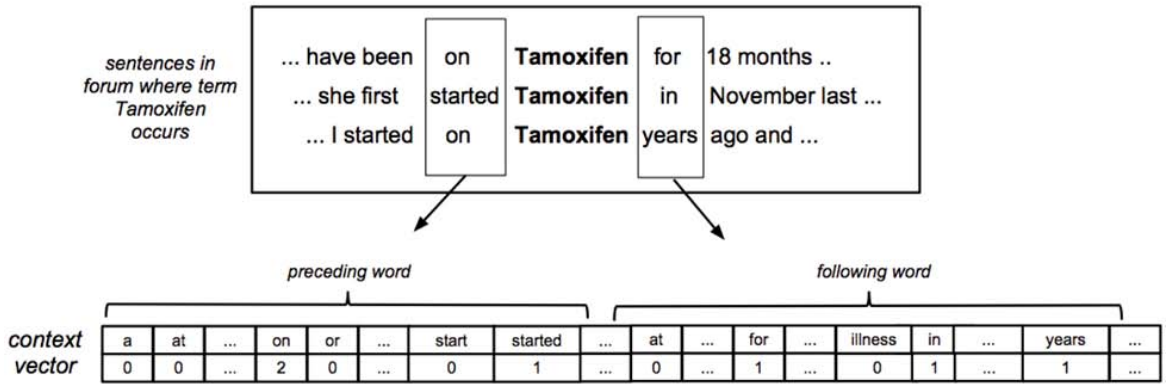

Figure 2. Part of the context vector for the seed term Tamoxifen. Each term context vector has a separate set of counts for preceding word, following word, word at -2, word at +2, and word within 3.

Constructing Context Vectors. Once the sets of seed and candidate terms have been selected, we employ a vector-space distributional similarity method to create context vectors for each term. The context vectors are derived from the vocabulary V found in the forum posts with the constraint that a word appears at least twice in the corpus. Each element in a term's vector contains a count of the number of times a word in V appeared in a certain context, such as directly preceding our term of interest. Because we use 5 contextual feature types, as described in Table 1, each context vector consists of 5|V| elements. We chose a set of local, highly specific contextual features to capture similarity in meaning and usage. For instance, in the example given in Figure 2, we can capture some of the data contained in exact patterns such as "been on X", as well as more general contextual features, such as the presence of the word started somewhere within 3 words of our target. This information helps the method find candidate terms that exhibit similar behavior to our seed terms, and are therefore likely to be in the same semantic category. These context vectors form the underlying representation in our method.

Creating a Representative Vector. In order to create a unified representation of a semantic category, the context vectors of the seed terms are merged into a representative vector for the category. Using vector addition, the individual context vectors are added. The vector is normalized by the number of seeds, producing a vector containing the average value for each of the seed vectors. A smoothing step is then performed, in which any values of the representative vector that are specific to only one seed are set to zero. This is intended to remove any contextual information that is unique to a single seed term and does not represent the semantic category as a whole. For example, assuming Arimidex is a seed term for medications, and it appears in the sentence "I have been on Arimidex (an aromatose inhibitor)", we will want to make use of the feature "preceding word on", since it is an indicator of a medication term, and will likely be shared by other seeds. However, the word aromatose is specific to the seed Arimidex, and we will discard the associated data unless it is shared by at least one other seed.

To further reduce noise and ensure a high-quality representative vector, a pre-filtering step is employed. The initial representative vector as created above is compared with each of the original seed term vectors using a cosine similarity metric [31]. If the similarity is below a certain threshold (.6 in our experiments), the seed term is

considered an outlier, and is removed. The representative vector is then re-created as described above using the filtered group of seed terms.

Calculating Similarity. A candidate term t is more likely to belong to a semantic category if its context vector is similar to the representative vector r for the category. Similarity is computed as the cosine metric between the two vectors. If the vector t is composed of (t_1, t_2, ..., t_n) and r is composed of (r_1, r_2, ..., r_n) then, their cosine is defined as

$$\text{Sim}(t,r)=\frac{t \times r}{||t|| \cdot ||r||} = \frac{\sum_{i=1}^{n} t_i \cdot r_i}{\sum_{i=1}^{n} t_i^2 \cdot \sum_{i=1}^{n} r_i^2}$$

The values of cosine similarity range from zero, indicating no similarity, to 1, indicating maximal similarity. Thus, our procedure scores each candidate term according to the similarity of its vector to the representative vector for the semantic category. The candidates can then be ranked in descending order of their similarity scores.

Seed and Candidate Sets

Seed sets are collected separately for each of the three semantic categories as described below.

Medications. To create a set of seed terms denoting names of medications, we use the comprehensive list of medications provided by RxNorm [32]. The list is then ordered by frequency of occurrence in the corpus, and terms appearing with low frequency in our corpus are removed (less than 50 in our experiments), resulting in a seed set of 137 medication terms.

The set of candidate terms for the medication category is defined initially as all out-of-vocabulary words in a standard English dictionary (dictionary from the Aspell program was used in our experiments), following the assumption that medication names are proper names, and thus not part of the standard English vocabulary. We only considered out of vocabulary terms from our corpus, which were frequent enough (50 times at least). This resulted in a set of 1,131 words as potential candidates for medication names.

Signs and Symptoms. We experiment with two medical lexicons for the construction of a set of seed terms denoting signs & symptoms. The first is the Unified Medical Language System (UMLS), where we use a list of all terms assigned to the 'sign or symptom' semantic type [11]. The second resource is SIDER, a list of terms denoting side effects extracted from FDA drug labels [33]. For each of these lists, we filter out all terms that are more than two words long. We then search for occurrences of the remaining terms in our data and extract all single word terms occurring more than 50 times, and all two-word terms occurring more than 20 times. This procedure provides the four seed sets described in Table 2. Despite the fact that both UMLS and SIDER seed lists share the most frequent term, there is relatively low overlap between them amongst these high-frequency terms (17 single-word terms, and 21 two-word terms).

Table 2. Number and average frequency of the terms in the four seed sets employed for detecting Signs & Symptoms, before and after (in parenthesis) the filtering procedures, along with the most frequent term in each seed set. The rightmost column specifies the coverage (cumulative frequency of all the terms inside the set) of each unfiltered seed set.

Seed Set	Size	Avg. Frequency	Most Frequent	Coverage
UMLS single word	84 (45)	1,205 (1,577)	pain	103,695
UMLS two words	136 (63)	134 (228)	hot flashes	37,702
SIDER single word	88 (51)	918 (1,418)	pain	80,780
SIDER two words	92 (38)	166 (335)	hot flashes	31,926

In the case of signs and symptoms, we cannot restrict candidates to out-of-vocabulary terms, as we did for medications, since signs and symptoms are often conveyed using standard-English words and are often multi-words. Instead, we consider any single-word or two-word term as a potential candidate, provided it appears frequently in our data (more than 50 times for single words, and more than 20 times for two-word terms), and consists of well-formed words (does not include numbers or other non-alphabetic characters).

In addition, for two-word terms, we perform another filtering step to reduce the number of candidates and improve quality. This filter is designed to remove multi-word terms that are very common in the data as a result of the frequency of the component words, rather than the term as a whole. For instance, the two-word term "and I" appears frequently in our data, but has little meaning as a unit, and its frequency is due to it being composed from two very common words. To filter such cases, we compare the probability of the term as a whole to the expected probability of the component words appearing in adjacent positions by chance, according to their individual probabilities, as shown in Equation 1. The ratio r between these probabilities is compared to a manually specified threshold t (in our

experiments, t = 20), and terms with ratios below the threshold are removed from the candidate list. After the selection and filtering procedures, we were left with a candidate list of 10,844 single-word candidates, and 37,015 two-word candidates.

$$\text{Eq. (1)} \quad r(\text{word1 word2}) = \frac{p(\text{word1 word2})}{p(\text{word1}) \cdot p(\text{word2})} \qquad p(x) = \frac{\#\text{ occurrences of x}}{\text{size of data}}$$

Emotions. While there exist terminologies for emotions [34], we experimented with a very small seed set for emotions. Part of our motivation is to test the robustness of our method to discovering new terms when a limited terminology or none is available. Given the most frequent words in the corpus of posts, we manually selected 10 adjectives as a seed set, which conveyed an emotional state randomly: *scared*, *grateful*, *sorry*, *fatigued*, *guilty*, *comfortable*, *nervous*, *confused*, *afraid*, *and happy*. Following the filtering step described above to compute the representative vector, there were six emotion seed terms left: scared (frequency of 5,512 occurrences in the corpus), grateful (frequency 1,445), sorry (frequency 20,768), confused (frequency 1,807), afraid (frequency 3465), and happy (frequency 11,338). For the sake of reproducibility, we replicated the experiments with different seed sets chosen randomly and obtained very similar results to the ones given this instance of seed set, and thus only report on these results.

Experimental Setup

The output of our method for a given semantic category is a ranked list of terms, which can augment a terminology of known lexical variants for the category (ranking is based on the terms' similarity scores to the given semantic category). We asked domain experts (two clinicians and one health psychologist) to review the lists for each of the three categories and tag each ranked term as a true positive (indeed a term that belongs to the semantic category) or a false positive (a term that does not belong to the semantic category). We report on the Precision at K[31], a standard evaluation metric for retrieval tasks in which the overall gold standard is unknown in advance – with different values of K for the top-K returned results, from K=10 to 50. We also report the cumulative coverage of the true-positive terms retrieved at the different K – that is, considering only terms that are not seeds. The coverage is a sanity check that the effort spent on discovering these terms pays off in terms of content that would have been ignored otherwise. For medications, the experts also encountered a number of terms that fell in a gray area. For instance, terms which were general names of treatments, or categories of medications, such as anthracyclines, a class of antibiotics. There were also terms indicating various drug cocktail treatments, as well as names of dietary supplements alternative treatments. Thus, for medication, we report two types of Precisions at K: a strict evaluation, which represents whether the ranked terms were medication names indeed, and one with a less strict definition of medication, which includes medication classes and drug cocktails.

Results

The code and the generated lexicons are available to the research community at *people.dbmi.columbia.edu/noemie*.

Augmenting an Existing Lexicon

Medications. In Table 3 we list the top ten terms according to the similarity with the representative vector for the medication category, along with their similarity score and frequency in the corpus. For the most part, the system correctly identifies terms indicating medications. There are misspellings (e.g., tamoxifin, benedryl, femera) and abbreviations (e.g., tamox) of medication names. The terms bisphosphonates and hormonals indicate classes of medications.

Table 3. List of top 10 retrieved medication terms not included in seed set, along with their similarity score and their frequency.

Retrieved term	Sim. score	Freq.	Retrieved term	Sim. score	Freq.
Tamox	0.888	6,107	bisphosphonates	0.821	549
Hormonals	0.888	1,012	carbs	0.821	326
Tamoxifin	0.880	666	mammos	0.817	704
Benedryl	0.831	402	femera	0.815	452
Fatique	0.827	108	lymphedema	0.815	2,656

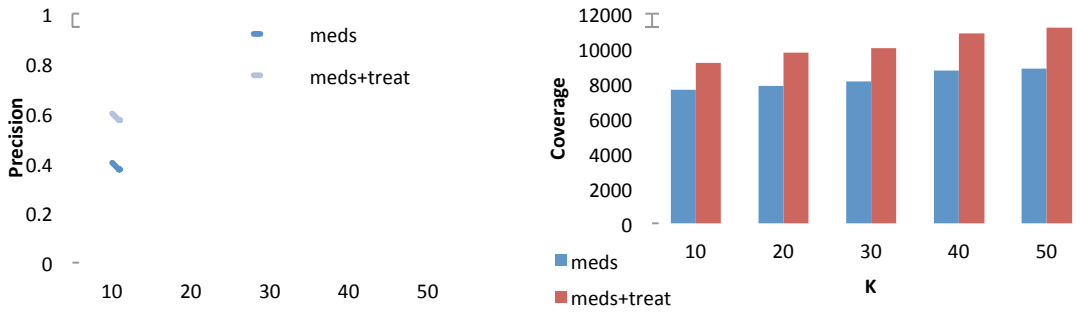

Figure 3. Precision (left) and number of instances covered (right) for the top K={10,20,30,40,50} retrieved terms not in the seed set for medication and treatments (meds+treat) and medication names only (meds).

We can see four classification errors: fatique, carbs, mammos, and lymphedema. The first is a rare misspelling of fatigue in the dataset, with thus little power to be categorized correctly. The term carbs is used in a similar fashion to many medications, since it is an ingested compound and forum users often discuss its effect on their health, much like they discuss medications. In general, we observed that various types of dietary supplements were common in our results for this reason.

Figure 3 shows the precision of the classification as we go down the list of retrieved terms (and following our experimental setup where only words outside of RxNorm were assessed for validity). Coverage ranged from 9,188 for K=10 to 11,191 occurrences for K=50 for medications and treatments, and ranged from 7,627 (K=10) to 8,859 occurrences (K=50) for medication names alone.

Signs and Symptoms. Table 4 shows the top 10 single-word and two-word terms retrieved as Signs and Symptoms retrieved when using SIDER as seed set. Figure 4 shows precision and coverage at K for the Signs and Symptoms category using either UMLS or SIDER as seed set.

Table 4. Top 10 single- and two-word terms retrieved as Signs & Symptoms using SIDER as a seed set.

Retrieved term	Sim. score	Freq.	Retrieved term	Sim. score	Freq.
itching	0.954	807	joint pain	0.985	2,213
caffeine	0.950	342	mouth sores	0.966	604
chemo	0.950	76,737	body aches	0.959	221
depression	0.950	2,575	acid reflux	0.958	205
discomfort	0.945	1,520	nose bleeds	0.954	131
bleeding	0.942	1,376	hair loss	0.952	1,549
bruising	0.942	336	bone aches	0.949	119
soreness	0.935	476	stomach problems	0.948	101
exhaustion	0.935	248	extreme fatigue	0.947	110
surgery	0.934	35,831	mood swings	0.945	309

As mentioned in the Methods section, we made use of two resources to develop two separate seed sets for this semantic category. In the figure, we see that the different characteristics of the seed set (see Table 2), result in differences in performance for our system. The UMLS seed set has better coverage than Sider on single-word terms, for a similar number of words. This means that the single-word terms in the UMLS are more suited to our domain, and this results in higher coverage and precision for the output of our system. For two-word terms the situation is reversed. The SIDER seed set has similar coverage, but is significantly smaller than the UMLS one (see Table 2). This means that the seed terms are more suited to our domain. For two-word terms, we get better coverage and precision when using SIDER as a seed.

There is another important difference worth noting between single-word terms and two-word ones. In the case of single word terms, the coverage of both the lexicons we employ is quite high. This means it is difficult to find new terms not mentioned in the lexicon, and these are found with lower confidence. This is also the reason for relatively low precision for single-word terms in this semantic category (the precision is measured only for the new terms). For two-word terms, on the other hand, initial coverage of the seed sets is quite low. There are many terms in the data that are strong members of this semantic category, but are not mentioned in the lexicons. This means the system can discover high quality new terms, with higher coverage and better precision.

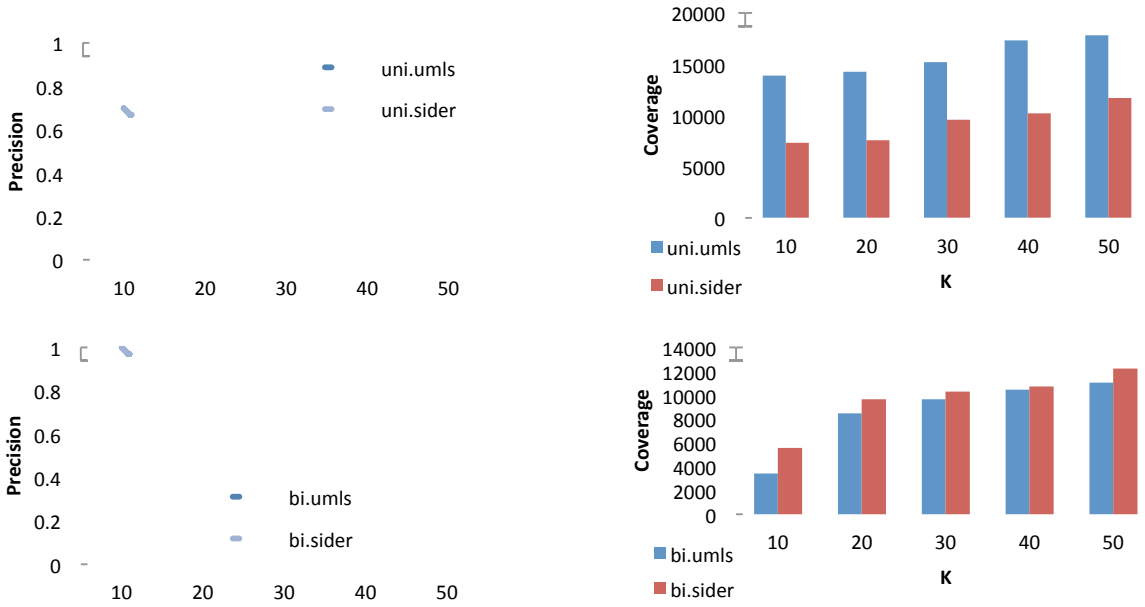

Figure 4. Precision (left) and number of instances covered (right) for the top K={10,20,30,40,50} retrieved single-word signs & symptoms (top) and two-word signs & symptoms (bottom), reported for UMLS and Sider as seed set.

Emotions. Table 5 shows the list of top-10 retrieved emotion terms from the small seed set of six emotion terms. All terms are high-frequency terms in the corpus, except for greatful. Interestingly, the misspelled greatful, despite its low frequency had a high similarity to emotions probably because of its correct spelling grateful was one of the seed term. The precision is much higher with emotions than with the other two semantic categories medications and signs and symptoms, starting at 100% at K=10 and decreasing to 78% at K=50. For this category, we evaluated up to K=100, with a precision of 64%. Moreover, the coverage of the true-positive emotion terms ranged from 20,076 for K=10 to 51,281 for K=50. This indicates two findings: (i) terms relating emotional states are highly frequent in our corpus, confirming that much emotional support is exchanged amongst the forum members; and (ii) our method is particularly good at discovering new terms when provided with a very small seed set (in this case a set of 6 chosen terms).

Table 5. List of top 10 retrieved emotion terms not included in seed set, along with their similarity score and their frequency.

Retrieved term	Sim. score	Freq.	Retrieved term	Sim. score	Freq.
glad	0.878	12,414	thankful	0.741	1,273
relieved	0.847	922	desperate	0.721	252
excited	0.780	1,035	delighted	0.719	152
thrilled	0.769	779	greatful	0.716	80
sad	0.745	2,994	saddened	0.698	175

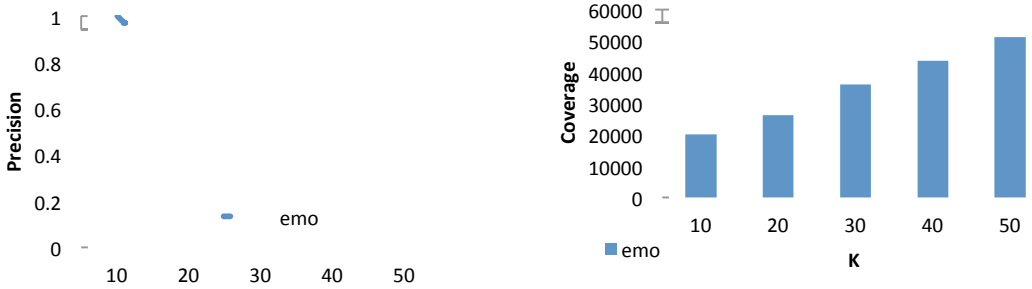

Figure 5. Precision (left) and number of instances covered (right) at K={10,20,30,40,50} for the retrieved emotion terms not in the seed set.

Sensitivity to Choice of Seed Set

A common concern when using statistical methods that rely on seed terms is the sensitivity of the method to the choice of seeds. To investigate this issue in our framework, we compared the results of using a variety of different seeds, and examined the effect on the terms retrieved by the system.

First, we compared the output of the system when using the seed set based on UMLS terms to the output when using seeds from SIDER. Despite low overlap between the two seed sets, the output of the system was similar for both. When comparing the top hundred most highly scored terms, we found an overlap of 91% in the output for two-word terms, and 89% for single word terms. This indicates that the semantic category we are looking for – terms indicating signs and symptoms – is a well-defined one, with specific usage patterns in the data. A practical implication is that any seed set containing good representatives of the semantic category can be used to successfully retrieve other terms in a fairly robust fashion.

We also experimented to discover if single-word terms could be used as seeds to retrieve multi-word terms in the same semantic category. We used the SIDER single-word seed set to rank the two-word candidates. In this case, however, we found much lower correspondence with the output of the two-word seeds (60% when compared to the UMLS two-word seed group, and 57% compared to the Sider seed). These findings indicate that single-word terms describing side effects are used in a different manner than multi-word expressions, in terms of immediate context, and that it is important to use a seed set of the same type as the candidates that are being ranked (single-word seeds for single word candidates, and multi-word terms as seeds for multi-word candidates).

Finally, on the basis of the success of a small, manually selected seed set for the emotion category, we experimented with using a similar strategy for the medication and signs and symptoms categories. We randomly shuffled the posts in our data and manually selected the first ten terms we saw that belonged to each category – i.e., without any reliance on any dictionary. We re-ran our method by filtering these small seed sets and constructing context vectors, and thus the resulting seed sets were at most ten words randomly chosen for each category. Table 6 shows the random seed sets in each category. The starred terms were filtered out automatically at the pre-filtering step when creating the representative vector for a given category.

For medication names, using a small set of random seeds was very successful, achieving 66% precision on the top 50 ranked results (74% if names of treatments are included), as compared to 44% and 62% when using RxNorm as basis for the seed. This demonstrates that if the target class is well defined, our method can learn accurate information from only a small number of examples, and a large, manually compiled lexicon is not necessary. For the category of signs and symptoms, the small randomly selected seed sets were also very effective. For single-word terms, the small seed set achieved 44% precision on the top 50 ranked results, significantly higher than that achieved by using UMLS and SIDER as seed sets, where the accuracy was 38% and 34%, respectively. For two-word terms, the randomly selected seed set achieved similar precision to using UMLS (62% on the top 50), but was not as effective as using SIDER (88%).

Table 6. Random seed set for Medications, Signs and Symptoms single words, and Signs and Symptoms two words. The terms with asterix were filtered out automatically during the step for construction of the representative vector.

Medications	**Signs & Symptoms Single word**	**Signs & Symptoms Two words**
tamoxifin	Pain	allergic reactions
herceptin	Leakage	mood swings
taxol	Cyst	* distended abdomen
carboplatin	Nausea	mouth ulcers
taxotere	neuropathy	hot flashes

Discussion

Principal Findings. The primary objective of this study was to evaluate the use of lexical semantics in creating lexicons for use in content analysis of online health communities. Existing lexicons, like RxNorm, UMLS, and SIDER are fairly static resources, with potentially low coverage of the particular sublanguage of online health communities, whose informality often includes unique jargon, misspellings and abbreviations created by

community members. Our method aims to fill in these gaps, by generating lexicons to represent the language of members in a given community with respect to different semantic categories.

Our study suggests that using context vectors trained on a small seed set is a viable, robust method to expand existing medical lexicons across a range of potential semantic categories. The method was robust across semantic categories as long as seeds were good representatives of those categories. Furthermore, we showed that the seed set can be very small (e.g., six terms like in our experiments with detecting emotion terms) and still generate viable lexicons with good coverage. Finally, our experiments with UMLS and SIDER suggest that seed set selection should take into account surface characteristics like number of words in phrase. Finally, our study's experimental setup assessed the validity of only terms that were not already covered by existing lexicons. Thus, in the case of a semantic category and a lexicon with good coverage, our method has less opportunity to identify new terms (e.g., RxNorms and medications), but when the existing lexicons are scarce, our method identifies new terms with high accuracy (e.g., emotions).

Implications for Quantitative Research on Online Health Communities. As online health communities become a standard data source for mining information about patients, the underlying lexicons used to retrieve or assess prevalence of different terms must be representative of the way community members communicate. The lexicons we generated contain variations of known terms, which would be difficult to discover otherwise, as well as terms, which are not covered by existing lexicons. By making our code and generated lexicons available, we hope to contribute a valuable resource to the research community.

Limitations. Although the current work can be viewed as an important first step for augmenting lexicons to reflect online health community sublanguage, the results do not have high enough precision to be used without a manual annotator in the loop. Our hope is that the generated lexicons are still useful to researchers, since it is much easier to cross off terms in a generated list that should not in the lexicon, than it is to browse through thousands of posts manually to identify terms representative of the way members communicate (in our experiments, manual review was short and easy, on average 20 minutes per 100 terms). In our future work, we plan to experiment with other unsupervised methods and improve the accuracy of our generated lexicons. Second, our experiments focused on three specific semantic categories. While we chose them, because they are important types of content to know about for the content analysis of a breast cancer community and results indicate that a small seed set can generate valid lexicons for all three categories, we have not generalized our work to other types of semantic categories. Finally, the experiments presented in this paper focus on a single community as underlying corpus. In the future, we would want to compare lexicons learned from different communities specific to the same disease. We have conducted preliminary experiments indicating that, for instance, the lexicon learned in one breast cancer community is a useful resource for another, but further work is needed to generalize this finding. We also plan to test our method on other health communities specific to diseases different from breast cancer, to test the generalizability and robustness of our method.

Conclusion

This paper describes a method to generate a lexicon to represent the language of patient users in a given online health community with respect to specific semantic types. We experiment with a breast cancer forum and detect terms that belong to three semantic types: medications, symptoms and side effects, and emotions. Experimental results show that our method captures the sublanguage of members in these communities with more coverage than existing, general-purpose terminologies do. Furthermore, even with a very small number of seed terms, the method can generate reliable lexicons. This work contributes a building block to quantitative research on online health communities.

Integrated Multisystem Analysis in a Mental Health and Criminal Justice Ecosystem

Abstract
Patients with a serious mental illness often receive care that is fragmented due to reduced availability of or access to resources, and inadequate, discontinuous, and uncoordinated care across health, social services, and criminal justice organizations. These gaps in care may lead to increased mental health disease burden and relapse, as well as repeated incarcerations. Further, the complex health, social service, and criminal justice ecosystem within which the patient may be embedded makes it difficult to examine the role of modifiable risk factors and delivered services on patient outcomes, particularly given that agencies often maintain isolated sets of relevant data. Here we describe an approach to creating a multisystem analysis that derives insights from an integrated data set including patient access to case management services, medical services, and interactions with the criminal justice system. We combined data from electronic systems within a US mental health ecosystem that included mental health and substance abuse services, as well as data from the criminal justice system. We applied Cox models to test the associations between delivery of services and re-incarceration. Using this approach, we found an association between arrests and crisis stabilization services in this population. We also found that delivery of case management or medical services provided after release from jail was associated with a reduced risk for re-arrest. Additionally, we used machine learning to train and validate a predictive model linking non-modifiable and modifiable risk factors and outcomes. A predictive model, constructed using elastic net regularized logistic regression, and considering age, past arrests, mental health diagnosis, as well as use of a jail diversion program, outpatient, medical and case management services predicted the probability of re-arrests with fair accuracy (AUC=.67). By modeling the complex interactions between risk factors, service delivery and outcomes, we may better enable systems of care to meet patient needs and improve outcomes.

Introduction

The mental healthcare system in the United States is fundamentally broken – it is fragmented, inconsistent, underfunded, and rapidly deteriorating. Dominated by a lack of both consistency and continuity of care, the system allows many clients to mentally decompensate, ultimately leading to three negative crisis outcomes – homelessness, emergency hospitalization and incarceration. This fragmentation in the treatment of the mentally ill is particularly evident when one considers that it has been estimated that between 44 and 61 percent of jail inmates in the United States have a mental health problem (James et al Mental health problems in prison). Many individuals with severe mental illness are released from prison every year in the United States and re-enter the community with a need to continue treatment for their mental health issues. Continuous mental health treatment of these individuals may help prevent relapse and recidivism.

Lack of continuous care for adults with serious mental illness may not only result in more decompensation and crisis as the individual navigates the mental health, social, and criminal justice systems, but it also limits our understanding of the impact and interaction between modifiable risk factors and access to multiple services on patient outcomes such as re-arrest. Given that different agencies often maintain isolated datasets, the fragmentation of data systems and lack of access to continuous patient-level data means that it is difficult to collate data across health, social, and criminal justice agencies to evaluate the interplay between multiple services and outcomes. There is a critical need to evaluate patient-level and service-level data across multiple agencies in order to understand the mechanisms through which we may intervene to prevent or delay psychiatric crises.

Previous work evaluated data from US Medicaid claims files and arrest records and found a reduced risk of re-arrest with receipt of outpatient services[1,2,3] and psychotropic medication possession[3] in adults with mental illness. Other research using county and statewide criminal justice records and archival data from health and social services found that individual risk factors including being homeless, not having outpatient mental health treatment, and having involuntary psychiatric evaluation in the previous quarter, and being black, younger than 21 years and having a co-occurring substance abuse problem increased the odds of arrest[4].

Recent studies for other medical applications have used electronic medical records data to establish predictive models for illness severity in various disease domains, including preterm infants[5], congestive heart failure[6], septic shock[7] and HIV[8].

In this study, we describe an approach to modeling the interplay among services and outcomes across an ecosystem of medical and social services providers and the criminal justice system in which there is a constant flow of individuals with serious mental illness in and out of the criminal justice system. We explored associations between the occurrence of arrest and crisis services outcomes tested using hazard modeling with both fixed- and time-dependent covariates. We demonstrate the utility of such a combined dataset for predictive modeling by training and testing a model for arrest prediction.

Preliminaries

In this study, the sets of covariates used for prediction include both basic risk factors as well as indicators of access to specific services. Cox models were applied to test the associations between access to services and outcomes. Predictive models were constructed using elastic net regularized logistic regression.

Association analysis using Cox models

Cox proportional hazard models were used for testing associations between risk factors and the expected time for failure events to occur[9].This association is modeled using a *hazard rate* that represents the amount of risk as a function of time. The effect of each risk factor is assumed to be multiplicative with respect to the hazard rate.

In addition to predicting the effect of services given immediately after release, we examine the effect of continuous access to services. These tests involve time dependent covariates such as access to services in every month after

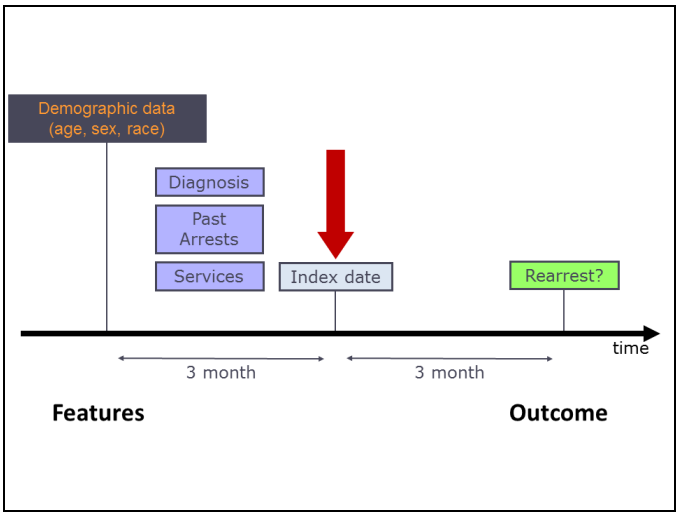

Figure 1: Data preprocessing and feature extraction framework

release from jail. Association tests with such covariates were performed using extended Cox models (see [11] for more details).

Predictive modeling using elastic nets

An elastic net is a method that allows classical regression models to deal with high dimensionality of observations.

This method performs data-driven variable selection and results in a sparse model that includes the most informative covariates. Learning in such models involves tuning of two parameters: (1) alpha – which controls the sparseness and stability of the model, where a higher alpha increases the tendency of the learning algorithm to filter out non-informative covariates; (2) beta – a regularization parameter that prevents over-fitting of the model to the data which is employed to obtain optimal generalization performance. These parameters are usually tuned using internal cross-validation on a training data set. The accuracy of the model is assessed on a test set. For more details see[12].

Methods

Framework – integrated view of patients ecosystem

This study uses information extracted from electronic systems resident within a mental health ecosystem in the southern US. This included data used to support the claims process for medical and social services delivered to mental health and substance abuse patients, and data collected by the criminal justice system. All individual patient data used for the analysis were collected after obtaining appropriate consents and agreements, and personal information was removed to protect patient privacy.

Patient data collected for this analysis span 21 months and describe the engagements that patients have with service providers in the ecosystem. An essential part of analyzing such longitudinal data is defining an index date, where data collected before that date serve as input to decision making and data from after that point in time define the outcome values and characterizes the treatment. We then define the target populations on which to focus and a quantitative outcome measure. Finally, we extract and filter features and risk factors to drive the modeling (Figure 1).

The main outcome addressed in this study was a re-arrest, as experienced by individuals that had become involved in the criminal justice system. The study explored two main questions: (i) What are the modifiable and non-modifiable risk factors associated with this outcome? (ii) How well can we predict the likelihood of re-arrest using such risk factors? Our approach employed an association analysis to explore the answers to the first question and a machine learning analysis to explore the answers to the second question.

We further test the association of various risk factors to admission to acute service, namely crisis stabilization unit.

We hypothesized that the relationship between mental health services and the criminal justice system may be bidirectional; to explore this hypothesis, we test associations between various risk factors including previous arrest records and the risk of admission to acute mental health treatment facilities (namely crisis stabilization unit).

Data sources

Datasets for mental health and substance abuse admissions and events were included which span the time window from October 1, 2010 to June 30, 2012. All mental health admissions before October 1, 2010 have been recorded with an admission date of October 1, 2010. Substance abuse admissions data span the period between July 1, 2009 and June 30, 2012. In this study we focus on Seriously Persistent Mentally Ill (SPMI) individuals that have one of the following diagnoses:

- Bipolar disorder (ICD9 codes: 296 to 296.19 and 296.40 to 296.99)
- Schizophrenic disorder (ICD9 codes: 295 to 295.99 and 297 to 298.99)
- Major depression (ICD9 codes: 296.20 to 296.39)

The dataset includes data on an SPMI population of 29,558 individuals.

Arrest data were supplied by the Department of Law Enforcement and was extracted from the Criminal Justice Information Services (CJIS). These data span a period from January 1, 2007 to September 6, 2012, and include records on 184,470 individuals. Out of these, 5,148 overlap with the SPMI population in the health ecosystem studied. The court runs a program that helps identify and divert detainees with a mental illness into a Jail Diversion Program (JDP), which seeks to reintroduce individuals into a sustained care environment, combining mental health and housing services as part of a structured year-long engagement. The court provided a list of participants for approximately ten years, overlapping the data contained in the other data sources.

Population Selection Criteria
To analyze the relations between arrest and behavioral health service events we focused on a subset of the adult population having records both in the CJIS and mental health ecosystem datasets. We excluded 281 individuals from this cohort because of inaccurate and inconsistent timeline data. Out of the remaining individuals, a total of 3,274 were released from an arrest after October 1st, 2010, which is the starting date of the mental health services recorded in the dataset. Of these, 3,171 were adults at the time of release[a].

In addition to viewing arrest as an outcome, we analyzed the association of past arrests with the outcome of admission to an acute mental health treatment using the SPMI cohort. We excluded individuals whose first recorded admission had ambiguous or unknown dates, creating a subset of 15,930 subjects. Of these, we further focused on the adult population (N=14,228).

Statistical Analysis

Association between non-modifiable risk factors, receiving services after release from jail, and the risk of re-arrest
The initial association analysis examined non-modifiable risk factors including gender, age, race, mental health diagnosis and past arrests using a Cox proportional hazard model. The association of receiving different service types with the risk of re-arrest was evaluated, adjusting for these non-modifiable risk factors. The dataset contains thirty nine types of services, out of which fourteen service types were given to more than 20 patients in the cohort. Each of these service types was represented using an *indicator covariate* equal to one if an individual received the service at least once in the first quarter after release from jail and equal to zero otherwise.

Continuous access to services
Extended Cox models were used to examine the association of services given throughout the entire period after release from jail to the risk of re-arrest. More specifically, for each patient, all release dates after Oct 1, 2010 were listed and corresponding re-arrest dates were identified (or, if the patient was not re-arrested, the end-of-study date was determined). Starting from each such release date, the number of times each service was given to the patient in each consecutive 90 day time period was tabulated.

Subsets of these time-varying covariates, in addition to the non-modifiable factors, were then used to infer the parameters of extended Cox models. In particular, models were constructed with the following features:

1. An indicator covariate identifying whether or not a specific service was given within the last ninety days (including non-modifiable risk factors) to predict re-arrest within the coming ninety days.
2. An indicator covariate identifying whether or not a specific service was given since the last release from jail (including non-modifiable risk factors) to predict re-arrest within the coming ninety days.

Predictive modeling using elastic nets
To test the predictability of the arrest outcome, data were partitioned into a training set which contained approximately 80% of the cohort and a test set which contained the remaining 20%. An elastic net regularized regression model was used where alpha was tuned to balance sparseness and stability on the training set.

Because the goals of the analysis were set to predict re-arrest probability in the second quarter after release, the target population was similar to the one described in re-arrest risk factor analysis. However, individuals were excluded for which data were not available for two quarters. Applying this additional criterion, the cohort size was established as 1,679 individuals in the training set and 421 in the test set. We evaluated the predictive power of the model using a receiver operating characteristic (ROC) curve which compares the likelihood of correctly and incorrectly predicting re-arrest.

[a] Due to the removal of exact birth dates, we use estimated ages at different time points. Here we include individuals with estimated age at release > 18.

Results

Preliminary associations of demographic and historical factors with re-arrest

The association between non-modifiable risk factors was estimated using Cox proportional hazard models. Past arrests factors were modeled as indicator variables whose value was one if the individual was arrested and released from jail between January 2007 (start date of the CJIS data) and October 2010, and zero otherwise.

Preliminary associations (i.e., without adjusting for other variables) between these factors and the risks of re-arrest are summarized in Table 1. Associations with p-value < 1e-4, will remain significant at a 0.05 level after a Bonferroni correction for 500 hypotheses. In particular, schizophrenia, history of arrests, male gender, black race, and younger age are shown to be risk factors for increased likelihood of re-arrest, in agreement with previous studies[4].

Table 1. Preliminary associations between baseline characteristics and the risk of re-arrest

Factor	P-value	Crude Hazard ratio	95% confidence interval
Gender (Female vs. Male)	<1e-4	0.71	0.63-0.81
Race (Black vs. Other)	<1e-4	1.31	1.18-1.47
Diagnosis (vs. Major Depression)			
Bipolar Disorder	0.02	1.22	1.03-1.45
Schizophrenic Disorders	<1e-4	1.50	1.30-1.74
Past arrests	<1e-4	2.04	1.80-2.31
Age	<1e-4	0.99	0.99-1.00

Association between arrests and crisis services

In the ecosystem studied, a large proportion of individuals were first admitted into the system of care through a Crisis Stabilization Unit (CSU; representing more than 30% within a week from first admission). A subset of the population was examined that did not record an admission to a CSU in the first quarter (N=10,307). In this sample, the association of a later CSU admission with past arrests, adjusted for age, gender, race and mental health diagnosis was significant (p<1e-4) with a high hazard ratio of 2.46 (95% confidence interval 2.00-3.02).

Services associated with reduced risk of re-arrest

To test associations with services given in the first quarter after release inmates that were re-arrested within the quarter were excluded. Out of 3171 adults, a total of 2,377 (~75%) remained out of jail during this period. This test therefore was able to examine conditional probabilities of future re-arrests given that the individual remained out of jail in the first quarter.

Associations between service indicator variables and the risk of re-arrest adjusting for gender, age, race, mental health diagnosis and past arrests as defined in the baseline test model were also tested. Results, summarized in Table 2, indicate an association of case management and medical services with a reduced risk of re-arrest[b]. Figure 2 presents Kaplan-Meyer plots of arrest probability for individuals that stayed out of jail in the first quarter after release, given their access to these services in this quarter.

Table 2. Associations among services and the risk of re-arrest

Factor	N	P-value	Adjusted Hazard ratio	95% confidence interval
Case management	172	0.00018	0.45	0.30-0.68
Medical services	491	<1e-4	0.59	0.47-0.74
Outpatient group[c]	45	0.038	0.46	0.22-0.96

[b] The CJIS data include both booking and arrest records. The table above refers to booking dates. Using arrest dates instead, gives a 0.48 hazard ratio for case management and 0.64 for medical services.

[c] This association is not considered significant as it does not pass a multiple hypothesis correction.

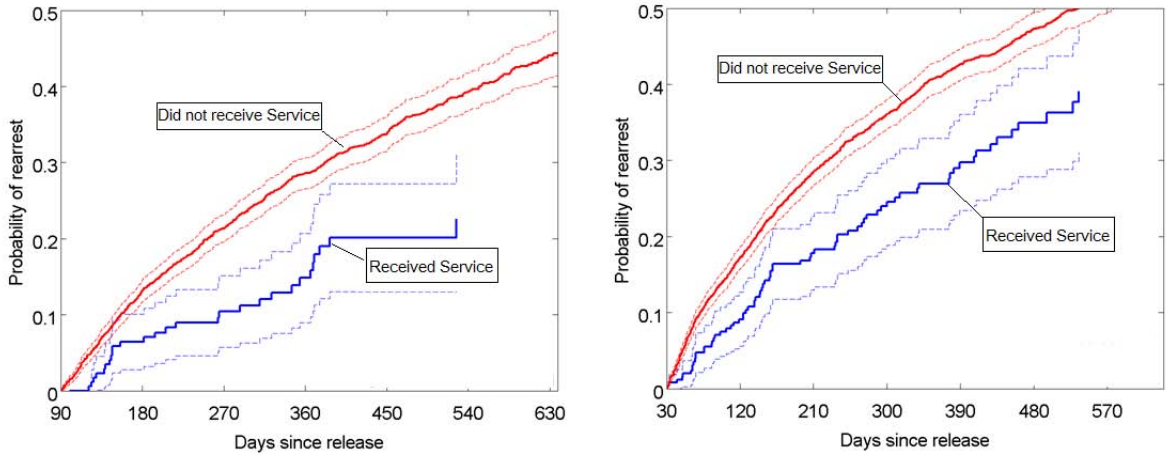

Figure 2: Kaplan-Meyer estimators for arrest probability demonstrating the effect of case management (left) and access to medical services (right)

Continuous access to care and continuous monitoring of patients states

Extended Cox model analysis shows that the indicator for Medical Services, either in the past 90 days or since release, is significantly associated with a reduced risk for re-arrest, with hazard ratios of 0.68 (confidence interval 0.58-0.80, p-value<1e-5) and 0.67 (0.58-0.78, p-value<1e-7), respectively. Conversely, the indicator for Crisis Stabilization, in both time periods, is associated with an elevated effect on the risk of re-arrest, with hazard ratios of 1.43 (confidence interval 1.22-1.69, p-value<1e-4) and 1.23 (1.07-1.42, p-value=0.003), respectively. Schonenfeld residuals for all these indicators, except for Crisis Stabilization in the past 90 days, attested to the correctness of the proportional hazard assumption.

Predictive Modeling of Re-Arrests

Elastic net regularized logistic regression models were trained using a training set containing 1,679 individuals. The regularization parameters alpha and beta were tuned using cross validation and the model was retrained on the entire training set with optimal parameters. Testing this model on a test set of 421 individuals resulted in an AUC of 0.67 (see 'Full model' in Figure 3 below). Informative covariates selected by the training procedure included age, past arrests, mental health diagnosis, enrollment to the JDP as well as utilization of outpatient group services, medical services and case management. The probability of re-arrest is modeled as function of a weighted sum of these factors. As the ROC curve in Figure 3 indicates, the model correctly predicts 50% of individuals in the ecosystem at risk for re-arrest based on the defined risk factors, while mis-characterizing 30% of individuals at risk. To assess the predictability of re-arrest from basic demographic data, namely, age, gender and race, we trained a simpler model using the same cohort and an elastic net model. This model was inferior to the full model, with an AUC of 0.60 and 42% true positive rate at the 30% false positive threshold ('Basic model' in Figure 3). The difference between the two ROCs illustrates the additional predictive power of the judicial and mental health related factors.

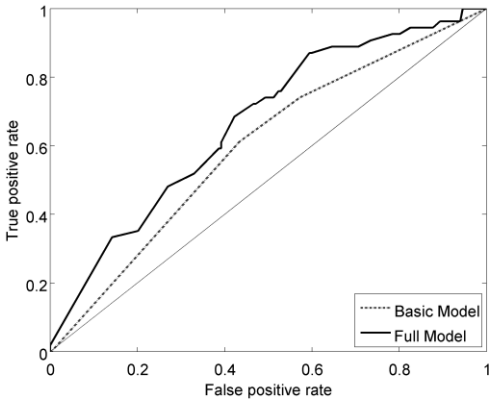

Figure 3: ROC curve of elastic net predictive model for re-arrest outcome

Discussion

In this analysis, we found that characteristics including schizophrenia, history of arrests, male gender, black race, and younger age were risk factors for increased likelihood of re-arrest. Further, factors such as past arrests increased the risk of having a crisis stabilization event, whereas receipt of case management services or medical services following release from jail reduced the likelihood of re-arrest. Using this knowledge of non-modifiable and modifiable core risk factors associated with re-arrest, we developed a model that predicted the probability of re-arrest after the first 90 days of release from jail with reasonable accuracy.

These findings support previous work that examined US Medicaid claims and arrests records, and other research, which found that factors associated with greater risk of arrest include minority racial-ethnic status[3] or African American race[1,4], male gender,[3] younger age. [3] and receipt of outpatient services (which may have included individual or group behavioral health services, medication checks,[2] and/or case management[1,3]). While we found that the receipt of medical and case management services predicted a reduced risk of arrest, the receipt of other behavioral health services such as outpatient group therapy was not considered significant. These findings therefore extend previous research by considering the independent contributions of case management and medical services in predicting re-arrest. However, while our findings suggest that providing case management and medical services within 90 days of release from jail may reduce the chance of re-arrest in adults with serious mental illness, it is important to remember that these are correlational results, and differential assignment to services may be due to some unmeasured variable associated with a better prognosis.

In the current analysis, we chose to include individuals with major mental illness including depression, bipolar disorder, and schizophrenia because these diagnoses are found at a high rate in the criminal justice system.[13] Future work should explore the role of other mental health diagnoses in predictive models, as well as the effect of comorbid conditions. Future studies should also be conducted to refine the model by integrating other sources of data (e.g. additional medical claims, pharmacy and hospitalization data). In the current analysis, medical services included primary medical care, psychiatric assessment and services, and administration of psychotropic drugs and other medications. It would be of particular interest for future analyses to examine the specific role of pharmacy/medication administration in predicting re-arrest, particularly given recent data showing that post-hospitalization medication possession reduced the likelihood of arrest in adults with serious mental illness in a Florida Medicaid population.[3]

Understanding how we can best intervene to address modifiable risk for incarcerations may be important not only for improving the quality of life of adults with serious mental illness, but also for reducing costs within the systems that support their care. Using Florida Medicaid data and records from Florida's Department of Children and Families (DCF) and the Florida Department of Law Enforcement (FDLE), Van Dorn et al (2013) compared the costs associated with criminal justice system involvement with those for mental health treatment, and found that overall system costs were lower for adults with serious mental illness who did not get arrested.[3] Taken together with our current findings, the results suggest that increasing the provision of case management and medical services in a

SPMI population at risk for arrest may be an important strategy for reducing overall system cost burden. This should be explored in future research.

Conclusions

In conclusion, our findings illustrate the complex interactions between modifiable and non-modifiable risk factors and delivery of services on outcomes in adults with serious mental illness. The data-driven approach defined in this analysis demonstrates the value of integrating data across disparate datasets from healthcare, social services, and criminal justice agencies. Further development of this predictive model may help us to identify those individuals who are at greater risk for re-arrest and crisis, and to intervene in a timely manner to help improve outcomes for the mentally ill. A reduction in arrests in this seriously mentally ill population may not only improve patient outcomes, but also diminish the burden on the judicial and health systems.

TagLine: Information Extraction for Semi-Structured Text in Medical Progress Notes

Dezon K. Finch, PhD,[1,2] James A. McCart, PhD,[1] Stephen L. Luther, PhD[1]
[1]James A. Haley Veterans Hospital, Tampa, FL; [2]University of South Florida, Tampa, FL

Abstract

Statistical text mining and natural language processing have been shown to be effective for extracting useful information from medical documents. However, neither technique is effective at extracting the information stored in semi-structure text elements. A prototype system (TagLine) was developed to extract information from the semi-structured text using machine learning and a rule based annotator. Features for the learning machine were suggested by prior work, and by examining text, and selecting attributes that help distinguish classes of text lines. Classes were derived empirically from text and guided by an ontology developed by the VHA's Consortium for Health Informatics Research (CHIR). Decision trees were evaluated for class predictions on 15,103 lines of text achieved an overall accuracy of 98.5 percent. The class labels applied to the lines were then used for annotating semi-structured text elements. TagLine achieved F-measure over 0.9 for each of the structures, which included tables, slots and fillers.

Introduction

The analysis of text from the electronic health record (EHR) is an important research activity in medical informatics and particularly in the Veterans Healthcare Administration (VHA) because of its large integrated EHR. A wide variety of methods have been employed to extract information from text. Information retrieval (IR) and information extraction (IE) have been shown to be useful for detecting patterns in patient care[1], patient treatment patterns[2] and outcomes. IR has been used to identify co-morbidities,[3] smoking status,[4] as well as detecting fall-related injuries.[5] Regular expressions have been used to extract blood pressure values from progress notes.[6] Natural language processing (NLP) has been used to extract medical information such as principal diagnosis[4] and medication use[7] from clinical narratives. This work has led to a better understanding of the conditions patients face and how to treat them.[8]

Raw medical text passages are voluminous and heterogeneous as is their structure.[9] Some of the information is in free-text form, written as full sentences or phrases, but much of it is in the form of semi-structured data, or templates.[10] Semi-structured data is defined as data that has some structure but is inconsistent or does not adhere to any rigorous format.[11] While some work has been done extracting information from semi-structured data, most of that research focused on extracting data from web pages or research articles and is not easily adapted to the medical domain.[12-15] Part-of-speech parsers in off-the-shelf NLP programs do not perform well on semi-structured data because it does not adhere to grammatical rules. If the structures within documents could first be accurately identified, then extraction methods that do not depend on English grammar could be developed to extract the information in these structures.

The goal of this study was to evaluate a method of processing information in semi-structured text in medical progress notes by first, classifying each line of text using machine learning, then using the line classifications in a rules-based parser, annotate the semi-structured text elements. This will allow the information in these structures to be further processed or stored in structured form. To achieve this goal, a prototype system "TagLine" was developed. We exploit non-grammatical features derived from the text in progress notes to apply a class label to each line of text and use these labels in a rule-based annotator to identify semi-structure text elements in the text. Our system combines methods already familiar in IE, such as concept look-ups, regular expressions, rules, and machine learning on features from the text to accurately identify information contained in semi-structured text elements.

Background

Information Extraction. IE is defined as the extraction of predefined types of information from text.[16] There are four primary methods available to implement an information extraction system, including NLP, pattern matching,

rules, and machine learning. The primary means of performing IE is NLP. NLP research focuses on developing computational models for understanding natural language.[17] The use of rules and pattern-matching exploits basic patterns over a variety of structures, such as text strings, part-of-speech tags, semantic pairs, and dictionary entries.[18] Regular expressions are effective when the structure of the text and the tokens are consistent, but tend to be one-off methods tailored to the extraction task. Hand coding of complex regular expressions can be a very time consuming effort that requires *a priori* knowledge of all possible patterns that represent the concept being sought. Machine learning techniques can be an effective method for IE through automated knowledge acquisition.[19] Features extracted from the text, such as parts of speech and sentence length, are fed into a learning machine to assist in tasks downstream like word sense disambiguation. The primary disadvantage of using machine learning is that it requires a labeled dataset for training a model.

Semi-Structured Data. Well-structured data, as found in a typical database, conforms to a schema or data model and can be queried using a structured query language to answer questions. Semi-structured data is data that has some structure but is inconsistent or does not adhere to any rigorous format,[36] and is very difficult to query. In semi-structured data, information normally associated with a schema is contained ***within*** the data, which is sometimes called "self-describing."[11] Semi-structured data can break the conventions for structured data in a number of ways. The structure is often irregular, implicit, or partial.

Table 1. Previous work on semi-structured data

Method Used	Document Type
Finite state machines[20]	HTML

Link grammars connect features with numbers	EHR
ID3 trees on NLP features[34]	EHR
Standard data cleansing techniques[35]	EHR

Efforts to perform IE on semi-structured data are well developed for web pages but less so on research articles from peer-reviewed journals and notes for the electronic medical record. Table 1 shows a summary of the published methods previously used for extracting semi-structured data. Pages on the World Wide Web are written in HTML, which is a standard and provides a healthy measure of reliable structure that these studies used in developing extraction routines. Research papers also adhere to a certain amount of structure. There is an order to the flow of the paper and very specific formatting conventions with journals for section headers, graph labels and tables. For IE on semi-structured data in the electronic medical record, the work is limited and it has been noted that locating the data is difficult, since no standard way to enter the data in the EHR system is reinforced. Furthermore, there are no built-in edit checks available to facilitate data entry.

The Electronic Health Record at the VA. The VHA EHR, VistA, records information regarding a patient's clinical encounters, in both structured data tables and text. Each line of 80 characters or less is stored as a string associated with a specific document, such as a medical progress note. This preserves the formatting of the document to make it easier to read in the Computerized Patient Record System (CPRS),[37] the user interface for VistA. It also provides an artifact useful in text processing. Each note can be separated into a group of individual lines of text. Because progress notes are written for a variety of purposes, notes are assigned descriptive names. Users can create their own custom designed notes using the Progress Notes Construction Set[38] and design their own templates for the notes. This causes tremendous variation in the way notes are structured, which means developing extraction routines using techniques like regular expressions and handcrafted rules are typically useful only as one-off solutions.

Document element ontology. This study is guided by an ontology developed by investigators in the Consortium for Health Informatics Research (CHIR) to define the text elements to be targeted. The ontology described here is the result of an error analysis from the 2010 i2b2 challenge submission and a CHIR Information Extraction Methods (IEM) initiative.[39] A document is made up from a set of document elements. Sections, slot-value pairs, paragraphs, sentences, phrases, content, questions, lists, tables, and address blocks are examples of document elements. Figure 1 graphically depicts a sample of the structures and their component parts. For purposes of this study, we selected the text elements tables and slot-values. Table 2 presents a sample of the line-of-text classifications being used, along with the parent "is-a" class from the text element ontology and the larger structural (part-of) class. It gives the relationship of the line type to structure type in "is a" or "is part of" relationships. There were a total of 75 distinct class labels derived from the text and ontology.

Table 3. Sample line classes and their relationships to document elements.

Line Class	Is-A	Part-Of
Double Xed Items	CheckBox	Question
Multiple Xed Items	CheckBox	Question
Xed item	CheckBox	Question
Line list with Header	List	List
Comma separated list on a line	List	List
List Header	ListHead	List
Numbered Item	ListItem	List
Medication Footer	MedFooter	Table
Medication List Directions	TableRow	Table
Med List Item (not numbered)	TableRow	Table

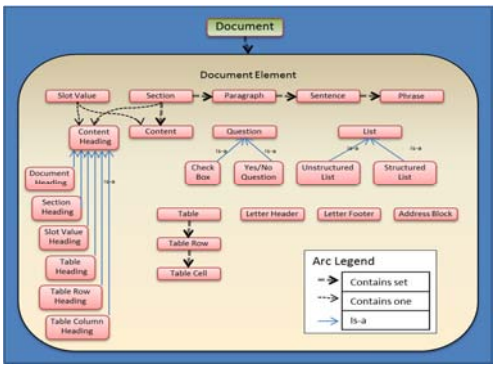

Figure 1. Document element ontology

The Line of Text as the Unit of Analysis. Progress notes in VistA are stored as a series of strings at a length of 80 characters or less. These text strings can be assigned recognizable roles as defined in the text element ontology. Some of these elements stand on their own as atomic text elements, while others are part of larger more complex text element structures. Both tables and slot values can be defined by their constituent parts. Slot values consist of a content heading and content separated by a delimiter and can be contained within a single line of text. Slot value content is a short value, typically a word, numeric value or phrase. The elements of a table can be identified by their parts at the line level. A table, as defined by the document element ontology, is a collection of related items arranged in columns and rows. Tables may have column labels and row labels as well as a caption for the subject of the table. The first line in Table 5, `"---- CBC PROFILE ----"` stands complete as the table header (THE). The second and third lines are used to label the information in the columns (CLA). The remaining lines are each identifiable table items (TBI) in the table.

Table 4. Table Example

Class	Line of Text			
THE		---- CBC PROFILE ----		
CLA	BLOOD	01/19		Reference
CLA		14:20	Units	Ranges
TBI	WBC	5.7	G/L	4.2-10.3
TBI	RBC	4.8	T/L	4.2-5.8
TBI	HGB	14.2	g/dL	14-17
TBI	HCT	43.3	%	39-50

Table 5. Slot Filler Examples

Class	Line of Text
SLF	CURRENT LEVEL OF PAIN: 5
DSV	LMP:11-26-06 PMP:221
TSV	Grava: 2 Para: 2 Abortion: 0
SLT	Indicate HOW YOUR PAIN FEELS:
FRT	Aching

The basic slot-filler consists of a label and a value separated by a delimiter, usually a colon (see Table 6). In its simplest form the slot-filler appears as shown on a single line. This line would be given the label "SLV" for slot-filler or slot-value pair. However, slot-fillers do not always appear in this form; there may be two or three sets of slot-fillers on the same line. These two examples are then labeled "DSV" and "TSV" respectively, for double slot-filler and triple slot-filler. The two elements, the label and the value may also appear on separate lines. The values that fill the slot are not always present, so there may only be a slot. Since each line tends to stand as a unit, we chose this as our unit of analysis in machine learning. Each of these variations must be handled by a specific set of parsing rules, and the class labels identify which set of rules to employ.

Table 6. Feature Examples

Feature	Description
AllCaps	All uppercase letters
Title	In title case
NumCaps	Number of uppercase letters
Hyphens	Number of hyphens
Spaces	Number of spaces
Slashes	Number of slashes
DecPos	Offset position of decimal
ColPos	Offset position of colon
QmPos	Offset position of "?"
Bar	Formatting bar
YesNo	Ends with "Yes" or "No"
Icd	Presence of IDC9 code
Bullet	Line is bulleted
Numbed	Line is numbered

Feature selection. The selection of features that were used in machine learning to assign classes to each line was crucial to success. We reviewed the work of other studies in this area[20,40-42] and derived and tested a number of additional features to detect structure in lines of text. Table 6 shows a sample of the features we adopted. We looked for similar clues in each of the text elements that help us tell them apart from other text elements. These clues fall into one of several types of text features: formatting features, special character usage, term usage, and document structural features. Examples of formatting features include whether the line was in all uppercase letters or in title case, as well as the number of uppercase letters in the line. Special character features

included items such as the total number of spaces, slashes, and hyphens in the line and where the first, second, and third decimal and colon could be found in the line. Examples of term usage-based features included position of a question mark, if the line of text ends with a "Yes" or "No" and if the token "ICD" was found in the line. Finally, document structural features included items such as if a line was numbered, had a text bullet, and if a line had a formatting bar (e.g., **********). In all, there were over 70 features defined to describe the differences between classes.

Data Preparation

Document Selection. A set of 162 notes formed the corpus for this study. These notes are a subset of the 5,048 medical progress notes collected in a separate and unrelated study in the VHA to identify patients who have suffered a fall-related injury[5]. The notes were randomly selected from note types containing the greatest number and variety of semi-structured text elements. The variety of note types selected represents note types that are most frequently used in the VHA for treatment of falls, primarily notes from emergency room and primary care visits. They included "Primary Care Notes", "Primary Care Nursing Notes", "Primary Care H&P Notes", "Primary Care Home Health Consult Notes," "Emergency Room Nursing Notes", "Emergency Room Triage Notes" and "Nursing Discharge Notes." These note types tend to have more structured elements than those written in free text. To evaluate machine learning on assigning line classes, all lines (n=15,103) from the selected notes were randomly split into sets of 10,000 and 5,103 for training and test respectively. To evaluate the structure annotator on identification of targeted semi-structured data, the 162 notes were randomly split into 115 notes for training and 47 notes for testing.

Labeling Lines of text. To provide data for machine learning each of the 15,103 lines in the 162 notes, classes were assigned to lines of text as an intermediate step to finding and extracting information from specific predefined types of semi-structured text elements. Class labels were determined by membership in or relationship to, the structure types defined in the CHIR ontology, and were derived empirically from the text. The classes may describe a part of a structure, such as a table or contain multiple structural parts. Class determination and text line labeling were iterative simultaneous tasks. First we examined the line for a relationship to a structure type in the ontology. If there was a class that describes this relationship, then we applied that class. If not, we created a new class within the ontology that describes the relationship and apply the class label. Structure types in the ontology can be associated with multiple classes of lines. This is grounded in the fact that any given structure type identified by the ontology may appear in the text in multiple forms as in the slot-fillers example above. Rigorous steps were taken to ensure that the classes were unique and that they related to only one text element in the ontology. Each class was evaluated individually and discussed as it was added to the set. As the number classes grew we evaluated their usefulness them by using them in some preliminary machine learning models. Classes that were misclassified were re-examined and if the label applied by the machine learning model was valid, it was relabeled with the predicted label. If the label was not valid, then we applied a new label and new features were added to the machine learning models to improve performance.

When the labeling was completed a count was made of each occurrence of each class and the distribution of the class frequencies was checked. It was found in initial models developed that classes with fewer than six instances in the dataset achieved an F-Measure of less than 0.6. Classes with less than six occurrences in the dataset were removed and the lines with those labels were re-labeled with the next best class. This required that the new class label be re-defined to include the new instances. There were a total of 75 possible class labels derived from the text and ontology. A total of 13 classes were eliminated from the list, leaving 58 remaining classes for use in machine learning models. None of the removed classes were relevant for the structures examined in this effort. The classes that most frequently appeared in the text were free text (FRT), slot-value (SLV), medication list item (MLI), and table item (TBI). Since the annotator uses the predicted line labels in its parsing routines, the errors in line label predictions are likely to cause errors in the structural annotations. It is therefore crucial to achieve the highest possible prediction accuracy in the first step.

TagLine

To accomplish the goal of this study, the prototype TagLine system was designed and implemented. TagLine consists of a series of interacting software modules written in Python. Shown in Figure 2, the paths in yellow show the flow sequence for training a new model and the blue paths show the sequence for structure annotation.

Extraction Module. Notes are converted to a list of text lines and each text line is subjected to a series of functions that extract values for the features to be used in machine learning. When a new model is trained, all features are selected for extraction. The final model determines which features will be extracted when using the system for annotation. The resulting new dataset was used to train the learning machine and make predictions. Each line in the dataset described a line of text in the note. This dataset was sent to the C5.0 module when training a new model or to the next stage for use in classification by the tree classifier.

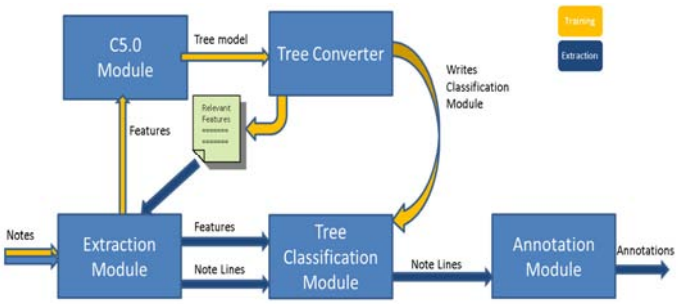

Figure 2. TagLine system architecture

C5.0 module. Decision trees are a good fit for the work in this study for the following reasons[43]: They handle high dimensional data well, are computationally efficient, easily interpreted by human beings, and most importantly for this study, can be readily converted to computer executable code. This study uses an updated version of the C4.5 algorithm developed by Ross Quinlan as C5.0.[44] The C5.0 module is a Python wrapper for a console application. The C5.0 application was compiled from the GPL C code distributed freely by Ross Quinlan. The C5.0 module develops a decision tree model based on the features provided by the extraction module. The C5.0 algorithm performs winnowing of the attributes before building a tree by evaluating each attributes' effect on error rate when the attribute is removed. Error-based pruning is also performed to cut back on branches that do not contribute to the models overall efficacy. Finally, this module writes a tree model file out to disk for use later.

Tree converter module. The tree converter parses the original tree model file written by the C5.0 module and writes two new files; a text file and a Python executable classification module. The text file is a list of the features determined by the C5.0 decision tree model found to be useful in prediction. When the new classification module is used, the extractor will only extract those features that are needed.

Tree classification module. The tree classification module is automatically created by the tree converter module by parsing the tree model and writing executable Python code. This module takes the note as a list of text lines and classifies them using a series of if-then rules. Then it passes the classification results along with the lines of text to the annotation module.

Annotation module. The annotation module takes the classification results and the lines of text from the tree classification module and uses them to locate structures in the text based on options submitted by the user. For each type of structure indicated in the options, the annotation module loops through each line of the note looking for the appropriate line labels for the targeted structures. When targeted labels are encountered, a rule-based approach is used to parse and annotate the structure and return values in the form "ElementType|StartOffset|StopOffset." The annotations can be written to a file for review, recorded in a database for storage and used later as structured data, used as features in another classification task downstream, or sent to an NLP pipeline where annotations can be used for extracting concepts from the text elements using a structured vocabulary. TagLine can also extract the elements and record the notes with the annotated structures removed as a text reduction method.

TagLine Evaluation

TagLine was evaluated in two separate experiments. First, we evaluated the use of decision trees for predicting the classes assigned to the lines of text, then we evaluated the accuracy of our rules based annotator for identifying slot-value pairs and tables based on the classes assigned to the lines.

Results for Line Classification. A decision tree was constructed on the line-level training data and evaluated on unseen test data for prediction accuracy. Winnowing was used for feature reduction before a tree was constructed. Winnowing removes any feature that does add to the models efficacy. The C50 algorithm constructs an initial model on half of the training data and calculates the increase in error rate for each feature when it is left out of the model. Global pruning was performed after tree induction keeping only those branches that had at least one instance associated with it. Error based pruning was also employed; a branch was pruned if its prediction errors exceeded a

level of 25 percent. A series of fifty models were tested using graduating numbers of lines in increments of 200 examples starting at 200 and ending with 10,000. The overall prediction accuracy was calculated for each test using a hold out set of 5,103 lines. The results are presented as a learning curve in Figure 4.

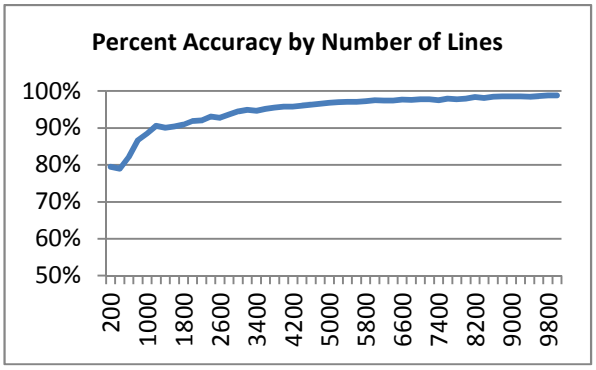

Figure 3. Learning Curve for Machine Learning

Table 7. Line Classification Statistics

Class	N	Precision	Recall	F-Measure
Free-text	934	0.9789	0.9936	0.9862
TableItem	900	0.9944	0.9878	0.9911
Slot-filler	508	0.9882	0.9882	0.9882
MedLine	362	0.9564	0.9696	0.9630
Slot	273	1.0000	0.9963	0.9982
AphaLine	6	0.8333	0.8333	0.8333
NumbedQue	4	0.8000	1.0000	0.8889
NumbMed	3	0.6667	0.6667	0.6667
LabeledDS	2	0.6667	1.0000	0.8000
QuestHead	1	0.5000	1.0000	0.6667

With a sample size of 200 lines, the decision tree model was able to achieve an accuracy rating of 80 percent. The accuracy increased to 90 percent at 1,200 lines. An overall accuracy level of 98.5 percent was achieved with a sample set of 10,000 lines, only 3.5 percent higher than at the 3,000-line sample size. The performance results for the five most and least frequent classes in the test set are shown in Table 7. Only five classes did not achieve an overall F-measure of 0.9 or above.

Prior to tree construction, the winnowing process eliminated 20 features. The top 10 remaining features are shown below in Table 8 with their respective importance ratings. The importance rating is C5.0's estimate of the factor by which the true error rate or misclassification cost would increase if that attribute were excluded. The number of colons in a line of text appears to be the most important feature in the model. Colons are important when looking for slot-value pairs, as well as dates and timestamps. The second most predictive feature is the line number for the line of text. Line numbers describe how far into the note a line appears; beginning, middle or end. Interestingly, all of the tests done by the model using the line number feature took place at the top of the note (see figure 4). Question marks, capital letters, and white space gaps also help in distinguishing structured text from un-structured text.

Table 8. Top 10 Features

Importance	Feature
835%	Colons
264%	LNum
255%	Slot
179%	LSpc
166%	Bull
150%	Med
148%	Gaps
139%	QM
137%	Caps
127%	Time

```
QM > 0:
:...Quest > 0:
:   :...LNum > 0: NQU (10)
:   :   LNum <= 0:
:   :   :...Colons <= 0:
:   :       :...SLow <= 0: QUE (268)
:   :       :   SLow > 0: QUF (28)
:   :       Colons > 0:
:   :       :...UpSlot <= 0: HQU (4)
:   :           UpSlot > 0: SLV (1)
```

Figure 4. Decision Tree Fragment

The occurrence of a question mark was the most used feature in the model. This is shown in the tree fragment in Figure 4 where the feature QM is at the top of the decision tree, indicating it is the first attribute the tree splits on.

The tree classification module was used to predict the 5,103 line class labels in the test data. Many classes achieved a perfect score. The poor performers were all low prevalence classes, each occurring less than ten times in the entire test set. The class ALI is alpha list item, or an item in a list that is delineated by an alpha character and some delimiter. One line labeled ALI was misclassified as FRT causing one false negative. The only feature that would distinguish Free-text from an alpha-labeled-line is the use of the delimiter after the delineating character. In most applications a 95 percent accuracy rate would be considered acceptable, so it would not be necessary to use more than 3,000 lines for an acceptable result. However, because the results of the annotation in TagLine is dependent on the accuracy of the line labels it was decided to use the full 10,000 lines for the training set and the remaining for testing in the next section.

Results for Annotating Tables and Slot-Fillers. For this experiment, the data were split into training and test sets segregated at the note level. In the next stage, the parsing routines were tested on two types of structures; slot-value

pairs and tables. Since tables are multi-line units, all lines are needed to identify a unit. There were a total of 115 notes and 10,048 lines of text in training set, while the test set had the remaining 47 notes and 5,055 lines of text. A record was constructed noting the number of tables, slots and fillers in the 47 notes. Table 6 shows the occurrences of each structure in the note set. The test set of notes has a total of 96 tables, 770 slots and 566 fillers for the slots. Not all of the slots have fillers associated with them so the numbers of slots and fillers will not match. The complete set of 47 notes was used in a GATE pipeline that called TagLine using a remote procedure call (RPC) server.

As the notes were processed, the server recorded the annotation actions. The extraction results were compiled for evaluation. Table 9 summarizes performance of TagLine on tables, slots, and slot fillers. The TagLine server reads the options, extracts the features from the note, uses the prediction module constructed from the decision tree, applies class labels to the lines, and returns the annotations on the structures found. When tables are targeted, start and stop rules are used to identify the boundaries of the table. The routine sequentially examines the labels applied to each line and when a class is encountered that signals the beginning of a table, a flag is set and all successive lines are included until a line label signaling a stop rule is encountered and the table end boundary is set and the annotation is returned. If a line in the middle of the table is classified as free text, it would prematurely trigger the table's end and close off the boundaries of the table and erroneously start a new table at the next table line. For this reason, a rule was included to allow for a one-line misclassification gap in the table. While traversing the lines of text after a table beginning has been encountered, if a line is found that is not a table line, the end of table is marked, but held until the next line is checked. If the line after the non-table line is a table line then the table end is cleared and the boundary of the table is extended until there are no more table lines. In the event the next line is a table header or a column labels, then the current table is completed and a new table begins. A constraint enforced by this method is that a table must have at least one table line (TBL) to be annotated as a table.

Table 9. TagLine Annotation Performance

		Exact Match			Partial Match		
Structure	**Count**	**Precision**	**Recall**	**F-Measure**	**Precision**	**Recall**	**F-Measure**
Tables	96	0.9250	0.9250	0.9250	0.9896	0.9896	0.9896
Slots	770	0.9709	0.9974	0.9840	0.9735	1.0000	0.9865
Fillers	566	0.9543	0.9965	0.9749	0.9560	0.9982	0.9767

Discussion

TagLine performed well on slots and fillers. There was little difference when evaluating performance on exact versus partial matching criteria. There were 770 slots in the 126 notes used for the test. TagLine found 768 of the slots matching the start and stop end points exactly. The two remaining slots were found but the parsing routine failed to set the offsets properly. One was due to colon placement in the string. The text line in the middle of the note: "`(R): 0.7cm X 0.5cm  (L): cm X cm`" was marked as a DSV, or a double slot value. The "`(R):`" is the slot, and the filler is "`0.7cm X 0.5cm`." TagLine failed to parse this line appropriately for both of the slots and fillers. While they were found, they were not considered exact matches. There were 21 false positives for slots. A total of 19 of the false positives were due to date entries across several notes that were misclassified as slot-values. There were a total of 566 fillers in the 47 test notes. TagLine successfully annotated all but one of the fillers, but there were 26 false positives, 19 associated with the date misclassifications mentioned above, resulting in a lower precision (0.9543) than recall (0.9965). Figure 5 shows the slot-filler annotations highlighted for one of the test notes.

There were 96 tables distributed throughout the 47 test notes. TagLine achieved an F-measure of 0.9250 for exact matching, lower than the number achieved for slots and fillers, but encouraging. Of the 96 tables in the test set, 86 were matched exactly according to the start and stop codes. Of the remaining 10 tables, 9 were identified with partial matches and one table was missed completely. Many partial match cases were due to column labels (CLA), or table item (TBI) being misclassified as free text (FRT), causing the parser to miss that portion of the table. In Figure 6, it can be seen that three lines in the table were not annotated. The first of the three is the column label and the next two descriptive entries did not conform to the format of the other table lines and were labeled FRT. Because the lines "`color yellow`" and "`appeara sl cldy`" do not conform to the format of the rest of the table, the table was partially captured in two parts. An allowance is made in the case that one line is misclassified, so tables are not broken apart. However, if more than one line is misclassified then the table will only be a partial match. Making allowances for more than one misclassified line causes problems when tables are found stacked directly on top of another table. In these cases, the two tables erroneously become one contiguous table.

Conclusions

TagLine was evaluated for parsing and annotating semi-structured text elements both at the macro level, on multi-line structures, and at the micro level, on within-line structures. TagLines' performance identifying slots and fillers was impressive. The annotator achieved an F-measure of 0.9840 for exact matching criteria for slots and 0.9965 for fillers. The results for tables were not as impressive, achieving an F-measure of 0.925 for exact matches and 0.9896 for partial matches. Since even partial matches are likely to be useful in practice, the results were quite good.

Contributions. In this study, we have shown how using the line of text as the unit of analysis can play an important role in semi-structured elements and that text analysis can be beneficial at this level. TagLine has been shown to be effective for distinguishing specific classes of lines based on their structural roles and for identifying semi-structured text elements in medical progress notes. This will enable researchers to use more of the information in the text than was possible before. The information in the annotations can be stored in a database and used for other analyses as fully structured data. Once identified, semi-structured text elements can also be removed from the document so NLP can focus on the free-text sections which may result in more accurate concept extraction, as well as faster processing times for each note. The counts of these structures could be used as features in a machine learning approach for document classification tasks. TagLine can now be used to do ad hoc concept extraction from the semi-structured text by using rule as implemented in the JAPE module of GATE. Rules such as "if slot = <search term> lookup <filler>."Only those structures that contained the search terms or concepts would be annotated and returned. Since more information can be extracted from the notes, more complete information is available for patient analysis or document classification. This additional data could enable researchers to explore topics better and perhaps improve the healthcare for veterans easier and faster than before.

Limitations. This study has two primary limitations. First the dataset, while adequate for purposes of providing sufficient examples for developing and evaluating learning machines, is still limited since the sample was taken from an existing study and may not include many note types and their specific challenges. TagLine needs further testing and development to ensure good generalizability. Also, samples of documents from other hospitals should to be included in the corpus to train models for increased generalizability.

Future Work. The parser in TagLine will be expanded to include other types of structures like full templates, questions and checkboxes. The language across note sections tends to differ.[45] This feature is often used in NLP systems for "word sense disambiguation," and is a fertile area for research[46]. There is a need to improve section identification or section header identification.[47,48] We will also extend Tagline to function as a "sectionizer," which accurately determines which section of the note a line of text belongs to. A sectionizer would be useful in word sense disambiguation and for text reduction, potentially saving significant amounts of time and money on creating annotated data sets. Human annotators would have smaller, more concentrated notes to cover if it is known that certain sections held no interest. This may increase productivity by shortening the time necessary to cover the note

and decrease the likelihood of mental fatigue that occurs with longer notes, as well as reducing the amount of time spent on irrelevant documents.

Abstract

Alarm fatigue caused by false alarms and alerts is an extremely important issue for the medical staff in Intensive Care Units. The ability to predict electrocardiogram and arterial blood pressure waveforms can potentially help the staff and hospital systems better classify a patient's waveforms and subsequent alarms. This paper explores the use of Echo State Networks, a specific type of neural network for mining, understanding, and predicting electrocardiogram and arterial blood pressure waveforms. Several network architectures are designed and evaluated. The results show the utility of these echo state networks, particularly ones with larger integrated reservoirs, for predicting electrocardiogram waveforms and the adaptability of such models across individuals. The work presented here offers a unique approach for understanding and predicting a patient's waveforms in order to potentially improve alarm generation. We conclude with a brief discussion of future extensions of this research.

1. Introduction

Intensive Care Units (ICUs) are designed to handle some of the most physiologically fragile patients in the hospital. As a result, ICUs utilize a wide spectrum of machines, technologies, and tests to help medical staff better understand and care for patients. However, the wide array of stand-alone machines often collect data and produce alarms and alerts independently, leaving the difficult integration tasks for the medical staff[1]. Time sensitive decisions, including identifying non-critical alarms, are just some of the problems faced by ICU medical staffs. Studies have shown that staffs in ICUs face an extraordinary number of alarms each day, some as many as 1,000 alarms a day, many of which are non-actionable or not necessary for patient care[2,3]. Excess amounts of non-critical alarms can lead to alarm fatigue which can adversely affect patient care[4-6]. While there is ongoing research to effectively minimize false alarms, such as allowing nurses to adjust alarm thresholds, much work is still needed to improve classification techniques and systems in order to reduce false alarms[5,7]. A remaining challenge is to develop algorithms robust enough to understand, integrate, and predict multiple physiological waveforms from patient data to better classify and interpret alarms.

The purpose of this paper is to explore the value of using of Echo State Networks (ESN), a particular type of recurrent neural network, to predict an individual's waveforms. Being able to forecast an individual's waveform could potentially offer much more information to the medical staff in addition to alarm classifications. ESNs were chosen because of their ability to accurately predict chaotic time series[8-11]. In our research, these networks were trained to predict an individual's electrocardiogram (ECG) and arterial blood pressure (ABP) waveform data, which can potentially help prioritize alarms as well as predict life-threatening situations in the ICU. Our research uses clinical ICU patient data to develop, train, and test various ESN architectures for prediction tasks, and establishes the benefits of using ESN architecture designs for predicting ECG and ABP waveforms. Waveform and alarm classification and prediction is very important and we hope that this work will be helpful in providing additional insight into this problem.

2. Background

The recent release of clinical ICU patient data Multiparameter Intelligent Monitoring in Intensive Care II(MIMIC II) makes it possible to develop better models and support tools to aid medical workers in understanding and filtering the abundance of information and alarms[11]. This publicly available database has already been analyzed and used in several ways, for example to develop decision support systems to better categorize and classify mortality rates in the ICU[6, 11-14]. A study previously used this data and an expert review panel to reclassify five common ICU alarms into true alarms and false alarms. These authors then developed an algorithm that classified alarms based on both electrocardiogram (ECG) and arterial blood pressure (ABP) waveforms immediately prior to the machine generated alarms. When tested, the algorithm suppressed approximately 59.7% of the false alarms and 0% of true alarms (except for true ventricular tachycardia alarms which was reduced by 9.4%)[15]. While their algorithm is focused on classification, this project aims to complement their work by developing a neural network that can learn to predict

the more continuous waveforms. An effective predictive model can help medical staff better anticipate a patient's condition, which includes the occurrence of alarms and false alarms.

It is difficult to predict time series data, especially with chaotic waveforms such as ECG and ABP. Previous studies that have focused on predicting ECG and ABP waveforms have used structures or approaches that simplified the waveforms, usually with higher order measures[15-19]. While there have been previous studies modeling and predicting complex time series, only a few studies have explored the relationship between ECG and ABP waveforms during classification or prediction tasks[15, 20-24]. Our work explores the use of ESNs, a type of recurrent neural network, to explore this ECG-ABP relationship further. Neural networks have been shown to be good at predicting time series data, especially in situations where building proper heuristic models is difficult[25-27]. ESNs were chosen for this research because they have been previously shown to accurately predict chaotic time series without the need to train the specific internal representations of the system[9, 10]. This computational advantage makes ESNs very attractive for predicting ECG and ABP time series which are both chaotic and difficult to learn.

2.1 Echo State Network

An Echo State Network (ESN), Figure 1, is an example of a recurrent neural network capable of modeling and predicting non-linear behaviors[9, 10]. A typical ESN has four sets of unique weights: W_{in_hidden}, W_{hidden}, W_{hidden_out}, and W_{in_out}. W_{in_hidden} are randomly assigned fully connected weights between the input node to the reservoir nodes. A distinct property of ESNs is the sparely connected, randomly assigned weights between the reservoir nodes, W_{hidden}. These sparsely connected nodes allow for pockets of local resonances, or echoes, to develop, which together can model complex waveforms[9,10]. Furthermore, W_{hidden_out} are randomly assigned fully connected weights from the reservoir nodes to the output node which contributes to the learning of the network from the teacher (or training) signal. Unlike more typical recurrent neural networks, ESNs do not have connections from the output nodes back to the hidden nodes; this greatly reduces the model complexity and convergence time for ESNs[10].Lastly, W_{in_out} are randomly assigned weights from the input node to the output node.

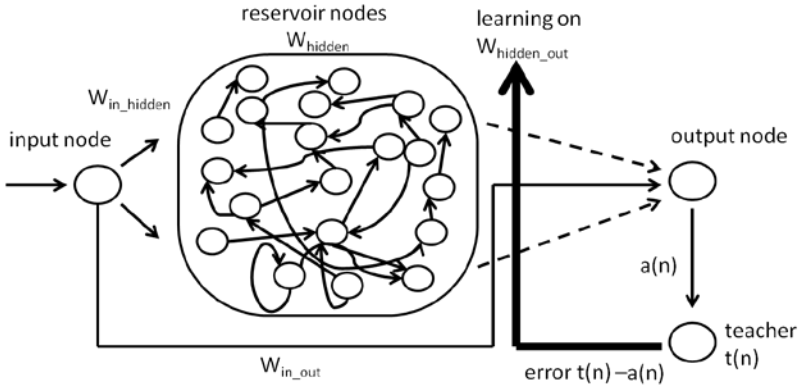

Figure 1: ESN architecture with learning on W_{hidden_out} (dashed arrows).

3. Methods

We comparatively evaluate the performance of three different types of ESN architectures at predicting two related physiological waveforms. The following sections first describe the data and preprocessing of the data. Next we discuss the analysis to identify reasonable ranges for key model parameters (reservoir size, activation rule, and learning rates). We then describe the three ESN architecture designs and our evaluation criteria.

3.1 Data Source and Pre-Processing

The data used for this project comes from the MIMIC II database which is publicly available[11, 14, 28]. The complete database currently contains data from approximately 33,000 de-identified patients collected over 7 years (beginning in 2001) from Boston's Beth Israel Deaconess Medical Centers. It combines both clinical and physiological data. The adult patients range in age from 18 to over 90 years old (mean 68 years), and were collected from 48 medical, surgical, and coronary intensive care beds. Each patient record typically contains data from two electrocardiogram (ECG) leads, arterial blood pressure (ABP) and pulmonary arterial pressure (PAP) stored at 125Hz over time intervals that can range between a few hours to a few days. The ECG was originally sampled at 500Hz but was compressed to 125Hz while still preserving the peaks[15]. The resulting database is quite large (over 3TB). Because

we were interested in evaluating ESNs for individual patients, we focused on data from the ECG II (ECG lead II) and ABP readings from six randomly selected patients. ECG II data was selected because it appeared to be more available from a cursory look at the patient records. ABP was selected because of its relationship to ECG in the interpretation and classification of alarms[15].

Although the data is publicly available, a specialized WaveForm DataBase (WFDB) software package was required to download, interpret, and format the data[29]. Cygwin was used to connect directly to the server to download and format the data. The downloaded data was converted to comma separable version files which were compatible with Matlab. Some basic preprocessing was needed to make the magnitudes for the two waveforms comparable. A simple smoothing function, that averaged the data points in a 5-time step moving window, was applied to both the ECG and ABP data. This window size was effective at smoothing the waveform while maintaining the important features of the waves. The ABP data was also normalized to fall within the values 0 and 1. The ECG was vertically shifted up by the minimal value so it would be within the same range as the ABP data. These transformations were necessary in order to make the two waveforms similar in magnitude while maintaining unique features to allow for comparison.

3.2 Defining Baseline Model

An Echo State Network (ESN), Figure 1, was first built in Matlab based on previous work[9, 10]. Weights were initially assigned random values between -0.5 and 0.5. Similar to previous work, approximately 20% of the possible connections in the reservoir have non-zero weights and are scaled with a spectral radius of 0.98, using:

$$W_{hidden} = \frac{\alpha W'_{hidden}}{|\lambda_{max}|}$$

where α is a scaling factor, W'_{hidden} is the weight matrix for the reservoir prior to transformation, and $|\lambda_{max}|$ is the maximum eigenvalue of W'_{hidden}, i.e., the spectral radius[10].

The activation for the hidden nodes, A_{hidden}, and output nodes, A_{out}, is[10]:

$$A_{hidden}(t) = tanh(W_{in\_hidden}A_{in}(t) + W_{hidden}A_{hidden}(t\text{-}1))$$

$$A_{out}(t) = W_{in\_out}A_{in}(t) + W_{hidden\_out}A_{hidden}(t)$$

The learning rule and training only applied to the connections between the hidden nodes and the output nodes; all other weights remained unchanged through initialization, training, and testing. Although various learning techniques to train these weights were tried, such as linear regression and simplified error back propagation, a simple delta learning rule that incrementally changed the weights based on the product of the learning rate and the training error was shown to be both effective and fast. To prevent excessive oscillations in weights, a minimal error threshold was applied such that weights would not change if the absolute value of the error was less than 0.0001 (determined empirically).

To help validate this initial implementation, it was first tested by training it to model a simulated sine wave. The data was divided into training data (2,000 time-steps) and testing data (1,000 time-steps). The ESN, with 600 reservoir nodes and a learning rate of 0.0001, was initialized by passing the simulated sine wave through the reservoir once to let the internal system transients dissipate. Next, the training data was introduced to the network and the hidden-to-output weights were allowed to learn. The goal was to develop a model that could predict a waveform; hence the teacher signal to be predicted was the input signal 100 time-steps to the right (i.e., 100 time-steps in the future). This trivial example demonstrated the basic workings of this network. Mean Square Error (MSE) was used to evaluate this and subsequent test predictions:

$$MSE = {}^{1}/_{N}\sum_{n=1}^{N}\big(t(n) - a(n)\big)^2$$

where N is the total number of time-steps in the test prediction, *t(n)* is the actual teacher value at time-step *n*, and *a(n)* is the output predicted value at time-step *n*. This trivial but useful prediction demonstration resulted in a low MSE test of 0.025.

3.3 ESN Architecture Designs

Three ESN architectures were designed to predict ECG and ABP waveforms. Three architectures were chosen to explore how coupling and integrating related waveforms effects overall predictive performance, Figure 2. The first
